MEDAL (Fr. médaille, from Lat. metalum), strictly the term given to a memorial piece, originally of metal, and generally in the shape of a coin, used however not as currency but as an artistic product. "Medallion" is a similar term for a large medal, but is now usually restricted to a form of bas-relief in sculpture. The term "medal" is, artistically, extended by analogy to pieces of the same character not necessarily shaped like coins. The history of coins and medals is inseparable, and is treated under the general heading of Numismatics. That article may be supplemented here by an account of (1) the more recent progress in the art of the medallist, and (2) the use of medals for war decorations.

The medal—as it is understood to-day—enjoys a life entirely independent of the coin on the one hand, and, on the other, of the sculptured medallion, or bas-relief; and its renaissance is one of the chief phenomena in art during the period since about 1870. It is in France that it has risen to the greatest perfection. Its popularity there is well-nigh universal; it is esteemed not only for memorials of popular events and of public men, but also for private celebrations of all kinds. No other nation approaches in excellence—in artistic feeling, treatment, and sensitiveness of execution—the artists and the achievements of France. In England, although the Royal Academy seeks to encourage its students to practise the art, the prize it offers commonly induces no competition. The art of the medallist is not properly appreciated or understood, and receives little or no support. The prevailing notion concerning it is that it consists in stamping cheap tokens out of white metal or bronze, on which a design, more or less vulgar, stands out in frosty relief from a dazzling, glittering background. These works, even the majority of military and civic medals, demonstrate how the exquisite art of the Renaissance had been degraded in England—almost without protest or even recognition—so that they are, to a work of Roty or Chaplain, what a nameless daub would be to a picture by Rembrandt or Velasquez.

It is probable that Jacques Wiener (d. 1590), of Belgium, was the last of the medallists of note who habitually cut his steel dies entirely with his own hand without assistance, though others in some measure do so still. Although most modern workers, exclusively: medallists, have themselves cut dies, they now take advantage of the newest methods; and the graveur en médailles has become simply a médailleur. His knowledge of effect is the same—though the effect sought is different; in earlier times the artist thought chiefly of his shadow; now he mainly regards his planes. Otherwise his aims are not dissimilar. At the present day the medallist, after making conscientious studies from life (as if he were about to paint a picture), commonly works out his design in wax, or similar substance, upon a disk of plaster about 12 or 14 inches in diameter. From that advanced model a simple mould, or matrix, is made, and a plaster cast is taken, which enables the artist to complete his work in the utmost perfection. Then, if a struck medal is required, a steel cast is made, and from that a reduction to the size required for the final work is produced by means of the machine—the tour à réduction. It is this machine which has made possible the modern revival, and has revolutionized the taste of designers and public alike. It was invented by Contamin, who based it upon that tour à portrait which Houlot produced in 1766, and which helped to fame several engravers now celebrated. This machine was first exhibited in Paris in 1859, and was sold to the Munich Mint; while a similar invention, devised at the same time by the English engraver Hill, was acquired by Wyon for £2000, and was ultimately disposed of to a private mint in Paris. From that city comes the machine, based by the French inventor M. Ledru upon the two already referred to, now in use at the Royal Mint in London. A well-served medallist, therefore, need trouble himself nowadays about little beyond the primary modelling and the final result, correcting with his own hand only the slightest touches—refining, perfecting—but sometimes merely confining himself to giving his directions to the professional engraver.

The great majority of the artistic medals at present in the world (in the great collection of France there is a total of not fewer than 200,000 medals) are cast, not struck. There is in them a charm of surface, of patina, of the metal itself, which the struck medal, with all the added beauties which it allows of delicate finish and exquisite detail, can hardly give. But the production of the cast medal is much slower, much more uncertain, and the number of fine copies that can be produced is infinitely smaller. All the early medals were cast, being first modelled in wax, and then cast by the cire perdue (waste wax) method of preparing the dies, &c., is the same for medals as for coins, save that for larger and heavier work more strokes are required, as in the case of L. Coudray's popular "Orphée"—rather a sculpture-relief than a medal. The dies are capable of a great yield before becoming quite worn-out; it is said that no fewer than three million copies were struck of Professor J. Tautenhayn's Austrian jubilee medal of the Emperor Francis Joseph. In France, Thonelier's perfected machine, substituting the lever for the screw, has been in use for coins since 1844; but for the striking of medals the same old-fashioned screw-press is retained which had till then been employed both for coins and medals since the time of Louis XIV. In its present form the machine consists of an iron or bronze frame, of which the upper part is fitted with a hollow screw wherein works an inner screw. This screw, moved by steam or electricity, drives the dies, set in iron collars, so that they strike the blank placed between them. This machine can deliver a strong blow to produce a high relief, or a delicate touch to add the finest finish. In the Paris Mint large medals can be struck with comparative ease and rapidity. A hydraulic press of nearly two million pounds pressure is utilized for testing the dies.
MEDAL

process, and were usually worked over by the chaser afterwards; indeed, it was not until the beginning of the 16th century that dies, hitherto used only for coins executed in low relief, were employed for larger and bolder work. The medalists of those days often created in bronze or lead, and only occasionally used silver and gold as a luxurious taste began to demand the more precious metals. There is little doubt that the material to be preferred is dull metal (not or noble—sand-blasted) as the work, with all its variations of light and shade, could be better seen in the delicate grey of the surface.

The medal, properly considered, is not sculpture. Vasari was happy in his definition when he described the medallist's art as the link between sculpture and painting—that is to say, painting in the round with the colour left out. Less than sculpture, it need not be less dignified; it is the legacy by the conventions of low relief, and by compositions of composition and design, dependent on shape, from which sculpture, even when the relief is the lowest, is in a great measure free.

In the medal, otherwise than in sculpture, elaborate perspective and receding planes are not out of place. The genius of the modern Frenchman rebelled against the rule that commonly governed the medal during the decadence, and has triumphed in his revolt, justifying the practice by his success. The modern modernist is the first to aim at being decorative yet vigorous, reticent and idealised. He is less interested in the technical than it may be, and often, is all these in turn. Imagination, fancy, symbolism, may always be brought into play, allied to a sense of form and colour, of arrangement and execution. By the demonstration of these qualities the artist is to be differentiated from the skilful, mechanical die-sinker, who spreads over the art the blight of his heavy and insensitive hand and brain. So with portraiture. Accurate likeness of feature as well as character and expression are now to be found in all fine works, such as are sought only by an artist of keenly sensitive temperament. It is thus that he can stamp his seal upon and the to-day into metal beauty, historically seen and exquisitely recorded; thus that the figure on the medal is no longer a mere sculpturesque symbol, but a thing of flesh and blood, suave and graceful in composition, and as pleasing in its purely decorative design as imagination can inspire or example suggest. It is thus that the art, while offering easy means of permanent memorial, has afforded to men of restricted means the eagerly seized opportunity of forming small collections of masterpieces of art at a small cost.

France.—In France, the example of Oudiné, coming after that of David d'Angers, may still be traced. To Pontcharme (pupil of Oudiné) is chiefly due the high reputation of the greater part of the modern medalists. The subject on the medal, the suppression of the raised rim, and the abandonment of the typographic lettering hitherto in vogue, together with the mechanical regularity of its arrangement. Degeorge, with his semi-pictorial treatment, was followed by Daniel Dupuis, whose delicate and playful fancy, almost entirely pictorial, makes us forget alike the material and the die. J. C. Chaplain is unsurpassed as a modeller of noble heads, including those of four presidents of the French Republic—Macmahan, Casimir-Perier, Faure and Loubet—and his allegorical designs are finely imagined and admirably worked out (see Plate); but L. Oscar Roty (pupil of Pontcharme) is at the head of the present school of French medalists. He is master of the mystery of his technique, but also of his originality of arrangement, of the poetic charm of his symbolism and his allegories, the delicate fancy, the exquisite touch, the chasteness and purity of taste—welding a modern sentiment to an obvious feeling for the Greek. Though expressly less virile than Chaplain, Roty is never effeminate. To Roty belongs the credit of having first revived the form of the modern medal, which had been abandoned and forgotten along with many other traditions of the ancien régime (see Plate). Alphonse Dubois, Lagrange, and Borrel must be mentioned among those who are understood to engrave their own dies. Followers are Henri Dubois, Patey, Botéié (see Plate)—allSterling artists if not innovators. Medalists of more striking originality but less finish, and of less local standing, are the Micou, Chaplain, Levillain, who loves as much as Bandinelli to make over-done heads of his models, Charpentier, and their school, who aim at a manner which makes less demand of highly educated artistry such as that of Roty or of Chaplain. It is learned and accomplished in its way, but lumpy in its result; breadth is gained, but refinement and clearness are lost. The modern medalist, on the other hand, gives some idea of the industry of the modern medalist, and the encouragement accorded to him—that between 1879 and 1900 M. Roty executed more than 150 pieces, each having an obverse and reverse, of different subjects.

Austria.—The two leading medalists of the Austrian school are Josef Tautenhayn (see Plate) and Anton Scharff, both highly acclaimed, yet not, perhaps, living up to the standards of taste, ability and "keeping," which distinguishes the French medalist. About 330 pieces have come from the hand of Anton Scharff. Stefan Schwarz, Franz Pawlik, Staniek, Marschall and J. Tautenhayn, junior, are the only other artists who have risen to eminence.

Germany.—A characteristically florid style is here cultivated, such as lends itself to the elaborate treatment of costume, armorial bearings, and the like; but delicacy, distinction, and the highest excellence in modelling and engravings are qualities which accompany even the most vigorous or elaborate designs—are lacking in a great degree. Professors Hildebrandt and Kowarzik have been noted.

Belgium.—Although sculpture so greatly flourishes in Belgium, medal work shows little promise of rivalling that of France. The influence of the three brothers Wiener (Jacques, Léopold and Charles)—good medalists of the old school—has not yet been shaken off. The remarkable architectural series by the first-named, and the coinage of the second, have little affinity with the spirit of the modern medalist. The same has been true of many of the medals, followed by Paul Dubois, J. Dillens (a follower of the French G. Duvivier and Vinçotte (see Plate)—whose plaquette for the Brussels Exhibition award (1887) is original, but more admirable in design than in finish.

United States.—In this country, the names of Silas D. Dexter and E. H. F. Pawlick have come to the front. D. W. Scharff, who has called forth many medals of Queen Wilhelmina, and the best of them are doubtless those of Bart van Hove and Worman. Baars is a more virile artist, who follows Chaplain at a distance. Wiencek is interesting for the spirit of his early Netherlandish manner; the incongruity is not unpleasant.

Switzerland.—The medal is also popular in Switzerland. Here Bovy is the leader of the French tradition and Hans Frei of a more national sentiment. The last-named, however, is more remarkable as a revivalist than as an original artist.

Great Britain.—In England only two medalists of repute can be quoted—Frank Bowcher, who practises, like himself, in the line of G. W. S. du Dassels, of the Royal Mint, best known by the Diamond Jubilee medal of Queen Victoria and by his medal of Sir Gabriel Stokes, and Frank Bowcher (see Plate) by that of Thomas Huxley. These artists both cut their own dies when working in England in the manner of the French medalists, but with greater freedom than is the wont of the older school, has produced several examples of the art: the medals commemorative of the South African War and of Queen Victoria (two versions), all of 1900; and many portrait medals and plaquettes of small size have come from the same hand. Besides these, the leading English sculptors have produced a number of commemorative medals, such as those by Poynter, Hano Thornycroft, T. Brock, Onslow Ford, G. Frampton and Goscombe John; but, practising more continually in sculpture, they can claim only second place. Not that they sought to acquire that class of dexterity that constant habit alone can give. Alphonse Legros, who has cast a certain number of portrait medals, is usually included in the French school.

United States.—In the United States, the American medalists Augustus St Gaudens (see Plate) is perhaps the most prominent; but he is not, strictly speaking, a medalist, but a sculptor who can model in the flat. The chief names of F. Parker and W. O. Worthington (see Plate) are of some importance (see Plate) are of some importance. Some contributions to the medalist are by the French, but the work is often a travesty of the original design.

Although the striking of medals to commemorate important events is a practice of considerable antiquity, yet the custom of using the medal as a decoration, and especially as a decoration to do honour to those who have rendered service to the state

MEDAL

in time of war, is comparatively modern. It has been supposed that the circular ornaments on the Roman standards had medals in them which, but "there is a Medal of Gustavus Adolphus which was the case, and the standards shown on the column of Trajan appear only to have had plain bosses in their centres. It is true that the Chinese are said to have used military medals during the Han dynasty (1st century A.D.), but, as far as the West is concerned, we have to come to the 16th century before we find the custom of wearing medals as decorations of honour a recognized institution.

The wearing of decorative medals was common in England in the reign of Henry VIII., but the first medals commemorating a particular event that was decided more by special interest decoration, and were in all probability (though there is no absolute proof) bestowed as reward for military services rendered to the Crown, are the "Armed" medals of Queen Elizabeth, 1588-1589. Of these there are two. The earliest, generally styled the "Ark in flood" medal, is a large oval medal of silver (2 by 1-75 in.), and bears on the obverse a profile bust of the queen surrounded by the inscription, ELIZABETH D. G. ANGLIAE. F. ET H. REG. On the reverse is an ark on waves, with above the rays of the sun, and around the legend, SAEAS TRANQUILLA PER VNDAE. This medal dates from 1587, and it appears that there was given another medal, a little larger (2-3 by 2-1 in.) and struck in gold, silver and copper. The obverse of this second medal bore a full-face bust of Elizabeth, with the legend, characteristic both of the monarch and the period, DITIOR IN TOTO NON ALTER CIRCULUS ORBE. The reverse has an island around which ships are sailing and sea-monsters swimming, and on the island there are houses, a flourishing bay-tree, standing uninjured by a storm of wind, and lightning emerging from heavy clouds above. The island is inscribed NON IPSE PERICOVLA TANGVNT and the medal was minted in 1588. Here it may be noted that in following the history of medals as used as a decoration to reward military services, only those of British origin need be dealt with in detail, since Great Britain has utilized them in a much greater degree than any other nationality. The countless minor wars of the 19th century, waged by the forces of the Crown of every class, navy, army and auxiliary, have no equivalent in the history of other states, even in that of France, the United States and Russia. The great wars of the 19th century were divided by long intervals of peace, and the result is that with most of the great military powers the issue of campaign medals has been on a small scale, and in the main decorations have taken the form of "Orders" (see KnightHOOD and CHIVALRY: Orders), or purely personal decorations for some meritorious or exemplary service.

During the reign of Charles I. (1625-1649), we come across numerous medals and badges; a considerable number of these were undoubtedly associated with, and given, even systematically given, as rewards for war services; for a royal warrant "given at our Court of Oxford, the eighteenth day of May, 1648" which stated: "Sir William Parkhurst, Knight, and Thomas Bushell, Esquire, Wardens of our Mint, to provide from time to time certain Badges of silver, containing our Royal image, and that of our dearest son, Prince Charles, to be delivered to wear on the breast of every man who shall be certified under the hands of their Commanders-in-Chief to have done us faithful service in the Forlorn-hope." From the foregoing it must not be deduced that this medal was in any way intended to reward special valour. In those days forlorn-hopes were not volunteers for some desperate enterprise, as to-day, but a tactical advanced guard which naturally varied, both in numbers and arm of the service, according to ground and circumstances. That a very free distribution of the award was contemplated is evident from the fact that "soldiers" alone were specified as recipients and that a clause was inserted in the warrant strictly forbidding the sale of the medal. This letter ran:—

"And we do, therefore, most straitly command, that no soldier at any time do sell, nor any of our subjects presume to buy, or wear, any of these said Badges, other than they to whom we shall give the same, and that under such pain and punishment as our Council of War shall think fit to inflict, if any shall presume to offend against this our Royal command."

As there are in existence several medals of this period which bear the effigies of both the king and Prince Charles, it is uncertain which in particular was used for the "forlorn-hope" award. Very probably it is one, an oval silver-gilt medal (1-7 by 1-3 in.) which bears on the obverse a three-quarters (r.) bust of Charles I., and on the reverse a profile (l.) bust of Prince Charles (see Mayo, Medals and Decorations of the British Navy and Army, vol. 1, No. 16, Plate 5, No. 3). During the Commonwealth (1649-1660), parliament was lavish in the award of medals in recognition of war services, and for the first time we find statutory provision made for their bestowal as naval awards, in the shape of acts of parliament passed Feb. 22, 1648 and April 7, 1649 (cap. 12, 1648 and cap. 21, 1649), and Orders in Council of May 8 and Nov. 19 and 21, 1649, and Dec. 20, 1652. There is no doubt whatever that there was a "Medal of the Parliament" for sea service issued in 1649. This medal, oval (95 by 85 in.) and struck in gold and silver, had on the obverse an anchor, from the deck of which are suspended two shields, one bearing the cross of St George, and the other the Irish harp. The motto is MERVISTL. On the anchor stock, T. S. The reverse has on it the House of Commons with the Speaker in the chair. This medal is referred to in a minute of the Council of State of Nov. 15, 1649:—

"(5) That the Forms of the medals which are now brought in to be given to the several Mariners who have done good service this last Summer be approved off, viz: the Armes of the Crown on one side with M, and the picture of the House of Cofoms on the other."

There was a "Medal of the Parliament" for land service as well, is proved by the following extract from the Journals of the House of Commons (vii. 6, 7):—

"Resolved, That a Chain of Gold, with the Medal of the Parliament, to the Value of One Hundred Pounds, be sent to Colonel Mackworth, Governor of Shrewsbury, as a mark of the Parliament's Favour, and good acceptance of his fidelity: And that the Council of State do take care for the providing the same, and sending it forthwith."

This order was duly carried out, as is shown in the minutes of the Council of State, June 2 and July 30, 1652, but there is no trace to-day of either medal or chain. It is unlikley that this medal is one figured at page 117 of Evelyn's

Nunismoa (the engraving, unnumbered, is placed between Nos. 39 and 40, and there is no allusion to it in the text), which has on the obverse a representation of the parliament, and on the reverse a bust of the Protector with a camp and troops in the background.

The most splendid of all the naval awards of this period were those given for the three victories over the Dutch in 1653, namely:—

1 Thomas Simon, master and chief graver of the mint. Most of the medals of this period were his work, and they are considered to be amongst the best specimens of the medallic art that have been produced in the country.
MEDAL

1. The fight of Feb. 18/20, when Blake, Deane and Monk defeated Van Tromp and De Ruyter, the battle beginning off Portland and ending near Calais; (2) the fight of June 2 and 3, off the Essex coast, when Monk, Deane (killed), Penn and Blake, again defeated Van Tromp and De Ruyter; (3) the fight of 31st of July off the Texel, in which Monk, Penn and Lawson beat Van Tromp in what was the decisive action of the war. The authorization for these awards will be found recorded in the Journals of the House of Commons (vii. 296, 297), under date Aug. 8, 1653. The medals, all oval, and in gold, were given in three sizes, as described below:

A (2½ by 2 in.). Only four of these medals were issued, to Admirals Blake and Monk, each with a gold chain of the value of £100, and to Vice-Admiral Penn and Rear-Admiral Lawson, each with a gold chain of the value of £100. On the obverse is an anchor, from the stock of which are suspended three shields, bearing respectively St George’s cross, the saltire of St Andrew, and the Irish harp, the whole encircled by the cable of the anchor. On the reverse is depicted a naval battle with, in the foreground, a sinking ship. Both obverse and reverse have broad, and very handsome, borders of naval trophies, and on the obverse side this border has imposed upon it the arms of Holland and Zeeland. These four medals three are known to be in existence. One, lent by the warden and fellows of Wadham College, Oxford (Blake, it may be noted, was a member of Wadham College) was exhibited at the Royal Naval Exhibition of 1891. A second is in the royal collection at Windsor Castle. The third, with its chain, is in the possession of the family of Stuart of Tempفس House, Bedfordshire. This latter medal is known to have been the one given to Vice-Admiral Penn, an ancestor of the Stuart family. The one at Windsor is presumably Blake’s, as Tancred states “the medal given to Blake was purchased for William IV. at the price of 150 guineas (Tancred, Historical Records of Medals, p. 30). The medal at Wadham was formerly in Captain Hamilton’s collection. He purchased it at a low figure, but secrecy was kept as to the owner, and the original chain that was with it went into the melting-pot: there is therefore nothing to show whether it was Monk’s or Lawson’s, as the chain would have done. It was sold at Sotheby’s in May 1882 for £305.

B (2 by 1½ in.). Four of these medals were issued, each with a gold chain of the value of £40, to the “Flag Officers,” i.e. to the flag captains who commanded the four flag-ships. The obverse and reverse of this medal are, with the exception of the borders, precisely as in (A). The borders on both sides are a little narrower than those of (A), and of laurel instead of trophies. One of these medals—that given to Captain William Haddock, who was probably Monk’s flag-captain in the “Vanguard,” in the February fight, as he had been in that ship in the previous year, and who commanded the “Hannibal” (44) in the June battle—is now (1900) in the possession of Mr C. D. Holworthy, who is maternally descended from Captain Haddock.

C (1½ by 1¼ in.). This medal is precisely the same as (B), but has no border of any kind, and also was issued without the gold chains. It was in all probability one that was issued in lieu of numbers to the captains and other senior officers of the fleet.

Some of these medals have in the plate of the reverse an inscription: FOR EMINENT SERVICE IN SAVING Y TRIUMPH FIERED IN FIGHT WH Y DVCH IN JULY 1653. The medal so inscribed was given only to those who served in the “Triumph,” and commemorates a special service. Blake, incapacitated by wounds received in the fight of February, took no part in this action, but his historic flag-ship, the “Triumph,” formed part of the fleet, and early in the battle was engaged by the Dutch. The crew threw themselves overboard in a panic, but those who remained on board succeeded by the most indomitable and heroic efforts in subduing the flames, and so saving the vessel.

But undoubtedly the most interesting of all the medals of the Commonwealth period, is that known as the “Dunbar Medal,” authorized by parliament, Sept. 10, 1650, in a resolution of which the following is an extract:

“Ordered, that it be referred to the Committee of the Army, to consider what Medals may be prepared, both for Officers and Soldiers, that were in this Service in Scotland; and set the Proportions and Value of them, and their number; and present the Estimate of them to the House of Commons, (A.D. 1650.)

So came into being, what, in a degree, may be regarded as the prototype of the ‘war medal’ as we know it to-day, for the ‘Dunbar Medal’ is the very earliest that we know was issued to all ranks alike, to the humblest soldiers as well as to the commander-in-chief. It differed however in one very material point from the war medal of to-day—in that it was issued in two sizes, and in several different metals. There is no evidence to show what was the method that governed the issue of this medal; but the medal itself undoubtedly varied in size or metal, or both, according to the rank of the recipient. Of the two sizes in which the medal was issued the smaller, 1 by .85 in. was apparently intended for seniors in the respective grades, for it was struck in gold, silver and copper. The larger, 1·35 by 1·15 in. was struck in silver, copper and lead (see Mayo, op. cit. i. 20–21).

On the obverse of both issues of the “Dunbar Medal” is a left profile bust of Oliver Cromwell, with, in the distance, a battle. The reverse of the larger medal has the parliament assembled in one House with the Speaker; and, on the left, a member standing addressing the chair. The reverse of the smaller medal is the same as that of the larger, except that the member addressing the House is omitted. Cromwell himself expressed a wish to the “Committee of the Army, at London,” in a letter dated the 4th of February 1650/51, that his likeness, to procure which accurately the committee had sent Mr Simon to Scotland, should not appear on the medal. He writes:

“If my poor opinion may not be rejected by you, I have to offer to you which I think the most noble end, to wit, The Commemoration of Mr. Vic. Cromwell, and the Gratuity to the Army, which might be better expressed upon the Medal, by engraving, as on the one side the Parliament which I hear was intended and will do singularly well; so on the other side an Army, with this inscription over the head of it, The Lord of Hosts which was our Word that day. Wherefore, if I may beg it as a favour from you, I most earnestly beseech you, if I may do it without offence, that it may be so. And if you think not fit to have it as I offer, you may alter it as you see cause; only I do think I may truly say, it will be very thankfully acknowledged by me, if you will spare the having my Effigies in it.”

In spite of this request Cromwell’s “Effigies” is made the prominent feature of the obverse of the medal, to which the representation of the “Army” is entirely subordinated. His wish that the “word” for the day should be commemorated in, however, observed in the legend on the obverse, as is also, on the reverse, his suggestion that on one side of the medal there should be a representation of the parliament.

During the reign of Charles II. the issue of medals was numerous, and though we have it on the authority of Evelyn that many of these were bestowed as “gratuities of respect,” yet many were given as naval awards; and, for the first time, there appears official authorization for the confering of particular awards on those who had succeeded in the very hazardous service of destroying an enemy’s vessel by the use of fire-ships. In these we read the earliest “ Fighting Instructions” issued—those of Sir William Penn, in 1653, and again in an abridged form in 1655—no allusion to these awards is made, but that the custom of rewarding this special service prevailed, there is a piece of strong indirect evidence to show, in the shape of an amusing letter from a certain Captain Cranwill, of “ye Hare Pinke,” to the Admiralty Committee, dated Feb. 4, 1655—

An excellent reproduction of this medal, both obverse and reverse, is given in Plate 8, figs. 4 and 5, of the same work, and on Plate 9 will be found equally well reproduced facsimiles of the three different “Vic. Cresci art. 1653,” figs. 1, 2 and 3 and of the “Medal of the Parliament, for Sea Service, 1649,” fig. 1.
MEDAL

As for ye Pay yor Honrs were please to order mee for my service in ye Hare Pinn, I have most hearty thankes, and am ready to serve yor Honrs and my Country for ye future.

For though ye Hare be mewed in ye sand yet Cranwell at your mercy still doth stand.

A fire Ship now doth hee Crave,
And the Fox fain would he Have,
then has hee had both Fox and Hare,
then Spanish Admirall stand you cleare,
For Cranwell means ye Chaine of good to ware;
Sett penn to paper it is done,
for Cranwell still will be your man.

all of which goes to show that it had not been unusual to bestow gold chains, with or without medals, on the captains of fire-ships. By the “Fighting Instructions” issued 20th of April, 1665, by James, duke of York, lord high admiral, it was provided as follows. In the case of the destruction of an enemy’s vessel of forty guns or more, each person remaining on board the fire-ship till the service was performed was to receive £10, “on board ye Admirall immediately after ye service done,” and the captain a gold medal and “shuthe other future encouragement by preferment and commande as shall be fitt both to reward him and induce others to perform ye like Service.”

If it was a flag-ship that was fired “ye Recompense in money shall be doubled to each man performing it, and ye medall to yshuthe probably others shall particularly express ye Eminensye of ye Service, and his with ye other officers preferement shallbe suitable to ye merit of it.” This was followed by an “Order of the King in Council” dated Whitehall 12th of January 1666-1670, in which the lord high admiral is authorized “to distribute a Medall and Chaine to such Captaines of Fire Shipps as in the last Dutch Warr have burnt any Man of Warr, as also to any of them that shall perform any such service in the present Warr with Algiers. Which Medals and Chains are to be of the price of Thirty Pounds each or the Office of a Judas.”

To complete the story of fire-ship awards, it may here be noted (though out of chronological order) that in 1793 revised “Fighting Instructions” were issued by Admiral Sir George Rooke, in which it was provided that the captain was to have his choice between a gratuity of £100, or a gold medal and chain of that value. Lastly an order of the king in council, dated St James’s, 16th of December, 1742, ordered that all lieutenants of fire-ships (which originally carried no officers of this rank) should be entitled to a gratuity of £50 “in all cases where the Captain is entitled to the Reward of £100.”

Though probably others were conferred, so thorough an investigator as the late John Horsley Mayo, for many years assistant military secretary at the India office, who had special opportunities of access to official records, traced but three authenticated fire-ship awards. Those were: (1) to Captain John Guy, who blew up his fire-ship the “Vauvius” under the walls of St Malo in 1693; (2) to Captain Smith Callis who, with his fire-ship the “Duke,” in 1742, destroyed five Spanish galleys which had put into St Tropez, to the eastward of Marseilles; (3) to Captain James Woodridge, who commanded the British fire-ships in Aix Rose on the 11th of April 1809, when the French sail of the line were burnt. This latter is believed to be the last award of the kind that was issued. Fire-ships awards are of special interest as affording a precedent, in future naval wars, for the award of special decorations for torpedo services.

It is in this reign also that we first find a case of medals being granted by the Honourable East India Company. The earliest of these would appear to have been a gold medal of the value of £20, conferred on Sir George Oxinden, president at Surat, 1622-1669, in 1668, for considerable civil and military services. Surat was then and until 1687, when Bombay took its place, the seat of government of the Western Presidency, and the most eminent of Sir George’s services was the defence of the Company’s treasures and possessions at that place against Sivajee and the Maharrattas in 1664. It is not known what has become of this medal, but there is indirect evidence to show that it was a circular medal, three inches in diameter. On the obverse the “Arms of the Governor and Company of Merchants of London trading to the East Indies, with crest, supporters, and mottoes,” and around the legend NON MINOR EST VIRTVS QUAM QVÆRERE PARTA OERI. On the reverse was probably blank to admit of an inscription. This award was the forerunner of many given by the H. E. I. Co., several of which were “general distributions” of the very highest interest, which will be dealt with together later on.

The awards made in the reigns of James II, William and Mary, William III., Anne, George I, George II., may be very briefly dealt with. Almost without an exception they were either naval or conferred by the Hon. East India Company, and with only perhaps one or two exceptions, they were “personal” as distinct from “general” awards. Of the very few medals awarded by James II., one was an undoubted military award, though curiously enough the recipient was a bishop. This was Peter Mew, who had been made bishop of Bath and Wells in 1672, was translated to Winchester 1684, “and next year was commanded by the king, in compliance with the request of the gentry of Somerset, to go against Monmouth, and did eminent service at the battle of Sedgemoor, where he managed the artillery; for which he was rewarded with a rich medal” (Hutchins’s History of Dorset, 3rd ed., vol. iv. p. 149). It is, however, the first case of an “ordinary” of a medal during the reigns under review. In the cases of the medals struck after the battle of La Hogue, 1692, and Culloden, 1746. By an act of parliament passed in 1692 (4 Gul. and Mar. c. 25), it was enacted that a tenth part of the prize money taken by the navy should be set apart “for Medals and other Rewards for Officers, Mariners, and Seamen in their Majesties Service at Sea who shall be found to have done any signal or extraordinary service.” (Later a Royal Declaration of Queen Anne, the 1st of June 1702, provided that “medals in gold and silver medals were also paid out of Her Majesty’s Shares of Prizes.”) This is the first case in naval records authorizing the issue of medals to men as well as officers, and the conferring of the “La Hogue” medal was the first case in which the enactment was carried into effect, at any rate as far as admirals and officers are concerned. Seamen and soldiers had a more substantial reward, for the queen sent £10,000 to be distributed amongst them, whilst gold and silver medals were struck for the admirals and officers. The medal, which was circular, 1.75 in. in diameter, had on the obverse the busts conjoined of William and Mary, r., with around GVL ET MAR D G MB FETH REX ET REGINA. This medal was a representation of the fight, showing the French flag-ship, “Le Soleil Royal,” in flames, with above the legend, NOX NVLLA SECVTIA EST, and, in the exergue, PVGN NAV INT ANG ET FR 21 MAY 1692.

As regards the medal struck after Culloden, fought on the 16th of April 1746, and in which the adherents of the young Pretender were completely routed, there is nothing even to show that it was issued even by the authority of the government, though it was undoubtedly worn, and (if a contemporary portrait is to be relied upon, that of an ancestor of Mr W. Chandos-Pope of Radbourne Hall in Derbyshire) around the neck attached to a crimson ribbon with a green edge. There is no doubt it was struck in gold, silver and copper, but how it was awarded there is no proof, probably only to officers. The obverse had an r., bust of the duke of Cumberland, with above CUMBERLAND, below YEO f (Richard Yeo fecit), and, on the reverse, an Apollo, laureate, leaning upon his bow and pointing to a dragon wounded by his arrow. The reverse legend was ACTUM EST ILICET PERIT, and, in the exergue PROEL COLOD AP XVI MDCCCLVI. The medal is a strikingly handsome one, with an ornamental border and ring for suspension, oval, 1.75 by 1.45 in., but very few specimens are known to exist. Those in gold were probably only given to officers commanding regiments and a very fine specimen of these, originally conferred on Brigadier-General Fleming (at one time in command of the 36th Foot) is now in the collection of Major-General Lord
MEDAL

Cheylesmore. In his monograph, Naval and Military Medals, Lord Cheylesmore mentions another "Culloden" medal in his collection, "a slightly larger one in white metal, which leads one to suppose that it was given in inferior metal to the more junior branches, probably officers; but whether this was the case or not I am unable authoritatively to state." However, one thing is fairly certain, that the issue of the "Culloden" medal was no sense "general," as we now understand the term, nor as were the issues for the "Dartmouth" medal, but a Holland and Brazil Company which will next be dealt with.

No medal awards were made to either the naval or military services for the Seven Years' War, and the American War of Independence. In fact George III. had been more than thirty years on the throne when the first medal award by the Crown was given, in the shape of the navy gold medals, first issued in 1794. It will however be more convenient to deal later with these medals and the army gold medals and crosses given for services in the long and arduous struggle of 1793-1815, and to describe here in sequence those medals which were issued by the Honourable East India Company, the issue of which was with certain limitations, "general," thus reverting to the precedent first established in the "Dunbar" award, namely an issue to all ranks. They are nine in number, and are described below in the chronological order of the military operations for which they were awarded.

1. The "DECCAN" medal. Authorized, first in 1784, and again in 1785. Obverse: Figure of Britannia seated on a military trophy, with her right hand holding a wreath of laurel and extended towards a fortress over which flies the British flag. Reverse: Persia in script. Inscription: "DECCAN Medall". Obverse: A wreath added, in memory of good service and intrepid valor. A.D. 1784, A.H. 1199; round. "Like this coin may it endure in the world, and the exertions of those lion-hearted Englishmen of great name, victims from Hindostan to the Deccan, become exalted." This medal was issued in two sizes, diameters 1-6 and 1-25 in. The larger medal was struck both in gold and silver, the smaller in silver only, and both medals were struck without a year. A year, however, can be added to the medal. A smaller medal was awarded to two large detachments of the Bengal army, denominated the "Bombay Detachment," (authorized 1784), and the "Carnatic Detachment," (authorized 1786), which respectively fought in the west of India and Guzerat, 1778-84, and in the south of India, 1780-84. The medal was not given to any Europeans, only to natives; the larger medal in gold to Subadaras, and in silver to Sepoys, and the smaller in silver to non-commissioned officers and sepoys. By a minute of council, dated the 15th of July, 1784, a further boon was granted to the "Bombay Detachment," inasmuch as it was determined that all members of that detachment, and of the troops engaged in the Carnatic, should be entitled to the duties levied by the authorities on pilgrims to Coya in Behar. As the large majority of the troops were high caste Hindus, and Coya was, and is the Mecca of Hindustan, this favour must have been much appreciated by the troops.

This medal is the earliest Anglo-Indian example of a medal issued alike to all ranks.

2. The "MYSORE" medal. Authorized, 1793. Obverse: A sepoy holding in his right hand the British colours, in his left an enemy's standard reversed, whilst his left foot rests on a dismantled cannon. A fortified town is in the background. Reverse: Within a wreath; "For Services in Mysore. A.D. 1791-1792. Between which years and in an inscription in Persian: "A memorial of devoted services to the English government at the war of Mysore. Christian Era, 1791-1792, equivalent to the Mahomedan Era, 1205-1206." Like the "Mysore" this medal was in two sizes, diameters 1 7 in. and 1 25 in., struck both in gold and silver only, and both were worn suspended from the neck by a yellow cord. The medal was awarded for the operations against Tipoo Sultan, and was bestowed on the officers and men of the Infantry of the Foot and Cavalry, and on the Artillery Lascars, who either marched by land, or proceeded by sea to the Carnatic and returned to Bengal. The large gold medals were given to Subadaras, the large silver to "Jamadars and Seprangs," the small silver medals to "Havildars, Naiks, Tinads, Sepryoys and Lascars." The award therefore, took proceded precisely the precedent set in the "Carnatic" medal. The gold medals were large in size, and there was a collection of Captain Whitaker, late 4th Fusiliers, whose collection, and that of Lord Chelmsford, are probably the two finest that have as yet been brought together.

Lord Chelmsford. Authorized, 1807. Obverse: An English inscription: "For Services on the Island of Ceylon. A.D. 1795-6." Reverse: A Persian inscription: "This Medal was presented to the best good soldiers in the Army in the year of the Hegira 1209-10." This medal was issued in only one size, 2 in. diameter, and was awarded to a small force of Bengal native artillery which formed a fraction of a large body of British and native troops (the rest did not receive the medal) which captured Ceylon from the Dutch in 1795-96. It is the only instance of a war medal that has merely a verbal design on both obverse and reverse, and moreover it was not struck in gold, but only in silver. The precaution was taken in that it only was granted twelve years after the services that had earned it had been rendered. Only 123 medals were struck, 2 in gold for native officers, and 121 in silver for other ranks. Like the above, but so preceding, it was worn from the neck suspended from a yellow cord.

4. The "SERINGAPATAM" medal. Authorized, 1799, for services in Lord Harris's campaign of that year, and the storm of Seringapatam on 4th May, 1799. Obverse: "A lion overcoming a tiger, the emblem of Tipoo Sultan." Above is a standard, with, in the innermost part of the hoist immediately contiguous to the staff, the Union badge, and, in the fly, an eagle, with the motto "Seringapatam." Reverse: In the exergue: IV. MAY, MDCCXCIX. (the date of the assault). It was in one size, 1-9 in. but of five different kinds. Although the medal was authorized in 1799, it was not issued before order for the preparation of 30 gold medals, 185 silver-gilt, 820 silver, 5000 copper bronzed, and 45,000 pure tin, were given, the artist being C. H. Kechler, and the medals made by Matthew Bolton at the Soho Mint. The gold medals were given to officers, in silver-gilt to field officers, in silver to captains and subalterns, in copper bronzed to non-commissioned officers, and in pure grain tin to privates and sepoys. With regard to this medal there is an incident that is worth recording. The bulk of the troops engaged at Seringapatam were Crown forces, or belonged to the Madras and Bombay presidencies; the only Bengal troops taking part being five battalions of infantry, and artillery detachments. On their return to Bengal no steps were taken with regard to medals till 1807, when medals copied from the Soho Mint one, 1-8 in. only in diameter, were made at the Calcutta Mint. Following the Bengal example, the British officers and men were given medals, but the medals were struck in gold for officers, and in silver for the other ranks. A Bengal native officer therefore wore just the same medal as a general officer of any of the other forces, and similarly a Bengal sepoy wore the same medal as a British captain or subaltern of the Crown. The Bengal medal can easily be distinguished from the others, for in the reverse the artist's initials C.H.K. are inscribed. "C.M.H. Some officers, amongst the Lord Harris himself and his second-in-command, David Baird, wore the medal with the red, blue-bordered ribbon, which is the same as that worn with the Army Gold Medal (see below) and was also adopted for the Bengal troops, both of which were to be passed over into the new medal, although no ribbon was issued with the medal, recipients were given to understand that the ribbon would be of a deep maize colour and watered, the shading on the ribbon symbolizing the stripes in the fur. This being the case, the "C.M.H. This medal, of Wellington's (silver gilt), has the maize (or yellow as it is often termed) ribbon, and the medal was undoubtedly more generally worn with this ribbon than with the red ribbon. The medals also apparently occasional instances of it having been worn with a plain red ribbon.

5. The "EGYPT" medal. Authorized, 1801. Obverse: A sepoy holding the Union Flag in his right hand; in the background a camp. In exergue, in Persian: "This medal has been presented in commemoration of the defeat of the French Army in Egypt by the Britannicks under the command of Lord Cornwallis, 1801." In English below: They came out to India for distribution, and it was not till 1815 that the Company's European officers had the prince regent's sanction to wearing them on public occasions. For the first time the issue was absolutely "general," to the officers and men of the Crown and Company services of the H.E.I. Co., but it was not till 1851, when the First India G.S. Medal was awarded, that official sanction was given to their being worn. The medal was given to officers, in silver-gilt to field officers, in silver to captains and subalterns, in copper bronzed to non-commissioned officers, and in pure grain tin to privates and sepoys. The medals were struck both in gold and silver, and medals struck in bronze were issued to the Persian officers, and a smaller medal struck in brass and copper was given to the sepoy and native officers and men.

For services in the expedition to the coast of Egypt, in the following year, 1802, and four pyramids. In the exergue, MDCCCII. This medal was also awarded to native officers and men of the small force of Bengal troops that co-operated in Sir Ralph Abercromby's descent on Egypt in 1801 (see Baird, Sir David). This was another case of a belated issue (1811) for the Bengal troops and two years later for the Bombay troops.

For the expedition to the coast of Egypt, 1801, the Bengal troops 776 medals were struck, 16 in gold for commissioned officers, 760 in silver for other ranks. The Bombay troops 974 medals were struck, 20 in gold for commissioned officers, 954 silver medals for the issue of the medal to their troops in 1803, but apparently did nothing till 1812, when they were asked the Calcutta Mint for a copy of the medal to enable them to prepare similar ones. The Bombay Mint to whom the request was made, had not how made a design for the medal, but for the sample was returned to Calcutta with the request that 1439 medals might be struck there. This was accordingly done, but all medals were struck in silver, and with the result that there were 632 Bombay troops in all ranks alike. As in the case of the "Deccan" medal, Hindu sepoys, who had volunteered for Egypt, were exempted from the duties levied on pilgrims. This medal was worn suspended from the neck by a yellow cord.

6 MEDAL
### Wars of the French Revolution and Napoleon Eras

- **Navy Gold Medal, 1794.** 1794-1815.
- **Army Gold Medal and Cross, 1810.** 1808-14.
- **Waterloo, 1815.** 1815.
- **Navy General Service, 1848.** 1793-1848. Medal dated 1848 but authorized 1847. Enquiries date 1793-1814. Last operations for which awarded took place 1811.
- **Army General Service, 1848.** 1793-1814. Medal dated 1846 but authorized 1847.

### India. Awards by the Hon. East India Company

- **Seringapatam, 1801.** 1799.
- **Gazni, 1841.** 1839. Shah Soolah's original award of 1839 was after his death, carried out by H. E. I. Co., in 1841.
- **Sutlej, 1845.** 1845-46.
- **Punjab, 1849.** 1840-49.

### India. Awards by the Crown

- **First India G.S., 1851.** 1799-1826. Date given is in exergue, but the first action for which the Medal was awarded did not take place until 1803. This Medal is often termed "Army of India" Medal.
- **Second India G.S., 1854.** 1852-1855.
- **Indian Mutiny, 1858.** 1857-58.
- **Afghanistan, 1879.** 1878-80. Second Afghan War.
- **Third India G.S., 1895.** Since 1895. The award of March 1903 made the 7th Clasp.
- **China, 1842.** 1841-42, 1857-60, 1900.
- **Crimea, 1854.** 1854-56.
- **Turkish Crimea, 1855.** 1854-56.
- **Baltic, 1866.** 1854-55.
- **New Zealand, 1869.** 1845-47, 1860-66.

### Russian War

- **China, 1842.** 1841-42, 1857-60, 1900.
- **Crimea, 1854.** 1854-56.
- **Turkish Crimea, 1855.** 1854-56.
- **Baltic, 1866.** 1854-55.
- **New Zealand, 1869.** 1845-47, 1860-66.

### Northern Africa

- **Abyssinia, 1868.** 1867-68.
- **Egypt, 1882.** 1882-89.
- **Khedive’s Star, 1883.** 1882-90.
- **Khedive’s Sudan, 1897.** 1896-98, and since.
- **Queen’s Sudan, 1899.** 1896-98.

**Note:** Date following Title is that of authorization of first award, those under Titles are the year, or years, in which the operations for which the Medal was awarded took place.
MEDAL

6. The "RODRIGUES, BOURBON AND MAURITIUS" medal. Authorized, 1811. Obverse: A sepoy, holding in his right hand the British flag, in his left a musket with bayonet fixed, stands with his left foot trampling a French eagle and standard; beside the figure is the name of the island. Within a wreath, in Persian: "This medal was conferred in commemoration of the bravery and devotion exhibited by the Sepoys of the English Company in the capture of the Islands of Rodrigues, Bourbon and Mauritius, in the year 1810. The names of the officers of the Bengal Presidency that formed part of the combined naval and military forces that effected the reduction of these islands in 1809–10. The government of Bengal also suggested for the consideration of the British government the institution of a circulating bronze and gold medals; the gold medals shall be conferred on the native troops from those Establishments;" but those governments do not appear to have complied with the suggestion, a distinct injustice to the Madras and Bombay troops employed. This medal was designed by Mr. Bowyer (now in the collection of Lord Cheylesmore). The medal, 1-in. in diameter, was struck in gold and silver, 45; gold for native officers, 2136 silver for all other ranks. The reverse was as customary in so many cases with yellow silk cord suspended from the neck.

7. The "JAVA" medal. Authorized, 1812. Obverse: A representation of the storming of Fort Cornelio. On a flag-staff the ensign of the fort is flown above the scene, and before it the word Cornelio. Reverse: In Persian: "This medal was conferred in commemoration of the bravery and courage exhibited by the Sepoys of the English Company in the capture of Java, 1228, Hegira, in the year 1824–26. AUGUST MDCCXCXI." This medal was awarded to the native troops of the Honourable East India Company (all Bengal), which had the distinction of taking the fort. Its obverse is in the names of the Medals of the General Officers of Admiral Lord Anson and Admiral Anson, which effected the capture of Java from the Dutch in 1811. The medal, 1-in. in diameter, was struck in gold and silver, 133 in the former metal for native officers, and 6590 in silver for all other ranks, and was worn in the usual manner with a yellow silk cord.

8. The "NEPAL" medal. Authorized, 1816. Obverse: Hills crowned with stockades. In right foreground the colours and banners of the allied forces, to the left the word Nepal, in Persian: "This Medal was conferred by the Nawab Governor-General Bahadur in testimony of the good, service, skill and intrepidity of the Sepoys of the Forts of the East India Company in the year 1229 and 1230." This was awarded to the native troops of the East India Company who took part in the arduous operations in Nepal in 1814–16. This medal, 2 in. in diameter, marks a very interesting new departure, for it was struck only in silver, and given to all ranks precisely alike, whether the recipient was commissioned or not. It was worn from the usual yellow silk cord.

9. The "BURMAH" medal. Authorized, 1826. Obverse: Representation of the storming of the great pagoda at Rangoon; on the left, a palm tree under which the general and staff, and the river with boats, are depicted; and on the right, an elephant and a steamer facing a hill joining in the attack. In exergue, in Persian: "The Standard of the Victorious Naval Action of England upon Ava." Reverse: The White Elephant of Burma crouching in submission before the British Lion; behind the Lion, the Sepoys, with the Fort of Ava; below the date, the plains of Ava, and drooping and between the two flags palm trees. In exergue, in Persian: "The elephant of Ava submits to the lion of England, year 1826." This, one of the most beautiful of all war medals, was designed by W. Danieli, R.A., and executed by W. Wyon; and was awarded to all the Company's native troops that participated in the First Burmese War, 1824–26. The medal, 1-5 in. in diameter, was issued in gold to native officers, in silver to other ranks. In all there were struck； for Bengal troops, 308 gold, 15,105 silver; and for Madras, 450 gold and 20,025 silver. Of the Madras medals however nearly half were still unclaimed in 1840. It is with this medal that the native troops of the East India Company have kept faith with the use of a ribbon, and the manner in which medals should be worn. In 1831, it was officially ordered that the colour should be red, with blue edges—it was in fact precisely similar to the Waterloo ribbon medals, which see Plate I.—and the regulations which governed the use of the medal: "be worn perfectly square upon the centre of the left breast, the upper edge of the ribbon being even with the first button for ranks, and the second button for ranks wearing coat Belts." Like the Waterloo medal it was mounted on a steel clip and ring, and the medals were struck at the Royal Mint instead of, as heretofore, in India.

This closes the list of the Indian medals, which, with the exception of that for Seringapatam, were issued only to the native troops of the Honourable East India Company. All are now very rare and very highly valued by collectors.

As has already been stated, the first war medals awarded by the Crown in the reign of George III., were the navy gold medals, instituted on the occasion of Lord Howe's great victory over the French fleet on the 1st of June 1794. On the 26th of that month the king and queen visited Portsmouth, and, on the deck of the "Queen Charlotte," Lord Howe's flag-ship, presented the victorious admiral with a diamond-hilted sword of the value of three thousand guineas. Gold chains, from which the medals were afterwards to be suspended, were also conferred on H.M. Lord Howe; Vices Admirals Graves and Sir Alexander Hood; Rear-Admirals Gardner, Bowyer and Pasley; and Captain of the Fleet Sir Roger Curtis. At the same time the king announced his intention of conferring gold medals on each of the officers named, and similar, but smaller medals on the captains. The medals were delivered in 1796, the Admiralty ordering "The Admirals to wear the Medal suspended by a ribbon round their necks. The Captains to wear the Medal suspended to a ribbon, but fastened through the third or fourth button-hole on the left side. The colour of the ribbon, which is white with broad blue borders (see Plate I.), did not of course supersede the gold chain in the case of those officers on whom chains had been conferred. They wore their chain with the ribbon, and the medal of Admiral Bowyer (now in the collection of Lord Cheylesmore) is so suspended. The same splendid and interesting medal was later conferred for various fleet and ship actions deemed worthy of special acknowledgment; and so came into being the first regulation medal for naval officers.

The two medals are, with but one slight distinction, identical in size; the larger being 2, and the smaller 1-3, in. in diameter. The design is—:

Obverse: The fore part of an antique galley, on the prow of which rests a figure of Victory who is placing a wreath on the head of Britannia who stands on the deck of the galley, her right foot resting upon a helmet, her left hand holding a spear. Behind Britannia is a "union" shield, charged with the Cross of St George and the Solute of St Andrew. (Ireland had not then been added to the Union.) Reverse: Within a wreath of oak and laurel, the name of the recipient, the event for which the medal was conferred, and the date. (In the smaller medal the wreath is omitted.)

In all, eighteen actions were recognized by this medal, the complete list of which is as follows:

The "Glorious First of June" (5 large and 18 small medals); St Vincent (5 large and 14 small medals); Cape St. Vincent (Oct. 11, 1797) (2 large, 15 small medals); The Nile (Aug. 1, 1798) (1 large and 14 small medals); Re-capture of the frigate "Hector" from the French (Jan. 1, 1798) (4 small medals); Capture of the frigate "Bac dou Zaffer" by H.M.S. "Seahorse" (July 6, 1808) (1 small medal); Capture of the French frigate "Theis" by H.M.S. "Sappho" (Aug. 25, 1809) (1 small medal); Capture of the French frigate "Furique" by H.M.S. "St. Vincent" June 6, 1809 (1 small medal); Capture of the Island of Bande Noire (Aug. 9, 1810) (1 small medal); Captain W. Howe's action off Bussaco (March 13, 1811) (4 small medals); Capture of the French 74-gun ship "Rivoli" by H.M.S. "Victorious" (Feb. 22, 1812) (1 small medal); The Chesapeake and "Shannon" (June 1, 1813) (1 large and 7 small medals); Capture of the French 30-gun ship "Hebrus" (March 27, 1814) (1 small medal); Capture of the American frigate "President" by H.M.S. "Endymion" (Jan. 15, 1814) (1 small medal).

In all 22 large medals, and 117 small, were awarded; but this does not say that all who were entitled to the medal received it. This is most notably the case with regard to the "Glorious First of June." To the exclusion of all others the first medal was awarded to those flag officers who had received gold chains, and to such captains as were specially mentioned in Lord Howe's dispatch of the 21st of June, despite the fact that the admirals specially put it on record that they had no intention of conferring medals on them. The disadvantage of the other commanders, who may have been equally valuable to the victory, was not compensated for by the grant of a medal of any kind.
deserving of the approbation of the Lords Commissioners of the Admiralty, although I am not enabled to make a particular state-ment of the conclusion of this report; the only difference between this and the former, is that the gold medal was awarded to Rear-Admiral B. Caldwell, fifth in command on the great day, to his flag-captain, Captain G. B. Westcott, and to seven other captains of line of battle ships engaged. One captain however, who was not numbered among the preceding, was formerly making the tour de force eminently characteristic of the superb breed of naval officers that the great wars had brought into being. This was Captain Samuel Boulton, flag-captain of the FRIGATE TRAFALGAR. When Collingwood was awarded the medal for St. Vincent, where he commanded the “Excellent,” he flatly refused to receive it unless that for the First of June was also conferred upon him, which was done. While the Nile was running, and the Trafalgar, all these three captains received the medal. At the Nile, Troubridge’s ship, the “Culloden,” grounded in entering the bay, and so, strictly speaking, he was not engaged in the action; but the proceedings included him in the award, so for his services both before and since, and for the great and wonderful exertions he made at the time of the action, in saving and getting off his ship.

For Camperdown, one captain, afterwards found guilty by court-martial of failure in duty, did not receive the medal. Several posthumous awards of the smaller medals were made to the relatives of officers who were either killed in action or died of wounds. These were: on the first of June, Captains Hutt (“Queen”), Montagu (“Montagu”), Harvey (“Brunswick”); at Camperdown, Captain Burgess (“Arden”); at the Nile, Captain Westcott (“Majestic”); and the Trafalgar, Captain Boulton (“Darwin”), and Captain Westcott was doubly unfortunate, for he was one of the First of June captains who should have received the medal but did not. Captain Miller of the “Theseus” also did not receive his medal for the same reason. Boulton, he was told, was killed in an accidental explosion the May following, the medal arriving after his death, and being returned to the Admiralty. In only a few cases of awards of smaller medals to officers below flagrank, these being Sir R. Curtis, captain of the fleet to Lord Howe on the First of June, and Nelson, who only flew a commodore’s broad pendant at St. Vincent, following this latter precedent Sir R. Strachan should have had the large medal for the action of the 4th of November 1805, for he also was a commodore, but it was denied him for what seems quite an inadequate reason, namely that he was junior in rank to Captain Hervey of the Tenedreuse, who was the senior commodore on that day.

The first of June was conferred on only three cases on officers below the rank of post captain. These were Commander Mounsey of the “Bonne Citoyenne,” for the capture of the “Furieux” and Lieuts. Phillot and Stockham, who at Trafalgar commanded respectively the “Ajax” and the “Thunderer.” the captains of two ships being at the time of the action in England giving evidence at the court-martial of Sir Robert Calder. In all, of the eighteen awards of the large medal, and Medal, eight were for flagships, which were between squadrions of frigates, seven for single ship actions, one between line of battleships, six in which frigates were engaged, two for shore operations (in both cases the taking of islands for the safety of the fleet), and one for the capture of the “Eve of the “Surprise.” This last mentioned award is one particularly memorable, not only because it was the first time that the medal was awarded to a captain, but also because in the case in which the medal was awarded for boat service pure and simple.

Nelson’s two great victories, the Nile and Trafalgar, also earned a medal for all ranks that participated in them, but these awards were not made by the Crown but by the generosity of two private individuals, though of course with the king’s approval and permission. The first of these is “Davison’s Nile Medal,” which Mr Alexander Davison, Nelson’s prize agent and a valued friend, came to be struck at a cost of near £2000, and one of which was presented to every officer and man engaged at the Nile. The medal, 1.85 in. in diameter, was given in gold to Nelson and his captains, in silver to the commodored officers, and the supplementary medals to warrant and petty officers, in copper bronze to seamen and marines.

Obverse: Hope, standing on a rock in the sea, holding in her right hand an olive branch, and supporting with her left side a shield on which is the bust of Nelson surrounded by the legend: “EUROPE’S HOPE AND BRITAIN’S GLORY.” Behind the figure are the ship’s anchors. Inscription below: “REAR-ADMIRAL LORD NELSON OF THE NILE.”

Reverse: The French fleet at anchor in Aboukir Bay, the British fleet advancing to their attack; a setting sun denotes the time of the action. Across the top: “ALMIGHTY GOD BLESS THE FRUITS OF OUR ARMS”; and, in exergue: “VICTORY OF THE NILE AUGUST 1 1798.” In the reverse the engraver when sinking the die forgot to put the date on these medals; in consequence of the delay in striking the medals in the east instead of in the west, and the land which is shown on the right should properly be on the left.

Davison’s Nile medal was struck at the Soho Mint, Birmingham, by Boulton, and it was this that probably inspired the latter to present a medal to all who took part in the battle of Trafalgar.

Boulton’s Trafalgar Medal” was 1.9 in. in diameter, and given in gold to the three admirals, in silver to captains and first-lieutenants, and in copper bronze to the lieuts. and ensigns of the ships. When the medal was awarded, one of the recipients being disgusted at what they deemed the paltriness of the medal, the reverse was engraved: “HER MAJESTY’S MEDITERRANEAN FLEET. OCTR. 21 1805.”

Both the Davison and the Boulton medals were worn suspended from a blue ribbon. These are the only two cases in which officers and men of the navy and army have accepted and worn medals presented by a private individual.

The Gold Medal given by George III. to the superior officers in command at the battle of Maida, in Sicily, on the 4th of July 1806, is an award of special interest, for not only was it the first military award made by the Crown during the reign, but it was moreover the prototype of the superb army gold medals and crosses which were so widely distributed during the years that followed. A general order of the duke of York, commander-in-chief, dated Horse Guards, 22nd of Feb. 1808, awarded a gold medal for Maida to Sir John Stuart, K.B., his three brigadiers, and nine other officers. Subsequently four other officers received it, so in all seventeen officers received the award.

It was prescribed that the medal should be worn suspended by a ribbon of the colour of the Sash, with a blue edge, from a button of the coat on the left side.” It was in fact to be worn in the same way as the small Navy Gold Medal, and as this grant established blue and white as the specific navy ribbon, so did the Maida award establish red with a blue border as the regulation military ribbon. The Maida ribbon is in fact precisely the same as the Waterloo ribbon shown in Plate I. The Maida medal was 1.5 in. in diameter and struck in gold only. It was issued precisely alike, quite irrespective of rank, to each of its seventeen recipients.

Obverse: Head of George III., laureted and facing left, with below the legend: GEORGIVS TERTIUS REX. Reverse: Britannia casting a spear with her right hand, and on her left arm the Union shield, above, and approaching her is a Flying Victory holding out a wreath. In front of Britannia in four lines, is MAI/DA/IVL IV/MDCCCCVI/; behind her the triquetra or trinacria, the symbol of the island of Sicily. In the exergue, the original cross-pointer.

Two and a half years after the Maida award the king authorized the “Army Gold Medal,” the first grant of which was notified by the commander-in-chief, in a Horse Guards general order dated the 9th of September 1810. This authorized the bestowal of the medal on 107 senior officers mentioned by name. The battles commemorated were Roliça, Vimiera (1808), the cavalry actions of Sahagun and Benevente (1808), Corunna and Talavera (1809). The Army Gold Medal so awarded was in two sizes, large, 2.1 in. in diameter, for general officers, small, 1.5 in. in diameter, for officers of lower rank: and the regulations provided that it should be worn from a red ribbon edged with blue, the larger round the neck, the smaller on the left breast from a button-hole of the uniform. The ribbon was the same width, 1/2 for both ribbons, and precisely the same later on for the Gold Cross. Both large and small medals were of identical design, in fact there was no difference, either in medals or in ribbons, except in size and the style in which they were worn.

Obverse: Britannia seated on a globe, holding in her right hand a laurel wreath, and in her left, which rests upon a Union shield depicting the arms of the Austrians. A bust of Lord Nelson in uniform with the word, also in a large lower case, arms of the order of St. George. Reverse: A wreath of laurel, encircling the name of the battle or operations for which the medal was granted.

In the following years subsequent orders similar to the original grant extended the award of the Army Gold Medal, until eventually twenty-four distinct awards were made, commemorating twenty-six actions, or series of operations, which took place, and medals of almost every description of the Peninsula, but also in North America, and both the East and the West Indies.

The Peninsula medals were for Roleia and Vimiera, Sahagun and Benevente, Corunna, Talavera, Busaco, Barrosa, Fuentes d’Onor, Albuera, Ciudad Rodrigo (1812), Badajoz (1812),
Salamanca, Vittoria, Pyrenees, St Sebastian, Nivelle, Nile, Orthes, Toulouse. The West Indies medals were for Martinique (Feb. 1809) and Guadeloupe (Jan.–Feb. 1810), the North American for Fort Detroit (Aug. 16, 1812), Chateauguay (Oct. 26, 1813) and Yorktown (Sept. 17, 1813), and there was lastly, a medal awarded for Java (Aug.–Sept. 1814).

From the above it will be seen that as time went on many officers became entitled to two, three and even more medals, and as this was found inconvenient, the method of granting the award was very materially amended as notified by the commander-in-chief, in a general order, dated Horse Guards, October 7, 1813. This order formulated regulations which were as follows:

1. That one medal only was to be borne by each officer recommended for the distinction.
2. That for a second and a third action a gold clasp was to be attached to the ribbon from which the medal was suspended inscribed with the name of the action.
3. When a fourth distinction was earned, the medal and two clasps were to be replaced by a Gold Cross having the four actions for which it was awarded inscribed upon it, one upon each arm.

On every occasion the recipient was awarded the decoration after the fourth a Gold Clasp worn on the riband was added to the Cross.

The regulations further laid down that only officers should be recommended who had been "personally and particularly engaged" on the occasion, and that officers were to be named by "special selection and report of the Commander of the Forces upon the spot, as having merited the distinction by conspicuous conduct, whether at the front or in the rear." On the whole this was restricted in his selection to General Officers, C.Os. of Brigades, C.Os. of Artillery or Engineers, and certain staff officers holding field rank, and Commanding Officers of Units, and Officers succeeding to such command during an engagement.¹

It was also ordered that awards earned by deceased officers should be transmitted "to their respective families." The Gold Cross that was, under these regulations, instituted is as follows:

A Maltese Cross, 1½ inches square, with an ornamental border; in the centre, a lion, facing right; in each limb of the cross the name of one of the actions for which it was conferred. The back of the cross is the same as the front. The cross was precisely the same irrespective of whether it replaced a large or a small medal. The clasps were all of the same pattern, whether worn with the cross, the large gold medal, or the small gold medal. They are 2 inches in length by ½ inch in width, and bear, within a border of laurel, the name of the action for which they were conferred.

At the close of the war in the Peninsula the issue of this handsome and much coveted decoration was discontinued, the enlargement of the Order of the Bath (January 1815) affording another method of reward which the Crown deemed more appropriate. On the occasion of this extension all officers who had obtained the cross with one clasp, i.e. who had been decorated for five or more actions, were made Knights Commander of the Bath. In all 847 awards of this superb decoration were made. The medal alone went to 469 officers, whilst 142 received it with one clasp, and 72 with two clasps. The cross was issued singly in 61 cases, with one clasp in 46, with two in 18, with three in 17, with four in 8, and with five clasps in 7 cases. The cross with six clasps was gained by Sir Colin Campbell (Lord Clyde), Sir Alexander Dickson (d. 1840) and Sir George Murray (d. 1846). Two officers, Viscount Beresford and Sir Denis Pack (d. 1823) received it with seven clasps. The duke of Wellington's had nine, the decoration thus commemorating fourteen out of the twenty-six battles, sieges or operations for which the Gold Medal of Military Merit was made. Wellington's were the 43rd平行部队, the 55th平行部队, the 71st平行部队, the 73rd平行部队, the 9th平行部队, the 28th平行部队, the 42nd平行部队, the 6th平行部队, and the 1st平行部队.

MEDAL

After the close of the Great War, however, do we meet with the real prototype of the war medal as we know it to-day; for the Waterloo Medal of 1815 is the first actual "general" medal that was ever issued, because it was issued precisely alike to all ranks. In the twelve cases in which we have seen that medal was given to all ranks, the medals differed either in size or in metal, or in both, according to the rank of the recipient, and in eight out of the nine issued by the Hon. East India Company the award was withheld from the British officers and men employed. Again in none of the cases quoted were the awards made by the Crown. The "Dunbar" medal was awarded by the Commonwealth parliament. The men of the Nile and Trafalgar wore their medals through the generosity of private individuals. In the other nine cases the award was made by the directors of the East India Company. It was with the issue of the Waterloo Medal that all this was changed and for this well-merited and much prized boon the Services owe all gratitude to the duke of Wellington. Writing from Orville on June 28, 1815, to H.R.H. the duke of York, he says:

"I would likewise beg leave to suggest to your Royal Highness (the then Commander-in-chief) the expediency of giving to the non-commissioned officers and privates of the British forces engaged in the battle of Waterloo, a medal. I am convinced it would have the best effect in the army; and, if that battle should settle our concerns, they will well deserve it."

Again, writing from Paris, Sept. 17, 1815, to Lord Bathurst, the then secretary:

"I have long intended to write to you about the medal for Waterloo. I recommend that we should all have the same medal, hung to the same riband as that now used with the medals." (i.e. the army gold medals and crosses). It is also fair to point out that in his place in the House of Commons, and on the day after the duke's letter to the commander-in-chief had been penned, William Watkins Wynn urged that medals should be given to the survivors of Waterloo, and that they should be replaced by a medal for the British, and that men who had been fellows in danger might bear the same badge of honour." And so came into being that type of "general" medal, which beginning with Waterloo has continued down to the present.

The description of these later medals, and the points of interest about them, will now be given as fully as exigencies of space will allow.

1. Waterloo, 1815.—Awarded by the Prince Regent, 1816. Obverse: in the form of the Waterloo medal. Reverse: Figure of Victory seated; in her right hand, a palm branch; in her left, an olive branch. Above, WELLINGTON; below, WATERLOO, JUNE 18, 1815. Ribbon: Crimson with blue borders (i.e. the clasps N. and S.).

The notification of this award was made in a memorandum by H.R.H. the commander-in-chief, dated Horse Guards, March 10, 1816, and it is worth noting that the prince regent commanded that the ribbon "shall never be worn but with the medal attached to it." The medal was conferred on all the British troops, including the King's German Legion, present on the 17th June at Quatre Bras, on the 17th in the fighting that took place during the retirement through Genappe to Waterloo, and on the 18th at Waterloo. It was also given to four regiments, 2nd Batt. 53rd, 1st Batt. 54th, 2nd Batt. 59th, and 1st Batt. 91st Regiment of Foot, which formed Sir Charles Colville's Brigade, which was detached. The reverse of this medal would appear to have been copied from the Greek Coin of Eubia, about 450 B.C., a specimen of which is in the British Museum. The medals most prized by collectors are those of the 2nd and 3rd Guards (the 1st Union Brigade) and the 28th and 42nd Regiments of Foot, as those regiments suffered very severely and consequently fewer survivors received the medal than in other corps.

2. Ghuznee, 1839.—Awarded by the Government of India, 1842. Obverse: The Gateway of the Fortress. Below, GHUZNEE. Reverse: In centre a space for name of recipient; above, 23rd July; below, a mural crown with underneath it 1839; the whole within a laurel; Ribbon: Particoloured, crimson and green (Plate I.). Clasps: Nil.

This medal originated with Shah Soojah, whose part the Indian government took in the Afghan troubles of the time. His downfall occurred (Bengal Military Proceedings, May 27, 1842; Nos. 151 and 152) and leaving the reason for before the medals were ready, the actual award was made by the Government of India. It was originally ordered (Bengal Military Proceedings, May 27, 1842; Nos. 151 and 152) and leaving the reason for before the medals were ready, the actual award was made by the Government of India. It was originally ordered (Bengal Military Proceedings, May 27, 1842; Nos. 151 and 152) and leaving the reason for before the medals were ready, the actual award was made by the Government of India. It was originally ordered (Bengal Military Proceedings, May 27, 1842; Nos. 151 and 152) and leaving the reason for before the medals were ready, the actual award was made by the Government of India.
The medal was awarded to all troops of both the Crown and of the Company that were actually present at the siege and capture of the fortress, July 21, 22, and 23, 1839.

The St Jean d’Acre medal, as it is commonly called, was awarded to the officers and men of the British fleet that were engaged in the operations against the fortress of St Jean d’Acre, originally Surgeon-Major Pollock at Calcutta. The medal was used to denote the actual part taken in the operations by the recipient, in the manner that is now done by clasps. Of these clasps there is only one known, which has been transferred to the small portion of his army that Major-General Nott left behind him in Candahar. The medal with the No. 2 reverse is also rare, as its distribution was very limited.

MEDAL

This award, given to all the troops, both Crown and Hon. East India Company engaged in the First Sikh War, was first notified in governor-general’s G.O., dated Camp, Ferozepore, December 25, 1845, to the General Commanding the Field Force, and received its first general issue given six months later. As there was a considerable number of troops engaged in this campaign, the medal is not a very rare one, but a very rare combination is the medal with Ferozeshahur in the exergue, on the reverse, as well as the medal with “Koh-i-Noor” on the obverse, as this combination was never issued to any person within the Service. The reverse of the medal shows a clasp for the capture of the town of Ferozepore, and as will be seen the medal was awarded only for those actions or operations for which the Army Gold Medals (including that for Maida) had been awarded; and in addition for the operations in May 1849 and 1850, for the liberation of the Indus, when two medals were issued with fifteen clasps, though several survivors proved their claim to fourteen clasps. In fact medals with seven, twelve, and eight clasps are not common, those with ten, or more, distinctly rare. For the capture of Ferozepore (including those of the King’s German Legion), three were issued with 14 clasps, three with 13, nine with 12, twelve with 11, thirty-six with 10, eighty with 9, and one hundred with 8.

1 In either one or both actions, only one clasp awarded.

2 A similar clasp was given in several N.G. medal.

13. Punjab, 1848–49 (2nd Sikh War).—Awarded by Government of India, 1849. Obverse: Head of Queen Victoria as in First China Medal. Reverse: Sikh chieftains delivering up their arms to Sir Walter Raleigh Gilbert, near Rawal Pindi, March 14, 1849. Above, TO THE ARMY OF THE PUNJAB. In exergue, MDCCCCLXIX. Ribbon: Blue with yellow stripes at side. (Plate 1.) Clasps: M. G. HILL; BENBOW; B. WALLER; G. K. ALEXANDER.

The award of this medal was first notified by a G.O. of the governor-general, dated Camp, Ferozepore, April 2, 1849. The medal is one of the most curious of its kind, as it is not to the whole body of officers and men of the British Army, but to a very small select body of officers and men, who were engaged in an action against the Sikhs on 3rd April 1849, and who had been employed in the Punjab in this campaign to the date of the occupation of Peshawur.

In other words it was granted to all who had served during this campaign within the territories of Maharajah Duleep Singh, irrespective of whether they had qualified for any of the clasps. A very large number of medals was therefore issued without clasps. Another interesting point about this award is that after its grant it was laid down that in future no medals were to be issued by the Government of India without the consent of the Crown. As a matter of fact the Government of India was for the future only concerned in the grant of the two medals that followed, as the Medals of the First and Second Sikh Wars were issued without any more than two clasp. The clasp either being either “Moootan” and “Goojerat” or “Chillianwala” and “Goojerat.” Very rare medals are those of the 4th Foot with Clasps of “Chillianwala” and “Goojerat” given to a soldier who had been served in the Punjab and the Punjab in this campaign to the date of the occupation of Peshawur.

As a matter of fact the Government of India was for the future only concerned in the grant of the two medals that followed, as the Medals of the First and Second Sikh Wars were issued without any more than two clasp. The clasp either being either “Moootan” and “Goojerat” or “Chillianwala” and “Goojerat.” Very rare medals are those of the 4th Foot with Clasps of “Chillianwala” and “Goojerat” given to a soldier who had been served in the Punjab and the Punjab in this campaign to the date of the occupation of Peshawur.

In other words it was granted to all who had served during this campaign within the territories of Maharajah Duleep Singh, irrespective of whether they had qualified for any of the clasps. A very large number of medals was therefore issued without clasps. Another interesting point about this award is that after its grant it was laid down that in future no medals were to be issued by the Government of India without the consent of the Crown. MEDAL

DEIG, NEPAUL, KIRKEE, POONA, KIRKEE-POONA, SAMANA, GURPORE, MAHDEPOOR, CORYGAUM, AVA, BHURPOOR.

This medal was awarded "to the surviving officers and soldiers of the Crown and of the East India Company who took part in any operations authorized or carried out by the Government of India in Nepal and Burma, during the first twenty-five years of the 19th century, including the officers and seamen of the Royal Navy, and the Company's Marine who took part in the first Burmese War with the government of the King of Ava in 1824..."

The combination of this medal with other medals is very numerous, but medals with more than two or three clasps are rare. Seven is probably the greatest number awarded with any one medal, and a medal with more than seven clasps is very rare.

NAGA MEDAL

This medal was awarded to the Company's officers and soldiers for services during the Naga campaign, organized in 1823, and during the campaigns of 1825-26 and 1827-28.

MEDAL

The Royal Navy or Indian Marine, or both, received the medal with these clasps.

12

1. Whether in one or both actions, only one clasp awarded.
2. The Royal Navy or Indian Marine, or both, received the medal with these clasps.
largest number of clasps to any one medal is four. Certain non-combatants received the medal without a clasp.

18. **Naval Queen Victoria, 1856.**

Obverse: Head of Queen Victoria as in First China Medal Reverse: Britannia seated and holding a trident in her right hand. In the background the word ABROAD, BALTIC, C. INDIA, &c., 1854-55. Ribbon: Yellow with white edges (Plate I.).

This award, notified by Admiralty Order, June 5, 1856, was granted "to the officers and crewers of Her Majesty's ships, as well as to the officers and crewers of her ships-of-war engaged in the operations in the Baltic in the years 1854 and 1855."

The medal is, of course, practically a naval one, but two officers and ninety-nine men of the Royal Engineers were employed in the expedition, and having a map of the Crimean spread over the wheel and breeches, it is interesting to note that they were not overlooked.

19. **Turkish Crimean Medal.**—Awarded by the Sultan, 1856.

Obverse: A trophy composed of a field piece, a mortar, and an anchor. Legend, VICTORIA REGINA and the year of the issue. Behind are the British, French and Sardinian flags. The flag of the nation to which the recipient belonged is in the foreground, and those of the two other nations in the exergue, "Crimea 1855," "La Crimee 1855," or "La Crimea 1855," according as to whether the medal was intended for British, French or Sardinian recipients.

This medal was distributed to all of the Allied Forces, both naval and military, and to such volunteers as accompanied those engaged, and to the officers and private soldiers employed in the government and citizens of the United States; also to the "commanders and crews of the several expeditions which originated in the zeal and humanity of Her Majesty's subjects"; and finally to those "engaged without pay or prospect of reward." (See Les Médailles de l'Empire royaume, by W. Froment.)

20. **Arctic, 1818-1855 (First Arctic).**—Awarded by Queen Victoria, 1857.

Obverse: Head of Queen Victoria, wearing a tiara. Legend, VICTORIA REGINA. Reverse: A ship blocked in the ice, icebergs to right and left, and in foreground a sledding party. Above, FOR ARCTIC DISCOVERIES. In exergue, 1818-1855. Ribbon: White (Plate I.).

This award was first notified in an Admiralty Notice dated, January 30, 1857. It was given to the crews of Her Majesty's ships employed in Arctic exploration, and also to the officers of the French Navy, and to such volunteers as accompanied those engaged. It was re-issued in 1862.

Obverse: Head of Queen Victoria as on First China Medal. Reverse: Britannia standing facing left with a lion on her right side; her right arm is extended, letting out a wreath; on her left is a helmet, and in her left hand, and in her left hand, a spear. Scroll, VICTORIA INDIA. In exergue, 1857-1858. Ribbon: White, with two red stripes, forming five ½-inch stripes (Plate I.).

Obverse: Delhi (Plate I.), Inscription: To the British in India, 1857-1858, for services in the First Insurrection in the United Provinces, from Jan. 29, 1857, to Sept. 25, 1857; RELIEF OF LUCKNOW (Nov., 1857); LUCKNOW (March 2 to 21, 1858); CENTRAL INDIA (Jan. to June 1858).

The grant of this award was first notified in a despatch from the Court of Directors to the Government which stated that "the Queen has been graciously pleased to command that a Medal shall be granted to the troops in the Service of Her Majesty, and of the East India Company, who have been, or may be, employed in the suppression of the Mutiny in India."

This is the last medal given by the Honourable East India Company. The medal without clasp was given to all those who were present at Amouli, and the actions between that place and Coomassie (including the capture of the capital), and of those who, during the five days of those actions, were engaged on the north of the Prah in maintaining and protecting the communica- tions with the troops of the river. The medal was awarded to all who were engaged, and 11,000 medals were issued for the Ashantee campaign to both Services. Over eighteen years later this same medal was re-issued as a "general service" medal, the award being for operations in the Soudan and Egypt. It was re-issued in 1882, during the period 1887-92, which were covered by the dated clasps "1887-8," "1891-2," and "1892." As such the issue was continued for operations down to the year 1900, although the official title "West India Medal" was changed to "Coomassie Medal." The new issue is in the same metal and consists of 455 medals awarded to the Royal Navy and Royal Marines, and to officers and 157 to noncommissioned officers and privates of the army.

In addition to this award the French emperor sent five hundred of the same medal, "with the approval of the Queen," to selected non-commissioned officers and men of the army and Royal Marines, and petty officers and seamen of the Royal Navy. Only two of these medals were awarded to officers, viz. the Duke of Cambridge and the Duke of Clarence, the former for services in Egypt, the latter with his own medal.

The King of Sardinia also distributed 450 medals to the Royal forces, of which 50 were given to the Royal Navy and Royal Marines, and 243 to officers and 157 to non-commissioned officers and privates of the army.

Various officers who served on the staff, as, for example, Field Marshals Earl Roberts and Sir Henry Norman. With regard to the Royal Navy and Royal Marines, the officer commanding the 17th (London) Light Brigade, under Captain Peel, received the medal with both his clasps "Relief of Lucknow," "Lucknow," the "Pearl's " brigade, under Captain Sothby received the medal without clasp. This is the medal that the prime minister Sir Robert Peel received, which was first used for the China Medal of 1842, and of which W. Wyon, R.A., was the artist.

21. **Naval Queen Victoria, 1868.**

Obverse: Bust of Queen Victoria, with diadem and veil around an indented border, between the nine points of which are the letters A.B.Y.S.I.N.T.A. Reverse: Within a beaded circle the name of the ship and the year of issue. The legend, VICTORIA REGINA, of the same size as the foreground inscription, a wreath of laurel. Ribbon: Red, with broad white borders (Plate I.).

22. **New Zealand, 1845-47, 1860-66.**—Awarded by Queen Victoria, 1869.

Obverse: Bust of Queen Victoria as on Abyssinian medal, but larger. Legend: VICTORIA D:G: BRITT: REG: F:D: Reverse: Dated, with diadem and veil behind, by L. C. Wyon. In exergue, 1845-47, and 1860-66. The grant of this award to the Army was notified in an Army Order, dated March 1, 1869, and its extension to the Royal Navy and Royal Marines by an Admiralty Order, dated June 3, 1869. The medal was awarded to all those who had been employed in the operations of New Zealand in which the recipient served. Above, NEW ZEALAND; below, VIRTUTIS HONOR. Ribbon: Blue, with a broad red stripe.

The grant of this award to the Army was notified in an Army Order, dated March 1, 1869, and its extension to the Royal Navy and Royal Marines by an Admiralty Order, dated June 3, 1869. The medal was awarded to all those who had been employed in the operations of New Zealand in which the recipient served. Above, NEW ZEALAND; below, VIRTUTIS HONOR. Ribbon: Blue, with a broad red stripe.

23. **West Africa, 1873-1900.**—Awarded (originally as the "Ashantee" medal) by Queen Victoria in 1874, with the exception of the last part, with clasp "1900," which was awarded by H.M. Government of the Ashantee, 1877-1888; also awarded to the Government of India, 1891-2.

Obverse: Head of Queen Victoria as on First China Medal. Reverse: Britannia standing facing left with a lion on her right side; her right arm is extended, letting out a wreath; on her left is a helmet, and in her left hand, a spear. Scroll, VICTORIA INDIA. In exergue, 1873-1900. Ribbon: Blue, with black stripes.

24. **Sudan, 188-89.**

Obverse: Head of Queen Victoria as on First China Medal. Reverse: A palm tree, with an inscription, in the foreground, VICTORIA REGINA. In exergue, 1888-89. Ribbon: Black, with red stripes.

25. **Cape Colony, 1880-81.**

Obverse: Head of Queen Victoria as on First China Medal. Reverse: Britannia standing facing left with a lion on her right side; her right arm is extended, letting out a wreath; on her left is a helmet, and in her left hand, a spear. Scroll, VICTORIA INDIA. In exergue, 1873-1900. Ribbon: Blue, with black stripes.

26. **Cape Colony, 1880-81.**

Obverse: Head of Queen Victoria as on First China Medal. Reverse: A palm tree, with an inscription, in the foreground, VICTORIA REGINA. In exergue, 1880-81. Ribbon: Black, with red stripes.
**MEDAL**

Africa Medal (see Army Order 765, of Dec. 1894) is somewhat of a misnomer, for very frequently the medal has been granted for services in Central Africa and in the Hinterland of the East Coast as for services on the West Coast. In all issues since the original "Kandahar" Medal, the clasp only is given. But those who had the medal and those of the same issue do not make it a new award. As will be seen later, the same medal was subsequently issued with a different ribbon, and so constituted as an entirely new decoration, the same clasp being worn on both. The exception is the ribbon, the exception of those issued with "Mwele, 1895" engraved on the medal, none of these medals have been issued without a clasp, since the original issue for the campaign of 1873-74; and the clasp dates also. This limited the first issue by the only one that has been issued to regimental units of the British Army as apart from the West India Regiment and local troops. The clasp was issued, baronial and colonel's regiments, was purposefully excluded from the list of those to which this medal was first awarded, and it is said that yellow and black (the Imperial Russian colours) were chosen as the colours of the ribbon, in compliment to his consort the grand duchess Marie of Russia.

24. Kandahar, 1879. (Plate II.)

**MEDAL**

At the conclusion of the first phase of the Second Afghan War, it was proposed that the (Second) India G.S. Medal should be issued for this campaign with clasps "Afghanistan," "Ab Musjid," and "Peshawar." After the massacre of Sir P. L. N. Cavagnari and the members and officers of the 14th Lancers, which took place on Sept. 13, 1879, and the consequent renewal of the war, it was decided to grant a separate medal. The first official intimation of the award is in the official Gazettel dated Aug. 7, 1880, and also in the official medal issued to the 77th Punjabis. The British Medals, dated Nov. 22, 1878, and May 26, 1879, (first phase of the war), and between Sept. 1879 and Aug. 15, 1880 for the Khyber and Kurram Lines. Also to the Afghans. In 1879-80, 78-90. Ribbon: Green, with crimson borders (Plate I.). Clasps: (See Medal). The "Kabul" was awarded to all who had shared in the operations "at and near that place from the 10th to the 23rd Dec., 1879, including the column under the command of General Sir J. G. Bourchier. The clasp was given to the 77th Punjabis, under Sir Frederick Roberts on the 24th Dec., 1879. The clasp for "Kandahar" did not include the whole garrison of the beleaguered city, but only to the troops actually engaged in the action fought under Sir Frederick Roberts on the 1st April, 1879. Ayub Khan on the 1st Sep., 1880. The greatest number of clasps with which the medal was issued was four, and the units to which such medals were issued are the 77th Highlanders, Sylhet, 14th Lancers, 7th Gurkhas, 5th Punjab Infantry and 3rd Punjab Pioneers. The bust of the Queen by Sir Edgar Boehm, R.A., has not been reproduced on any medals.

25. Kabul to Kandahar, 1880.—Awarded by Queen Victoria, 1880. This decoration took the form of a five-pointed star, 1 in. across from point to point, with a ball between the points; between the ball and the star were the Imperial Crown and ring for suspension. Obverse: In the centre of the medallion is inscribed "KABUL TO KANDAHAR," in V.R.I, surrounded by a band inscribed KABUL TO KANDAHAR, 1880. Reverse: Plain, with a hollow centre, round which the recipient's regimental number is inscribed. The old rainbow-coloured military ribbon is worn with this star. The grant of this award was first notified in a despatch from the secretary of state for India to the vicerey, dated Nov. 30, 1880. This awarded the decoration to the following recipients of Queen Victoria, Kabul to Kandahar; and later, Aug. 26, 1881, a G.O.B. by the Governor-General extended the grant "to the troops which then composed the garrison of Kelat-i-Ghilzai, and accompanied the force under the command of Lieutenant-General Sir F. S. Roberts, G.C.B., V.C., from that place to Kandahar.

26. Afghanistan, 1879-80 (2nd Afghan). Awarded by Queen Victoria, 1880. Obverse: Bust of Queen Victoria, crowned and with veil, by J. E. Boehm. This is the first war medal bearing the monogram of the Queen, and that was given to the troops of the Army. Reverse: A column of troops emerging from a mountain-pass, headed by a heavy battery carrying a gun; behind, marching troops. The Obverse is "AFGHANISTAN" and the Ribbon is green. (Plate II.) Clasps: (See Medal). ALI MUSJID, PEIWAR KOTAL, CHARASIA, KABUL, AHMED KHEL, KANDAHAR.

Note: Date following Title is that of authorization of first award, those under Titles are the year, or years, in which the operations for which the Medal was awarded took place.
MEDAL

31. Canada (General Service).—Awarded, 1899. Obverse: Head of Queen Victoria, as in Third India G. S. Medal. Reverse: Within a maple wreath, the Dominion flag, above, CANADA, Ribbon: Red, yellow, blue, (Plate I), Clasp: JIDBALLI, GRAND RAPIDS, 1897; FENJAN RAID, 1897; RED RIVER, 1875. One battalion of the King’s Royal Rifles received this medal with the Red River Clasp. Otherwise issue confined to Canadian forces.

32. ’Uganda’, 1896–1900.—Awarded to any soldier of Queen Victoria, 1899. Obverse: Half-length effigy of Queen Victoria holding sceptre, by De Saulles, as in “Uganda” medal described below. Reverse: A winged Victory, seated, with, on either hand, the Union Jack and the Egyptian flag. The left hand holds a laurel wreath, the right a palm branch. On a tablet below, SUDAN, and below this lotus leaves. Ribbon: Half black, half yellow, divided by a narrow strip (Plate I). The reverse shows operations under the command of Sir Herbert (Lord) Kitchener, which led to the reconquest of the Sudan, 1898; issued in bronze to followers.

33. ‘Kimbols’ Sudan, 1896–1900.—Awarded by the khedive in 1897. Obverse: “Abbas Hilmi II.” and date, in Arabic. Reverse: A trophy of arms with a shield in the centre, on a tablet below “Recovery of the Sudan,” in Arabic. Ribbon: Yellow, with blue centre (Plate I). Clasps: FIKRET, HAFIR, SUDAN, 1897; SUDAN, 1898; ABU HAMED, THE ATBARA, KHAMIR, TOUNG GEDAREF, SUDAN, 1899; SUDAN, 1900; CEDID, IV. SUDAN, 1900; SHAHZAD, 1900–1902; TEROK, NYAN NYAM, TALUDI.

This medal was awarded to officers and men of the British Navy, and Army, to the Egyptian Army engaged in the reconquest of the Sudan. The reverse has the date of the various battles, and the ribbon is not described.

34. Cape Colony General Service, 1900.—Awarded by the government of Cape Colony. Obverse: Bust of Queen Victoria as on the Volunteer Long Service Medal. Reverse: Arms of Cape Colony. Ribbon: Yellow, with blue centre (Plate I). Clasps: BASUTOLAND, TRANSKEI, BECHUANALAND. Issued to Colonials only, for services in various minor campaigns.

This is the first war medal issued by a chartered company since the close of the Company’s rule in India. It was awarded to British officers and men of the British Service, to the Cape Mounted Rifles, Bechuana, and those chartered Company’s own forces, engaged in the Matabeleland and Mashonaland Campaigns 1893, 1896 and 1897.

This medal only differs from the West African in that it has a different ribbon. It is suspended by a ring. Practically only the local forces (and of course their British officers) received this medal. But it bears the same effigy of the Indian and Royal Navy have also received it.

37. East and Central Africa, 1899 (the “Uganda” Medal).—Awarded by Queen Victoria in 1899. Obverse: Head of Queen Victoria, as in Ugandan Medal of 1899. Reverse: as in “Uganda” Medal above described. Ribbon: Yellow, with black edges and two narrow green stripes (Plate II). Clasps: N. NIGERIA, with various dates; S. NIGERIA, with various dates; UGANDA, 1900; JUBALAND, GAMBIA, LANGO, 1901 and 1902; JIDBALLI, KISSI, 1905; SOMALILAND, 1901 and 1902–04; BRITISH CENTRAL AF RICA, 1899–1900; ARO, 1901–02.

This medal represents an almost incessant warfare of a minor, but a very costly nature. British officers and men engaged with the Boers and Zulus, or with the Sudanese, or with the Somalis, or with the King’s African Rifles. It is worthy of note that in the Sudan, that a contingent of Boer mounted riflemen took part in the Somaliland Campaign, within one year of the peace of Vereeniging, and received the same medal as the British Forces. The reverse of this clasp represents indeed a considerable campaign in which contingents from Great Britain and India took part.

38. South African, 1899–1902.—Awarded by King Edward VII, in 1902, to the men of Queen Victoria’s death. Obverse: Bust of Queen Victoria, by De Saulles. Reverse: Britannia holding an outstretched laurel wreath towards a body of troops, in the background, with the Royal Shield with centre orange bordered by blue, outside edges red (Plate II). Clasps: see below.

The Queen’s Medal for troops engaged in the South African War was authorized, shortly after Queen Victoria’s death, by Army Order 94 of 1901. It was given “to all officers, warrant officers, non-commissioned officers and men of the British, Indian and Egyptian Forces, the Royal Navy, and Nursing Sisters, who actually served in South Africa between 3rd April, 1899, and a date to be fixed hereafter” (the war not being concluded) “to all troops stationed in Cape Colony and Natal at the outbreak of hostilities, and the Heeren/Boers troops in Natal between 3rd April, 1900, and a date to be fixed hereafter.” The last provision avoids a widening of the signification hitherto attaching to “war service” for the troops at St Helena were employed in guarding Boer prisoners. The Army Order was issued on 3rd November 1901 and 1902. Clasps were authorized as follows: BELMONT (Nov. 23, 1899); MODDER RIVER (Nov. 28, 1899); PAARDEBERG (Jan. 24, 1900); XILEN (June 9, 1900); GEDAREF (May 8, 1900); NELSON (May 26-27, 1900); WITTEBERGEN (July 1-9, 1900); DEFENCE OF CAPE COLONY (Oct. 13-23, 1900); REIEF OF KIMBERLEY (Feb. 15, 1900); DEFENCE OF MAFEKING (Oct. 13, 1899—May 17, 1900); REIEF OF VREDEFORT (May 18, 1899—July 7, 1899); ELANDA LAAGTE (Oct. 21, 1900); DEFENCE OF NELSON (Nov. 3, 1899—Feb. 28, 1900); TUGELA HEIGHTS (Feb. 14—27, 1900); RELIEF OF LADYSMITH (Dec. 15, 1899—Feb. 28, 1900); MALEBOY (June 2-9, 1900).

Clasps: for CAPE COLONY, NATAL, ORANGE FREE STATE AND RHODESIA, were given to troops who served within the limits of the respective colonies and states named during the war, without Clasps present at any engagement, for operations during the Boxer rebellion a clasp was awarded. Non-enlisted men, of whatever nationality, who drew military pay were awarded the medal in bronze instead of silver. This was followed by a list of those who volunteered and were sent to Mediterranean stations to release the forces for field service were awarded (Feb. 1902) the medal without clasp. Mediterranean "being substituted for "South Africa" on the reverse of the Medal, was issued to any one entitled to the Queen’s Medal for South Africa.

39. The "King’s" South African Medal was awarded by King Edward VII, in 1902, to be worn in addition to the "Queen’s" by those who completed eighteen months’ service in South Africa during the war. On the obverse of the medal is the effigy of King Edward, by De Saulles (as on the "Ashanti, 1900," Medal); the reverse is the same as that of the "Queen’s" Medal. Ribbon: Green, white and orange (Plate II). The two clasps awarded were, in accordance with the terms of the award, general in character, to wit, SOUTH AFRICA, 1901 and SOUTH AFRICA, 1902.

Obverse: Bust of Queen Victoria as on "Queen’s" South African Medal. Reverse: As on first China Medal, but with date altered. Title: In first line, "MEDAL OF DEFENCE OF LEGATIONS, RELIEF OF PERIN, TAKU FORTS." This medal was issued to the Royal Navy (including some Naval volunteers), British and Indian Armies, and the (Wei-hai-Wei) Chinese Expeditionary Force for operations during the Boxer rebellion. This was the last war medal, as the "First China" was the first to bear Queen Victoria’s effigy. Sir E. H. Seymour, the commander of the Tientsin relieving column, who had taken part in the former China medal, received it as a special presentation.

45. India, 1895 (Third India General Service).—Awarded by Queen Victoria in 1896. Obverse: Bust of Queen Victoria, by De Saulles. Ribbons: A. E. R. A. Ribbon: Two red and two green stripes of equal width (Plate I). Clasps: DEFENCE OF CHITRAL, 1895; RELIEF OF CHITRAL, 1895; MALAKAND, 1895; KETA, 1897; TRINCH, 1898; TIRAH, 1897; TIRAH, 1895; WAZIRISTAN, 1901; 02.

The ribbon of this medal is perhaps more frequently seen than
MEDAL

that of any other British war medal except those for South Africa. In 1903 the medal was re-issued with the military effigy of King Edward VII (Plate II) on the reverse and the date was omitted from the reverse. The medal is issued on bronze, without clasps, to followers.

47. We met this King Edward VII in 1905. Obverse: Military effigy of the king as on Ashanti, 1900, medal. Reverse: A representation of the Potala at Lhassa. Ribbon: Purple-red, edged with green and white stripes (Plate II). Clasp: GVII. 50.

49. Polar Medal (or Antarctic Medal).—Awarded by King Edward VII as a reward for the heroism of those who have served in the Arctic regions since 1853. The medal is a white enamel Star, 15 mm. wide, with two thin stripes near the edge (Plate II). Clasps: SOUTH AFRICA, 1899–1902; CHINA, 1900. This medal is restricted to officers of the mercantile marine serving in chartered troop-ships. It is a sort of general service medal as far as service is concerned, irrespective of individual distinction or bravery. There are other classes of medals and decorations, civil as well as military, which must be grouped with them, as being allied in character. These are either (i.) awards personal to the recipient, being an acknowledgment of or reward for special individual services or good conduct (these are civil as well as military in respect of awards for bravery), or (ii.) awards that are simply of a commemorative kind, though worn as war medals and for the most part given to officers and soldiers. The more important of these two classes will be named. Orders given for service are dealt with, for the most part in the article KNIGHTHOOD; but particulars are given here of certain distinctively military orders that have no knighthood rights and duties, and indeed little meaning apart from the deeds or services which led to the award—being so to speak, records of the past, rather than badges of a present membership. Individual decorations for services may be classed as (i.) for gallantry, (ii.) for special merit, and (iii.) for long service and good conduct.

1. Indian Order of Merit.—Awarded by H.E.I. Company and notified by Government of India, 11th April, 1877, under the 19th Amendment of the Act of 1858. 1st Class—a Gold Star, 1½ in. diameter; in the centre, in gold on a ground of dark blue enamel, crossed swords within a circle around which is the legend, REWARD OF VALOUR, the whole encircled by a gold laurel wreath. 2nd Class—Star similar to that of 1st Class, but in silver. Wreath and centre as in 1st Class. 3rd Class—Star exactly similar to that of 2nd Class, but the wreath and centre in silver, and dark blue enamel and silver, respectively. Reverse: Engraved 1st, 2nd and 3rd Class Order of Merit, respectively, but the name of the recipient is not engraved on the decoration when issued. Ribbon: Dark blue, with red edges. This decoration is to be obtained only by a "conspicuous act of individual gallantry" in the field or in the attack or defence of fortified places. It is open to all native officers or soldiers of the Indian Army, "without distinction of rank," and is bestowed for any act of gallantry to the first act of gallantry for which the recipient is recommended. The 2nd Class is given only to those who possess the third, and for a second act of conspicuous gallantry. The 1st Class is given only to those who possess the second, and for the third act of gallantry. If a recipient of the decoration receives an additional allowance equivalent in the 3rd Class to one-third, in the 2nd to two-thirds, and in the 1st to three-quarters of the ordinary pay of his rank, over and above that pay or his pension, and (in the case of a widowed wife, the first received) the pension of the Order for three years after her husband's death.

2. Victoria Cross.—Instituted by Royal Warrant, January 29, 1856. A bronze Maltese Cross, 1½ in. diameter, with, in the centre, the Royal Crest (lion and crown), and below it a scroll inscribed "FOR VALOUR." There is a bronze laureated bar for suspension connected with the cross, but the name, rank and corps of the recipient are engraved on the back of the laureated bar. Ribbon: Red for the army; blue for the navy. Clasp: For every additional act of bravery characterising the action for which the first class medal was awarded. Nothing save "the meritorious act of bravery" gives claim for the decoration, and it must be evinced by "some signal act of valour or devotion to their country" performed in "the presence of the Enemy."

5. Maltese Cross (for valour in action).—Instituted by Royal Warrant, 7th of February 1881, authorized for clasps for subsequent acts of gallantry.

6. Distinguished Conduct in the Field (Army).—Instituted by Royal Warrant, 13th April, 1877. A bronze oval Medal, with the name of the recipient, "GRANVILLE," engraved on it in a oval, with "DISTINGUISHED CONDUCT IN THE FIELD" lettered around it, above and below. Ribbon: A white ribbon, two white stripes (1 in. wide). Clasps: As authorized in original warrant. 2nd Class—Institute by the Meritorious Service Medal, as authorized in the original warrant. The decoration was re-instituted in two classes, as follows. 1st Class—Badge precisely as already described. Ribbon: Dark blue, with four white stripes (1½ in. wide). Clasps: As authorized in original warrant. 2nd Class—Badge exactly similar to that of the 1st Class, except that it is entirely worked in bronze, instead of gold and bronze. Ribbon: Dark blue, with two white stripes. Clasps: As authorized for 1st Class.

The decoration is awarded only to those who "have, in saving or endeavouring to save the lives of others from shipwreck or other perils at sea, or otherwise (as the case may be) made a meritorious act of noble and conspicuous heroism" to "cases of extreme and heroic daring"; the 2nd for acts which, though great courage may be shown, are not sufficiently distinguished to deserve to be classed as of the 1st Class.

5. New Zealand Cross.—Instituted by an Order of the governor of New Zealand in council, 10th of March, 1869. Silver Maltese Cross, rounded at the top by a V, to a silver bar ornamented with laurel in gold. The name of the recipient is inscribed on reverse. Width of Cross, 1½ in. Ribbon: Crimson. Clasps: Authorized for subsequent acts of valour. In authorizing this decoration Sir G. F. Bowen, the then governor, went outside his authority, but the Queen ratified the colonial order in council, and approved "Her Majesty's consent thereto as bound by it may be considered as established from that date by her direct authority." It was, however, stipulated that the occasion was in no way to form a precedent. The award was to be for those "acts by particular individuals and not for service in action, or devotion to their duty while on service," and only local "Military, Volunteers or Armed Constabulary" were to be eligible. In all, 13 or 14 of these decorations were awarded. No clasps were awarded.

6. Conspicuous Gallantry (Navy).—Instituted by an Order of the Queen in Council, 7th of July, 1874. Obverse: Head of Queen Victoria, by W. Wyon, in oval medallion, full figure, with Naval crown, and laurel wreath, and within FOR CONSPICUOUS GALLANTRY. Above, a crown. Ribbon: Three stripes of equal width, outside blue, and inside dark blue (Plate II). Clasps: None authorized. To reward "acts of heroism not connected with the Enemy." Only petty officers and seamen of the Royal Navy, 1Now naval effigy of King Edward VII, as on Transport Service Medal.
and non-commissioned officers and privates of the Royal Marines, are eligible for this decoration. Prior to the institution of this decoration, acts of gallantry by sailors and marines were rewarded by a small button, given to men before the year 1847, for distinguished conduct in the field was instituted, viz. the "Meritorious Service" medal. If the holder be a Chief or First Class Petty Officer, or a Sergeant of Marines, the award carries with it the post-nominal letters of a gold leaf, attached by a ring to the top of the crown, and is worn round the neck, outside the uniform. Ribbon: Originally sky-blue, changed to crimson 1838.

2. Obverse: Crown, and inscribed, for Ability and Good Conduct. Ribbon: None authorized.

3. The official documents as regards the institution of this decoration are now to be found at the Admiralty, but only engineers were eligible for the award, and it carried no gratuity or annuity. Only six were ever awarded. When, in 1847, engineers were raised to the rank of "Sailors," the warrant of 1846 superseded the former; but an annuity of 8 l. 10s. 0d. was added, and a medal was awarded for the same conduct as before.

4. The Distinguished Service Order (see Knighthood) is only given to officers (and naval and military officials of officer rank, not including Indian native officers) for services in war. Often it is the reward of actual conspicuous gallantry under fire, but its purpose, as defined in the Royal Warrant instituting the order, is to reward "individual instances of meritorious or distinguished service in the field;" and the same document declares that only those shall be eligible "who have, in the course of active service, rendered services of a meritorious or distinguished service in the field, or before the enemy." In the main, therefore, it is awarded for special services in war, and not for the rendering of good conduct, the latter being considered a fact generally rendered in action. The order is in no sense a sort of second class of the Victoria Cross. Like the latter, the Distinguished Service Order is generally referred to by its initials.

5. The Royal Red Cross is also an Order. Membership is restricted to women (not necessarily British subjects), and is given as a reward for naval or military nursing service. Instituted 1883.

This decoration was instituted in 1892, and is the reward for twenty years of service in the commissioned ranks of the volunteer force. It is generally called the V.D. Since the conversion of the Volunteer Force (1899) it may be replaced by the Territorial Officers' Decoration. Officers of the Royal Naval Reserve and of the Royal Naval Volunteer Reserve are eligible for a non-commissioned decoration (1910). The Long Service and Good Conduct (Army) Medal was instituted in 1833. Obverse: A trophy of arms. Reverse: “LONG SERVICE AND GOOD CONDUCT.” Ribbon: Crimson, as for Meritorious Service Medal.
9. The Long Service and Good Conduct (Navy) Medal was instituted in 1835. Ribbon: Blue with white edges (Plate II).

10. The Volunteer Long Service Medal.—Instituted in 1894. Has a green ribbon. Obverse: Effigy of Queen Victoria. Reverse: An inscription on a ribbon, describing FOR LONG SERVICE IN THE VOLUNTEER FORCE. Replaced by the Territorial Long Service Medal (1908), of which the ribbon is green with a yellow centre; and the obverse a bust of the king. The Mutia Long Service Medal was instituted in 1835. The Long Service Medal a yellow ribbon, the Honourable Artillery Company’s Medal a black, red and yellow ribbon. All these are shown on Plate II.

12. The Medal for Naval Gunnery was instituted in 1903. Ribbon: Red centre, flanked by two narrow white stripes, two broad blue stripes at edges (Plate II).

Amongst medals of the last class may be mentioned the Jubilee Medal of 1887, the Queen Victoria’s Silver Jubilee Medal of 1897, and the Royal Victorian Medal (this, however, is a sort of class of the Royal Victorian Order, for which see KNIGHTHOOD) and the medals awarded for Durbars.

United States.—The war medals and decorations of the United States, although few in number, are interesting, as they are nearly all associated in the American mind with the Civil War.

The principal military decoration of the United States is the "Medal of Honor," which was founded for the reward of unusual bravery or special good conduct during the Civil War. In its present form it is formed of thirty-four stars, with a medallion in the centre bearing a head of Minerva and round it UNITED STATES OF AMERICA in relief. On each ray of the star is an oak-leaf, and the points of of trefol shaped. A laurel wreath, in green enamelled, encircles the whole, and this is surmounted by VALOR, which in turn is surmounted by an eagle that attaches the decoration to its ribbon. This last is blue, with thirteen white stars worked on it in silk. Accompanying this decoration there is a laurel leaf lapel badge, hexagonal, and made of blue silk with the thirteen stars in white.

The original form of the decoration had no encircling wreath; on the rays, instead of the oak-leaves, were small wreaths of laurel and oak, and the design in the central medallion was a figure of Minerva standing, with her left hand resting upon a consul’s fasces and her right warding off with a shield the figure of Discord. The background was surmounted by a trophy of crossed guns, swords, &c., with eagle above, and the ribbon was designed of the national colours, as a laurel leaf streamer, alternated red and white stripes, and across the ribbon at the top a broad black line (palae gifts and argent and a chief azure). The ribbon was attached to the coat by a clasp badge bearing two cornucopias and the arms of the U.S. National defence but has this badge, but is suspended from a concealed bar brooch.

Another special decoration is the "Merit" Medal. This bears on the obverse the inscription VICTORIAE ET AVDACIÆ MONUMENTVM ET PRAEMIVM, and on the reverse the inscription FOR MERIT, surrounded by an oak-leaf wreath; in the upper part of the exergue is UNITED STATES ARMY, in the lower thirteen stars. The ribbon is red, white and blue, in six stripes, two red stripes divided by a fine white line in the centre, two white on either side of the red and two blue forming the outer edge.

We come now to the war medals proper, issued generally to all those who took part in the events commemorated.

The Civil War Medal bears on the obverse the portrait of Lincoln, suspended from a ribbon, and on the reverse a large laurel wreath—WITH MALICE TOWARDS NONE, WITH CHARITY FOR ALL. On the reverse is the inscription THE CIVIL WAR, 1861-1865 surrounded by a wreath of oak leaves and olive branches. The ribbon is somewhat similar to that last described; the blue stripe, however, is in the centre, divided as before by a white line, and the red stripes form the outer edge.

The Island's Medal is interesting from the fact that its reverse was copied on other medals, this making it, in a sense, a "general service" medal. On the obverse is described in Indian war costume bearing a spear, in the upper part of the exergue the Inscription, "The Island’s Medal," and with a color guard and a band of laurel on either side. What we have called the "general service" design on the reverse is composed of (a) an eagle perched on a cannon, surrounded by five oak-leaves (typifying the five great wars of the United States), rifles, Indian shield, spear and arrows, Filipino dagger and Cuban machete; (b) below this trophy the words FOR MERIT. Below, the date 1898, with, on one side of it, a branch of the tobacco-plant, and on the other a sugar-cane. Reverse: As for "Indian Wars" Medal. Ribbon: Centre, golden-yellow, with two red stripes near to the edges, the edges themselves being narrow stripes of blue.

The "Philippine Insurrection" Medal bears on the obverse a combination of tree branches (severity) on the left of the obverse (lightenment), and on the right a balance (representing Justice). This is encircled by the inscription PHILIPPINE INSURRECTION 1899. The ribbon is blue, with two red stripes near the edges. Reverse: As in "Indian Wars" Medal.

Another medal connected with the Filipino insurrection is the so-called "Congressional" Medal, which was designed to commemorate the participation in the war of regiments and volunteers, Northerners and Southerners, side by side. On the obverse is a colour-party of infantry with the national flag, the fly of the flag extending almost to the edge of the medal. Below is the date, 1899, and above is a semicircle, Filipino Insurrection. The ribbon is purple with a narrow black edge, the blue being nearest the edge and the red nearest the centre.

The "China Relief" Medal bears on the obverse a Chinese dragon surmounted by a red cloud, and on the reverse the inscription COMMISSIONED FOR PATRIOTISM, FORTITUDE AND LOYALTY, surrounded by a wreath of oak-leaves (typifying the North) and palm branches (typifying the South). The ribbon is red, with a blue stripe at the edge, and the blue being nearest the edge and the red nearest the centre.

The "Rescue" Medal, in gold or silver, is awarded for bravery in saving life by land or sea.

Other countries.—As has been mentioned above, foreign decorations for military service usually take the form of Orders in many classes. There are, however, numerous long service decorations, which need not be specified. The most famous of the European war and service decorations are the Prussian Iron Cross, the French Médaille Militaire, and the Russian St. George Cross; all these are individual decorations.

The Iron Cross is a German decoration to recipients who have distinguished service in war. It was founded, in the enthusiasm of the War of Liberation movement, on the 10th of March 1813, and revived at the outbreak of the War for Unity against France, 19th of July 1870. The cross is a Maltese cross of cast iron edged with silver. The 1813-15 crosses have the initials F. W. (Friedrich Wilhelm) in the centre, a crown in the upper limb of the cross, and the date (lower). Those of 1870 have W. (Wilhelm) in the centre, crown on the upper and date on the lower limb of the cross.

There are certain distinctions between the Grand Cross, which is worn at the neck, the 1st Class Cross which is worn as an Order suspended from ribbon and bar, and the 2nd Class Cross, which is worn on the breast and consists of a ribbon and medal. In 1870 war medals were given, bearing on the obverse a Maltese cross superposed on a many-pointed star, and having in its centre the Imperial Eagle. The reverse has W. and a crown, with, for combattants and in Der gleichen Heere, and for non-combatants Für Pflichttreue im Kriege, in each case surronded by the words Gott war mit uns Hei se die Ehre. The award is of iron cross, with the rank and file carried on the reverse by the presence of 3-6 months monthly.

MEDEA (Gr. Μήδεα), in Greek legend, a famous sorceress, daughter of Aeetes, king of Colchis. Having been thrown into prison by her father, who was afraid of being injured by her witchcraft, she escaped by means of her art and fled to the temple of Helios the Sun-god, her reputed grandfather. She fell in love with Jason the Argonaut, who reached Colchis at this time, and exacted a terrible revenge for his faithlessness (see ARGAONUTS and JASON). After the murder of Jason's
second wife and her own children, she fled from Corinth in her car drawn by dragons, the gift of Helios, to Athens, where she married king Aegeus, by whom she had a son, Medus. But the discovery of an attempt on the life of Theseus, the son of Aegeus, forced her to leave Athens (Apolloadorus i. 9, 28; Pausanius ii. 3, 6-11; Diod. Sic. iv. 45, 46, 54-56). Accompanied by her son, she returned to Colchis, and restored her father to the throne, of which he had been deprived by his own brother Perses. Medus was regarded as the eponymous hero and progenitor of the Medes. Medea was honoured as a goddess at Corinth, and was said to have become the wife of Achilles in the Elysian fields. The chief seat of her cult, however, was Thessaly, which was always regarded as the home of magic. As time went on her character was less favourably described. In the case of Jason and the Argonauts, she plays the part of a kindly, good-natured fairy; Euripides, however, makes her a barbarous priestess of Hecate, while the Alexandrian writers depicted her in still darker colours. Some authorities regard Medea as a lunar divinity, but the ancient conception of her as a Thessalian sorceress is probably correct. The popularity of the story of Medea in modern times is shown by the large amount of literature on the subject. The original story was probably contained in an old epic poem called Μεδειάς, the authorship of which was ascribed to Pindar of Phocaea. It is given in some length in the fourth Pythian ode of Pindar, and forms the subject of the Argonautica of Apollonius Rhodius. There is a touching epistle (Medea to Jason) in the Heroides of Ovid. Medea is the heroine of extant tragedies of Euripides and Seneca; those of Aeschylus and Ennius (adapted from Euripides) are lost. Neopron of Sicyon and Melanthius wrote plays of the same name. Among modern writers on the same theme may be mentioned T. Corell, F. Grillparzer and M. Cherubini (opera).

The death of Glaucus and the murder of her children by Medea was frequently represented in ancient art. In the famous picture of Tomomachus of Byzantium Medea is deliberating whether or not she shall kill her children; there are copies of this painting in the mural decorations of Herculeanum and Pompeii.

See Léon Mallinger, Médée: étude sur la littérature comparée, an account of Medea in Greek, Roman, middle age and modern literature (1868); and the articles in Durel’s and Sapio’s Dictionnaire des antiquités et Roscher’s Lexikon der Mythologie.

MEDELLIN, a city of Colombia and capital of the department of Antioquia, 150 m. N.W. of Bogota, on a plateau of the Central Cordillera, 4823 ft. above sea-level. Pop. (1906 estimate), 50,000. Medellin, the foundation of which dates from 1674, stands in the valley of the Porce, a tributary of the Cauca, and is reputed to be one of the healthiest as well as one of the most attractive cities of the republic. It has a university, national college, school of mines and other educational institutions, assay-ing and refining laboratories, a public library and a mint. The principal industry of the surrounding country is mining, and gold and silver are exported in considerable quantities. Coffee and hides are also exported, but the trade of the city has been greatly impeded by difficulties of transportation. A railroad from Puerto Berrio, on the Magdalena, was begun many years before the end of the 19th century, but political and financial difficulties interposed and work was suspended when only 43 m. were finished. The completion of the remaining 80 m. was part of a larger scheme proposed in 1906 for bringing the Cauca Valley into railway communication with the national capital. MEDFORD, a seaport of Holland, on the Zuider Zee, the terminus of a branch railway from Hoorn, 123 m. S. Pop. (1903), 3212. Once the capital of West Friesland and a prosperous town, many of its streets and quays are now deserted, though the docks and basins constructed at the end of the 16th and beginning of the 17th centuries could still afford excellent accommodation for many ships. Close to the harbour entrance stands the castle built by Florens V., count of Holland, in 1255. It has been restored, and is used as a court of justice. The

West church, formerly called after St Boniface, the apostle of Germany, was once the richest in Friesland, and belonged from an early date to the cathedral chapter at Utrecht, where, until the Reformation, the pastor of Medemblik had a seat in the cathedral. It contains the tomb of Lord George Murray (q.v.). Among the public buildings are the town-hall (17th century), weigh-house, orphanage, the old almshouse, the house (1613) of the Water Commissioners, and a large building formerly belonging to the admiralty and now used as a state lunatic asylum. There are many interesting brick houses, dating chiefly from the beginning of the 17th century, with curious gables and picturesque ornamentation, carved from oak.

MEDFORD, a city, including several villages, of Middlesex county, Massachusetts, U.S.A., on the Mystic river and Lakes, 5 m. N. by W. of Boston. Pop. (1900), 18,244, of whom 4327 were foreign-born; (1910 census) 23,150. The city is served by the Southern Division and a branch of the Western Division of the Boston & Maine railroad, and is connected with Boston and neighbouring cities by electric railways. The Mystic River, a tidewater stream, is navigable for small craft as far as Medford. The city has many of the attractions and facilities for the preservation of the Metropolltan System. Among the city parks are Hastings, Brooks, Logan, Tufts and Magoun. Within the city limits are some of the oldest and most interesting examples of colonial domestic architecture in America, including the so-called “Craddock House” (actually the Peter Tufts house, built in 1677–1688), the “Wellington House,” built in 1657, and the “Royall House.” The last was built originally by Governor John Winthrop for the tenants of his Ten Hills Farm, and was subsequently enlarged and occupied by Lieut.-Governor John Usher, and by Isaac Royall (1717–1756) and his son, Isaac Royall, Jr. (1732–1781) Medford has a public library of about 35,000 volumes, housed in the colonial residence (reconstructed) of Thatcher Magoun. The city has also a city hall, a high school and manual training school, an open house, and one of the handsomest armory buildings in the country (the home of the Lawrence Light Guard), presented by General Samuel C. Lawrence (b. 1832), a liberal benefactor of Medford institutions and the first mayor of the city (1862–1864). The Salem St. Burying Ground, dating from 1669, is one of the oldest burial places in America. The Medford Historical Society maintains a library and museum in the Mystic River Reservation of the Metropolitan System. Medford is the seat of Tufts College, planned and founded as a Universalist institution in 1852 by Hosea Ballou, its first president, and others, and named in honour of Charles Tufts (1718–1876), a successful manufacturer, who gave the land on which it stands. The college, which had 1120 students and 217 instructors in 1909, comprises a college of letters, a divinity school, and a school of engineering (all in Medford), and medical and dental schools in Boston; it is now independent. Among the twenty college buildings, the Barnum Museum of Natural History (1846) is the most important. The college is financed by the Eaton Memorial Fund (1907), presented by Mrs Andrew Carnegie in memory of her pastor, are noteworthy. The college endowment amounted in 1908 to $2,500,000.

Medford was first settled in 1630. A considerable portion of its area formed the plantation of Matthew Cradock (d. 1641), first governor of the Massachusetts Bay Company, who in 1630

A prominent Loyalist, whose estate was seized during the War of Independence, but was restored to his heirs about 1800. He endowed the first professorship of law in America—at Harvard College.
MEDHANKARA—MEDIA

sent out agents to settle his lands. John Winthrop’s “Ten Hills Farm,” partly within the present limits of Medford, was settled soon afterwards. One of the earliest industries was ship-building, John Winthrop’s “Blessing of the Bay,” built on the Mystic in 1631–1632, being one of the first keels laid on the continent. In 1682 Thatcher Magoun began building sea-going vessels, and many of the famous privateers of the War of 1812 were constructed here. By 1856 Medford employed fully a quarter of all the shipwrights of the state. The industry gradually lost its importance after the introduction of steamships, and the last keel was laid in 1873. Another early industry was the printing of newspapers; this was carried on in the houses, especially by the Hall family and, after about 1850, by the Lawrence family, but was discontinued in 1905. The manufacture of brick and tile was an important industry in the 17th century. The Cradock bridge, the first toll-bridge in New England, was built across the Mystic in 1638; over it for 150 years ran the principal thoroughfare, from Boston to Maine and New Hampshire. The course of Paul Revere’s ride lay through Medford Square and High Street, and within a half-hour of his passage the Medford minute men were on their way to Lexington and Concord, when the American Revolution began. The New England Company’s officers were quartered here for the winter. The Middlesex Canal was opened through Medford in 1803, and the Boston & Lowell railroad (now the southern division of the Boston & Maine) in 1831. Medford was chartered as a city in 1852.

See Charles Brooks, History of the Town of Medford (Boston, 1855; enlarged by J. M. Usber, Boston, 1886); Historical Register of the Medford Historical Society (1889 et seq.); Proceedings of the 250th Anniversary of the Settlement of Medford (Medford, 1905); S. A. Drake, History of Middlesex County (2 vols., Boston, 1880) and Helen Tilden Wild, Medford in the Revolution (Medford, 1903).

MEDHANKARA, the name of several distinguished members, in medieval times, of the Buddhist order. The oldest flourished about A.D. 1200, and was the author of the Viniya Artha Samuccaya, a work in the Sinhalese language on Buddhist canon law. Next to him came Aranāthaka Medhankara, who presided over the Buddhist council held at Polonaruwa, then the capital of Ceylon, in 1320. The third Venaratana Medhankara, flourished in 1380, and wrote a poem in Pali, Jina Cariya, on the life of the Buddha. He also wrote the Parvaka Siddha. The fourth was the celebrated scholar to whom King Parakrama Bahu IV. of Ceylon entrusted in 1397 the translation from Pali into Sinhalese of the Jätaka book, the most voluminous extant work in Sinhalese. The fifth, a Burmese, was called the Sangharaja Nava Medhankara, and wrote in Pali a work entitled the Loka Paḍāpa Sātra, on cosmogony and allied subjects.

See the Journal of the Pali Text Society, 1882, p. 126; 1886, pp. 62, 67, 72; 1890, p. 63; 1896, p. 43; Madhumalata, ch. xi., vols. i. and ii. (T. W. K. D.)

MEDHURST, WALTER HENRY (1796–1857), English Congregationalist missionary to China, was born in London and educated at St Paul’s school. He learned the business of a printer, and having become interested in Christian missions he sailed in 1816 for the London Missionary Society’s station at Malacca, which was intended to be a great printing-press. He became proficient in Malay, in a knowledge of the written characters of Chinese, and in the colloquial use of more than one of its dialects. He was ordained at Malacca in 1819, and engaged in missionary labours, first at Penang, then at Batavia, and finally, when peace was concluded with China in 1824, at Shanghai. There he continued till 1856, laying the foundations of a successful mission. His principal labour for several years, as one of a committee of delegates, was in the revision of existing Chinese versions of the Bible. The result was a version (in High Wen-li) marvellously correct and faithful to the original. With John Strowach he also translated the New Testament into the Mandarin dialect of Nanking. His Chinese-English and English-Chinese dictionaries (each in 2 vols.) are still valuable, and to him the British public owed its understanding of the teaching of Hung-Sew-Tseuen, the leader of the Tai-ping rising (1851–64).

The university of New York conferred upon him in 1843 the degree of D.D. Medhurst left Shanghai in 1856 in failing health, and died two days after reaching London, on the 24th of January 1857. His son, Sir Walter Henry Medhurst (1822–1885), was British consul at Hankow and afterwards at Shanghai.

MEDIA, the ancient name of the north-western part of Iran, the country of the Medes, corresponding to the modern provinces of Azerbaijan, Ardahan, Irak Ajemi, and parts of Kurdistan. It is separated from Armenia and the lowlands on the Tigris (Assyria) by the mighty ranges of the Zagros (mountains of Kurdistan); in its northern parts probably called Chalutras, Plin. v. 98, and in the north by the valley of the rivers (Aras). In the east it extends towards the Caspian Sea; but the high chains of mountains which surround the Caspian Sea (the Parachororatas of the ancients and the Elburz, separate it from the coast, and the narrow plains on the border of the sea (Gilan, the country of the Gelae and Amardi, and Mazandaran, in ancient times inhabited by the Tapuri) cannot be reckoned as part of Media proper. The greater part of Media is a mountainous plateau, about 3000–5000 ft. above the sea; but it contains some fertile plains. The climate is temperate, with cold winters, pleasant summers, and frosty winters. It was probably the cradle and birthplace of the Arians, and the shores of the Caspian, where the mountains are covered with a rich vegetation. Media contains only one river, which reaches the sea, the Sefid Rud (Amaricus), which flows into the Caspian; but a great many streams are exhausted after a short course, and in the north-west is a large lake, the lake of Urmiah or Urmia. From the mountains in the west spring some great tributaries of the Tigris, viz. the Dihula (Gyndes) and the Kurkheh (Choaspes). Towards the south-east Media passes into the great central desert of Iran, which eastwards of Rahgae (mod. Kari, near Teheran), in the region of the "Caspian gates," reaches to the foot of the Elburz chain. On a tract of about 150 m. the western part of Iran is connected with the east (Khorasan, Parthyaea) only by a narrow district (Choarene and Comisene), where human dwellings and small villages can exist. The people of the Mada, Medes (the Greek form Μῆδος is Ionian for Μῆδοι) appear in history first in 836 B.C., when the Assyrian conqueror Sennacherib II. in his wars against the tribes of the Zagros received the tribute of the Amadi (this form, with prothetic η, occurs only here, has many analogies in the names of Iranian tribes). His successors took many expeditions against the Medes (Mada). Sargon in 715 and 713 subjected them "to the far mountain Blinik," i.e. the Elburz (Demavend) and the borders of the desert. They were divided into many districts and towns, under petty local chieftains; from the names which the Assyrian inscriptions mention, we learn that they were an Iranian tribe and that they had already adopted the religion of Zoroaster. In spite of different attempts of some chieftains to shake off the Assyrian yoke (cf. the information obtained from prayers to the Sun-god for oracles against these rebels: Kudur-azzur, Assyrische Gebete an den Semmengott), Media remained tributary to Assyria under Sargon's successors, Sennacherib, Esar-haddon and Assur-bani.

Herodotus, i. 101, gives a list of six Median tribes (γενά), among them the Paracetaceni, the inhabitants of the mountainous highland of Paracetacene, the district of Isahan, and the Mogol, i.e. the Magians, the hereditary caste of the priests, who in Media took the place of the "fire-kindlers" (αὐθαίρετοι) of the Zoroastrian religion, and who spangled from Media to Persia and to the west. But the Iranian Medes were not the only inhabitants of the country. The names in the Assyrian inscriptions prove that the tribes in the Zagros and the northern parts of Media were not Iranians nor Indo-Europeans, but an aboriginal population, like the early inhabitants of Armenia, perhaps connected with the numerous tribes of the Caucasus. 1

1 Anc. Mammian, Strabo xi. 529; Martiane, Ptol. vi. 2, 5, probably identical with the name Matiane, Matiene, by which Pliny i. 180, 202, iii. 94, v. 4, 92 (in 1. 72 and 73 they seem to be a different people in Asia Minor); Polyb. v. 44, 9; Strabo i. 49, ii. 73, xi. 509, 514, 523, 525; Plin vi. 48, designate the northern part of Media.
We can see how the Iranian element gradually became dominant. princes with Iranian names occasionally occur as rulers of these tribes. But the Gelaec, Tapuri, Cadusii, Amardi, Utti and other tribes in northern Media and on the shores of the Caspian were not Iranians. With them Polybius v. 44, 9, Strabo xi. 507, 508, 514, and Pliny vi. 46, mention the Anarisci, whom they consider as a particular tribe; but in reality their name, the "Not-Arians," is the comprehensive designation of all these small tribes.

In the second half of the 7th century the Medians gained their independence and were united by a dynasty, which, if we may trust Herodotus, derived its origin from Deioeces (q. e.), a Median chieftain in the Zagros, who was, with his kinsmen, transported by Sargon to Hamath (Hamah) in Syria in 715 B.C. The kings, who created the Median Empire, were Phraortes and his son Cyaxares. Probably they were chieftains of a nomadic Median tribe in the desert, the Manda, mentioned by Sargon; for the Babylonian king Nabonidus designates the Medians and their kings always as Manda. The origin and history of the Median Empire is quite obscure, as we possess almost no original information, and not a king's name, or inscription from Media itself. Our principal source is Herodotus, who wrongly makes Deioeces the first king and uniter of the whole nation, and dates their independence from c. 710—i.e. from the time when the Assyrian supremacy was at its height. But his account contains real historical elements, whereas the story which Ctesias gave (a list of nine kings, beginning with Arbaces, who is said to have destroyed Nineveh about 880 B.C., preserved in Diod. ii. 32 sqq. and copied by many later authors) has no historical value whatever, although some of his names may be derived from local traditions. According to Herodotus, the conquests of Cyaxares were interrupted by an invasion of the Scythians, who founded an empire in western Asia, which lasted twenty-eight years. From the Assyrian prayers to the Sun-god, mentioned above, we learn that the Median dynasts, who tried rebellions against the Assyrians in the time of Esar-haddon and Assur-bani-pal, were allied with chieftains of the Cimmerians (who had come from the northern shore of the Black Sea and invaded Armenia and Asin Minor), of the Sapardas, Ashguzu and other tribes; and from Jeremiah and Zephaniah we know that a great invasion of Syria and Palestine by northern barbarians really took place in 626 B.C. With these facts the traditions of Herodotus must in some way be connected; but at present it is impossible to regain the history of these times. The only certain facts are that in 666 Cyaxares succeeded in destroying Nineveh and the other cities of Assyria (see PHAORTES AND DEIOECES).

From then the Median king ruled over the greatest part of Iran, Assyria and northern Mesopotamia, Armenia and Cappadocia. His power was very dangerous to their neighbours, and the exiled Jews expected the destruction of Babylonia by the Medes (Isa. xiii., xiv., xx.; Jerem. i. 11). When Cyaxares attacked Lydia, the kings of Cilicia and Babylon intervened and negotiated a peace in 585, by which the Halys was established as the boundary. Nebuchadrezzar married a daughter of Cy- xares, and an equilibrium of the great powers was maintained till the rise of Cyrus.

About the internal organization of the Median Empire we know only that the Greeks derive a great part of the ceremonial of the Persian court, the costume of the king, &c., from Media. But it is certain that the national union of the Median clans was the work of their kings; and probably the capital Ecbatana (Ecbatana) was founded by them. By the rebellion of Cyrus, king of Persia, against his suzerain Astyages, the son of Cyaxares, in 553, and his victory in 550, the Medes were subjected to the Persians. In the new empire they retained a prominent position; in honour and war they stood next to the Persians; the ceremonial of their court was adopted by the new sovereigns who in the summer months resided in Ecbatana, and many noble Medes were employed as officials, satraps and generals. After the assassination of the usurper Smerdis, a Mede Fravartish (Phraortes), who pretended to be of the race of Cyaxares, tried to restore the Median kingdom, but was defeated by the Persian generals and executed in Ecbatana (Darius in the Behistun inscr.). Another rebellion, in 409, against Darius II. (Xenophon, Hellen. i. 2, 19) was of short duration. But the non-Aryan tribes of the north, especially the Cusadians, were always troublesome; many abortive expeditions of the later kings against them are mentioned.

Under the Persian rule the country was divided into two satrapies. The south, with Ecbatana and Rhagae (Rai), Media proper, or "Great Media," as it is often called, formed in Darius' dominions an eleventh satrapy (Herodotus iii. 92), together with the Parthians and Orontes Medes; the north, the district of Matiane (see above), together with the mountainous districts of the Zagros and Assyria proper (east of the Tigris) was united with the Alarodians and Sasprians in eastern Armenia, and formed the eighteenth satrapy (Herod. iii. 94; cf. v. 49, 52, vii. 72). When the empire decayed and the Carduchi and other mountainous tribes made themselves independent, eastern Armenia became a special satrapy, while Assyria seems to have been united with Media; therefore Xenophon in the Amst. ii. 4, 27; iii. 5, 15; vii. 8, 25, cf. iii. 4, 8 sqq. always designates Assyria by the toponym Assyria Cappadocica.

Alexander occupied Media in the summer of 330; in 328 he appointed Atropates, a former general of Darius (Arrian iii. 8, 4), as satrap (iv. 18, 3, vi. 20, 9), whose daughter was married to Perdiccas in 324 (Arrian viii. 4, 5). In the partition of his empire, southern Media was given to the Macedonian Peithon; but the north, which lay far off and was of little importance for the generals who fought for the inheritance of Alexander, was left to Atropates. While southern Media with Ecbatana passed to the reign of Antigonus, and afterwards (about 310) to Seleucus I.; Atropates maintained himself in his satrapy and succeeded in founding an independent kingdom. Thus the partition of the country, which the Persian had introduced, became lasting; the north was named Atropatene (in Plin. vii. 42, Atrapatene; in Ptolem. vi. 2, 5, Tropatene; in Polyb. v. 44 and 55 corrupted in τά σαραπεία καλωμένα), after the founder of the dynasty, a name which is preserved in the modern Azerbaijan; cf. Nölsche, "Atropatene," in Zeitschrift der deutschen morgen. Gesellschaft, 34, 652 sqq. and Marquart, Ernanzehir, p. 128 sqq. The capital was Gazara in the central plateau of Media, near modern Sis. (cf. Arrian, xix. 26; Plut. Anton. 38; Ptol. iii. 2, 10) or Vera (Strabo xi. 533), probably identical with the great ruin Tahti Suleiman, with remains of Sassanian fire-altars and of a later palace. The kings had a strong and warlike army, especially cavalry (Polyb. v. 55; Strabo xi. 533). Nevertheless, King Artabazanes was forced by Antiochus the Great in 220 to conclude a disadvantageous treaty (Polyb. v. 52), and in later times the rulers became in turn dependent on the Parthians, on Tigranes of Armenia, and in the time of Pompey who defeated their king Darius (Apian, Milth. 106), on Antonius (who invaded Atropatene) and on Augustus of Rome. In the time of Strabo (A.D. 17), the dynasty existed still (p. 523); in later times the country seems to have become a Parthian province.

Atropatene is that country of western Asia which was least of all influenced by Hellenism; there exists not even a single coin of its rulers. But the opinion of modern authors—that it had been a special refuge of Zoroastrianism—is based upon a wrong etymology of the name (which is falsely explained as "country of fire-worship"), and has no foundation whatever. There can be no doubt that the kings adhered to the Persian religion; but it is not probable that it was deeply rooted among their subjects, especially among the non-Aryan tribes.

Southern Media remained a province of the Seleucid Empire for a century and a half, and Hellenism was introduced everywhere. "Media is surrounded everywhere by Greek towns, in pursuance of the plan of Alexander, which protect it against the neighbouring barbarians," says Polybius (x. 27). Only Ecbatana retained its old character. But Rhagae became a Greek town, Euporus; and with it Strabo (xi. 524) names Laodicea, Apamea, Heraclea or Achaias (cf. Plin. viii. 48). Most of them were founded.
by Seleucus I. and his son Antiochus I. In 221, the satrap Molon tried to make himself independent (there exist bronze coins with his name and the royal title), together with his brother Alexander, satrap of Persis, but they were defeated and killed by Antiochus the Great. In the same way, in 161, the Median satrap Timarchus took the diadem and conquered Babylonia; on his coins he calls himself "the great king Timarchus"; but the legitimate king, Demetrius I., succeeded in subduing the rebellion, and Timarchus was slain. But with Demetrius I. the dissolution of the Seleucid Empire begins, which was brought on chiefly by the intrigues of the Romans, and shortly afterwards, about 150, the Parthian kings, Mithradates I. (q.v.), conquered Media (Justin xli. 6). From this time Media remained subject to the Arsacids, who changed the name of Rhagae, or Europus, into Arsacia (Strabo xi. 324), and divided the country into five small provinces (Isidorus Charac.). From the Arsacids or Parthians, it passed in A.D. 226 to the Sassanids, together with Atropatene. By this time the old tribes of Aryan Iran had lost their character and had been amalgamated into the one nation of the Iranians. The revival of Zoroastrianism, which was enforced everywhere by the Sassanids, completed this development. It was only then that Atropatene became a principal seat of fire-worship, with many fire-altars. Rhagae now became the most sacred city of the empire and the seat of the head of the Zoroastrian hierarchy; the Sassanid Avesta and the tradition of the Parsees therefore consider Rhagae as the home of the family of the Prophet. Henceforth the name of Media is used only as a geographical term and begins to disappear from the living language; in Persian traditions it occurs under the modern form Māh (Armen. Mai; in Syriac the old name Modai is preserved; cf. Marquart, Eranoshar, 18 seq.).

For Mahommedan history see CALIPHATE; for later history SELJUKS and PERSIA.       (Ed. M.)

MEDIATION (Lat. mediatus, middle), in the international sense, the intervention of a third power, on the invitation or with the consent of two other powers, for the purpose of arranging differences between the latter without recourse to war. Mediation may also take place after war has broken out, with a view to putting an end to it on terms. In either case the mediating power negotiates on behalf of the parties who invoke or accept its aid, but does not go farther. Unlike an arbitrating power the mediator limits his intervention to suggestion and advice. His action is liable to be arrested at any time at the will of either party unless otherwise agreed, in which case to arrest it prematurely would be a breach of good faith. The difference between mediation and arbitration may be stated in the words of the Digest (lib. iv. tit. 8, § 13): "Receipisse autem arbitrium videtur, ut ait Pedius, qui judicibus partes suscipit finemque se sua sententia controversiis impositum polluitur. Quod si hactenus intervenit ut exerpertur in concilio suo vel auctoritate discutiat litem paternetur, non videtur arbitrium recepisse." Some writers distinguish mediation from "good offices," but the distinction is of little practical value. We may, if we please, regard "good offices" as inchoate mediation, and "mediation" as comprising the latter plus the former. Thus we may say that a third power renders "good offices" if it brings the parties together so as to make diplomatic negotiations between them possible; whilst if it takes an active part in those negotiations it becomes for the time being a mediator. The spontaneous yet successful effort made by President Roosevelt in 1905 to bring together the Russian and Japanese governments, and to secure their appointing delegates to discuss terms of peace, although not strictly mediation, was closely akin to it. Of successful mediation in the strict sense there have been many instances: that of Great Britain, in 1875, between Portugal and Brazil; of France, in 1849-1850, when differences arose between Great Britain and Greece; of the Great Powers, in 1868-1869, when the relations of Greece and Turkey were strained to breaking-point by reason of the insurrection in Crete; of Pope Leo XIII., in 1885, between Germany and Spain in the matter of the Caroline Islands. In these cases mediation averted war. The Austro-Prussian War of 1866, the war between Chile and Peru in 1882, and that between Greece and Turkey in 1897, are instances of wars brought to a close through the mediation of neutral powers. Mediation has also been occasionally employed where differences have arisen as to the interpretation of treaties or as to the mode in which they ought to be carried out; as when Great Britain mediated between France and the United States with regard to the Treaty of Paris of the 4th of July 1830. In one case at least mediation has been successful after a proposal for arbitration had failed. In 1844, when war between Spain and Morocco was threatened by reason of the frequent raids by the inhabitants of the Rif on the Spanish settlement of Ceuta, Spain declined arbitration on the ground that her rights were too clear for argument. But both she and Morocco subsequently accepted joint mediation at the hands of Great Britain and France. The cause of mediation was considerably advanced by the Declaration of Paris of 1856. The plenipotentiaries of Great Britain, France, Austria, Russia, Sardinia and Turkey recorded in a protocol, at the instance of Lord Clarendon, their joint wish that "states between which any misunderstanding might arise should, before appealing to arms, have recourse so far as circumstances might allow (en tant que les circonstances l'admettraient) to the good offices of a friendly power." Article 8 of the Treaty of Paris, concluded in the same year, stipulated that if there should arise between the signatories of the Convention the other signing powers any misunderstanding which might endanger the maintenance of their relations, the Porte and each of such powers, before having recourse to the use of force, shall afford the other contracting parties the opportunity of preventing such as extremity by means of mediation." These precedents (in which it will be seen that "good offices" and "mediation" are used interchangeably) were followed in the general act agreed to at the Conference held at Berlin in 1884-1885 the object of which was to secure religious and commercial liberty and to limit warlike operations in the Congo basin. A special form of mediation was proposed by a delegate from the United States at the Peace Conference held at the Hague in 1899, and was approved by the representatives of the powers there assembled. The clause in which this proposal was embodied provided in effect that, whenever there is danger of a rupture between two powers, each of them shall choose a third power to which these differences shall be referred, and that, pending such reference, for a period not exceeding thirty days (unless the time is extended by agreement) the powers at dispute shall assemble and negotiate with each other and leave the dispute entirely in the hands of the mediating power. The powers thus appealed to occupy a position analogous to that of seconds in a duel, who are authorized to arrange an "affair of honour" between their principals. This novel device has the advantage of taming down, if not of eliminating, personal and national prejudices by which controversy is frequently embittered. It also gets over the difficulty, often met with in arbitration, of choosing a referee satisfactory to both parties. The closer the relations between states become, the more their commercial interests are intertwined, the larger the part which mediation seems destined to play. It is true that states which have accepted the intervention of a mediator remain free to adopt or reject any advice he may give, but the advice of a disinterested power must always add considerable moral weight to the side towards which it inclines.       (M. H. C.)

MEDIATIZATION (Ger. Mediatisierung, from Lat. mediatus, mediate, middle), the process by which at the beginning of the 17th century, a number of German princes, hitherto sovereign as holding immediately of the emperor, were deprived of their sovereignty and mediatized by being placed under that of other sovereigns. This was first done on a large scale in 1603, when by a recess of the imperial diet many of the smaller fiefs were mediatized, in order to compensate those German princes who had been forced to cede their territories on the left bank of the
Rhine to France. In 1866 the formation of the Confederation of the Rhine involved an extension of this mediatizing process, though the abolition of the empire itself deprived the word "mediatization" of its essential meaning. After the downfall of Napoleon the powers were besieged with petitions from the mediatized princes for the restoration of their "liberties"; but the congress of Vienna (1814) further extended the process of mediatization by deciding that certain houses hitherto immediate (i.e., Salm, Isenberg, Leyen) should only be represented mediately in the diet of the new Confederation. On the other hand, at Aix-la-Chapelle (1818) the powers, in response to the representations of the aggrieved parties, admonished the German sovereigns to institute a state system of education in Germany that should conform to their wishes as to the instruction given to their young. Of these rights, which included the hereditary right to a seat in the estates, the most valued is that of Ebenbürtigkeit (equality of birth), which, for purposes of matrimonial alliance, ranks the medicated princes with the royal houses of Europe.

See August Wilhelm Hefter, Die Sonderrechte der Soveränen und der Mediatisierten, vormals reichsständischen Häuser Deutschlands (Berlin, 1871). The medicated families are included in the Almanach de Gotha.

MEDICAL EDUCATION. Up to 1838 each University, Royal College of Physicians or of Surgeons, and Apothecaries' Great Hall in Great Britain and Ireland laid down its own regulations for study and examination, and granted its degree or licence without any State supervision. In that year, pursuant to the Medical Act 21 & 22 Vict. c. 90, the General Medical Council of Medical Education and Registration was established, consisting of twenty-three members, of whom seventeen were appointed by the various licensing bodies and six by the Crown. This number was increased by the amended act of 1886 to twenty-nine, three of the six additional members being elected by the profession. By the 21 & 22 Vict. c. 90, the act was "to enable persons requiring medical aid to distinguish qualified from unqualified practitioners." To this end the "Medical Register" was established, on which no person's name could be inscribed who did not hold a diploma or licence from one or more of the licensing bodies after examination. By the 1886 act a qualifying examination was defined as "an examination in medicine, surgery, and midwifery," conducted by universities or by medical corporations, of which one must be capable of granting a diploma in medicine, and one in surgery. The Council is authorized to require the passing of a prescribed number of examinations, both written and oral, and also as to the requisites for obtaining qualifications; and to visit and inspect examinations either personally or by deputy. If the visitors think the course of study and examination of any licensing body is not sufficient to ensure that candidates obtaining its qualification possess the requisite knowledge and skill for the efficient practice of their profession the Council, on a report being made, may represent the same to the Privy Council. The Privy Council may, if it sees fit, deprive the accused body of its power to grant registrable certificates. From this statement it will be seen that the powers of the Council are limited; nevertheless, by their cautious application, and by the loyal manner in which the licensing bodies have acted on the recommendations and suggestions which have from time to time been made, the condition of medical education has been improved; and although there is not a uniform standard of examination throughout the United Kingdom, the Council has ensured that the minimum requirements of any licensing body shall be sufficient for the production of trustworthy practitioners.

One of the first subjects to which the Council applied itself was the establishment of a system of examinations in general knowledge. Such examinations have to be passed before beginning medical study. On presentation of a certificate to the registrars of the Council, and on evidence being produced that the candidate is sixteen years of age, his name is inscribed on the "Students' Register." The subjects of examinations are: (a) English language, including grammar and composition (marks not exceeding 5% of the total obtainable in this section may be assigned to candidates who show a competent knowledge of any named foreign language); (b) anatomy, physiology, and translation from specified authors, and translation of easy passages not taken from such authors; (c) mathematics, comprising arithmetic; algebra, as far as simple equations inclusive; geometry, the subject-matter of Euclid, Books I., II. and III., with easy deductions; (d) one of the following optional subjects—Greek, French, German, Italian, or any other modern language. Certificates are accepted from all the universities of Great Britain and Ireland, from the leading Indian and colonial universities, from government examination boards, and from various other bodies, e.g., the certifying bodies of the gymnasium and real-gymnasium, the French diplomas of Bachelier es Lettres and Bachelier es Sciences, and corresponding entrance examinations to other continental universities are also accepted.

As regards professional education, the Council divided its resolutions into "requirements" and "recommendations"; the former consisting of demands on the licensing bodies, non-compliance with which renders them liable to be reported to the Privy Council; the latter are regarded merely as suggestions for the general conduct of education and examination. The requirements may be summarized as follows: (i) General examination: a course of study between the date of registration and the date of the final examination for any diploma entitling the holder to be registered under the Medical Acts. (c) In every course of medical examination the student shall be required to be conversant with the constitution and chemistry of the human body, and be able to state the various instruments and apparatus for use for examination, and the rudiments of heat, light and electricity; (ii) chemistry, including the principles of the science, and the details necessary for the study of medicine; (iii) elementary biology; (iv) anatomy; (v) physiology; (vi) materia medica and pharmacy; (vii) pathology; (viii) therapeutics; (ix) medicine, including medical anatomy and clinical medicine; (x) surgery, including surgical anatomy and clinical surgery; (xi) obstetrics and gynaecology; (xii) diseases peculiar to women and to new-born children; (xiii) theory and practice of vaccination; (xii) forensic medicine; (xiv) hygiene; (xv) mental disease. (d) The first of the foregoing must be passed at a school or schools of medicine recognized by any of the licensing bodies; provided that the first year may be passed at a university or teaching institution where the subjects of physics, chemistry and biology are taught; and that graduates in arts or science of any university recognized by the Council, who shall have spent a year in the study of these subjects, and have passed in them, shall be held to have completed the first of the five years of medical study. (e) The second year of the same kind must be conducted in a hospital for five months, at least three of which months are to be spent in the practice of medicine; (f) The third year must be conducted for a year of six months, at least a part of which must be passed at a university. The fourth year is to be devoted to a system of general clinical instruction, being such as is approved by the Privy Council. (g) The fifth year of study is intended to be devoted to clinical work and may be passed at any one or more public hospitals or dispensary in respect of clinical instruction: not only is the student examined six months of this year may be passed as a pupil to a practitioner possessing such opportunities of imparting practical knowledge as shall be satisfactory to the medical authorities. This latter method is rarely employed. The "recommendations" of the Council contain suggestions which may or may not be acted on by the bodies. For the most part they are complied with in connexion with the system of practical and clinical teaching.

The Council satisfies itself that its requirements are acted on, and that the examinations are "sufficient," by cycles of inspection about every five years. The inspection of each licence granted annually is visited by an inspector, who forwards his report to the Council, which sends each report to the body for its information and remarks. As yet it has never been the duty of the Council to report to the Privy Council when any examination is insufficient.

Most universities exact attendance at more classes than the colleges and halls; for instance, botany and natural history are taught to their students, who are examined in the subject. The system of professional education is fairly uniform. Since 1875 attendance on "practical" classes has been called for in all subjects. Under this system the larger classes in the sciences are taught systematically; the examinations of the students are taught the use of apparatus and the employment of methods of investigation and observation. Tutorial instruction is superfluous, imposed on teaching by lecture. Much the same pupils who are examined at the bedside by the lecturer, but he receives, either from the house-surgeon or house-physician or from a specially appointed clinical
MEDICAL EDUCATION

Tutor, an insight into methods of examination of diseases, and learns practically the use of the stethoscope and other aids to diagnosis and of surgical and obstetrical instruments. In fact, it may be said that each subject of instruction is duplicated. If this is taken into account, it may be said that the student is fully occupied and the belief is rapidly growing that five years is too short a period of study. As a matter of fact, the average time taken to obtain a British licence to practise is upwards of six years. The probability is that the rapidly increasing specialization will bring in the inclusion of such subjects as physics, biology and chemistry in a "preliminary scientific" examination, which may have to be undertaken before registration as a medical student, thus leaving the whole five years to be devoted to purely professional study.

The German regulations in regard to professional study are so few that they are claimed for the Staats Examen, for which the university degree is no longer necessary. The regulations for the admission of candidates to the Staats Examen are contained in the royal proclamations of the 22nd of June 1833. They comprise: (a) Certificate of a course of study at a classical gymnasium of the German Empire. In exceptional cases, the same from a classical gymnasium outside the German empire may be considered sufficient. (For details of the course of study and examinations, see Minutes of the Genera Medical Council, vol. xxvii. appendix 3.) (b) Certificate from a university, certifying a course of medical study of at least nine half-years at a university of the German empire. (c) Certificate that the candidate has passed, entirely at a German university, the medical Vorprüfung, and thereafter has attended for at least four half-years the medical studies of a university. (d) The special testimony of the clinical directors bearing witness that the candidate has taken part as Praktikant (clerk or dresser) during two half-years at the medical, surgical, and gynaecological clinics; has himself delivered two cases of labour in the presence of his teachers or assistant physicians; and has attended for a half-year as Praktikant the clinic for diseases of the eye.

The medical Vorprüfung referred to is necessary alike for the Staats Examen and the degree of Doctor of Medicine. It takes place at the end of the second year (fourth semester), and includes the subjects of experimental physics, chemistry, botany, zoology, anatomy and physiology. It is conducted by a board appointed yearly by the Minister of Education.

No one can practise medicine in France who does not possess the diploma of Doctor of Medicine of a French university. The qualification of Officier de santé is no longer granted.

France. Before he can inscribe as a student of medicine the applicant must have obtained the diplomas of Bachelier à lettres and Bachelier en arts. Although the courses required for professional study may be completed in four years, a longer time is generally taken before the student proceeds to the final examination for the doctor's degree. Each year is divided into four trimestres; at each trimestre the student must make a new inscription. The trimestres are (1) November and December, 56 days; (2) January, February, March, 86 days; (3) April, May, June, 86 days; (4) July, August, 56 days. Practically there are no regulations determining the division of the various subjects, or the number of lectures in each course, or requiring the student to attend the courses. The medical faculty of each university puts before the students a scheme recommending a Division des études (Division des études) for each of the four years of the medical course, and, as a matter of fact, this order of study is enforced by the system of intermediate examinations (Examen du fin d'année). All the lecture courses are free, as also are the clinics and the hospital service, and there is no system of ascertaining the regularity of attendance at lectures, or of certificate of attendance. If, however, the student fails to pass the Examen du fin d'année he is debarred from making the next trimestral inscription, and thus the course is prolonged. The lectures are, however, closely attended. In connection to the freedom in regard to attendance on systematic lectures, there are strict direction and control in regard to hospital attendance and practical courses. The student is required to sign a register ad locum each time he goes in and out. From the beginning of the third year, e.g. from the ninth quarterly inscription, hospital attendance is enforced till the end of the fourth year. No one can renew his trimestral inscription without producing a schedule of his last trimestral stage, showing that during it he had not absented himself more than five times without explanation. Practical work is obligatory during each of the four years. Systematic courses of lectures, Conférences are held by the assistant-professors (agrégés) in natural history, physiology, general pathology, internal pathology, external pathology. At the end of the first year the student is examined in osteology, myology and the elements of the use of the physical thermometer. In the second year, anatomy and physiology in all their branches; at the end of the third year, in medicine and surgery; at the end of the fourth year, an examination is held over the whole field of study.

No one is allowed to enter on the study of medicine without passing the Artium Examen of a secondary school. This is the reason why the study of the German Examen in the University of a classical gymnasium. After study for two semesters an examination must be passed in psychology, logic and history. The special professional examinations consist of (1) preliminary scientific, in botany, zoology, physics, chemistry; (2) first special or professional, anatomy (orally and by dissections), physiology, and pharmacology; (3) second special or professional, written examinations in medicine, surgery, medical jurisprudence; practical and oral in operative surgery, in clinical medicine, and clinical surgery; and oral in pathological anatomy, medicine, and its application; (4) a number of additional subjects. The completion of the full medical course takes six years, of which the first two are devoted to the study of the natural sciences.

Authorities. The history of the development of medical education from the earliest times down to 1894 will be found treated of generally in Puschmann's Geschichte des medizinischen Unterrichts in England, 1894-1896 translated by E. H. Hare (London, 1899). Those desiring more special information on the subject in regard to the details of British institutions should consult the annals of the various universities and colleges of Great Britain and Ireland. The following works supply much interesting information regarding the gradual rise and development of teaching and examination: Annals of the Barber Surgeons, by Sydney Young (1890); History of the Royal College of Surgeons in Ireland, by Percy (1890); Early Days of the Royal College of Physicians of Edinburgh, by Peel Ritchie (1889); Historical Sketch of the Royal College of Surgeons of Edinburgh, by Gardiner (1886); Memoirs of the Faculty of Physicians and Surgeons of Glasgow, by Duncan (1896); The Story of the University of Edinburgh, by Sir A. Grant (1884); University of Glasgow, by Stewart (1891).

As late as 1880 medical education in the United States was in a deplorable condition. In the early history of the country, before and shortly after the beginning of the 19th century, the few medical colleges had shown a disposition to stimulated those who entered upon their courses, and some effort was made, through the agency of state boards, to control the licence to practise. But as the country increased in population and wealth preliminary requirements were practically abolished, the length of the courses given each year was shortened to four or five months or less, and in the second and final year there was simply a repetition of the courses given during the first year. This is to be attributed mainly to the fact that there was no general national or state supervision of medical training. Medical colleges could obtain incorporation under state laws without difficulty, and brought considerable advantages in the way of prestige and increased practice to those concerned. That the existence of a college depended solely upon the fees of the students encouraged the tendency to make both entrance and graduation requirements as easy as possible, especially as there was no state supervision, and the mere possession of a diploma entitled the holder to practise. Fortunately, during this period the practical character of the clinical instruction given in the better colleges fitted the graduates in some measure for the actual necessities of practice, while the good traditions of medicine as a learned profession stimulated those who adopted it as a career, so that in the main the body of practitioners deserved and held the confidence and respect of the community. From the middle of the 19th century there has been constant agitation on the part of the physicians themselves for an improvement in medical education. The first notable result was an increase in the time of instruction from two to three years (Chicago Medical College, 1859; Harvard Medical School, 1871), the lengthening of each session to six
months or more, and the introduction of graded courses instead of a repetition of the same lectures every year. The improvement thus begun became marked during the decade 1860–1900, amounting almost to a revolution in the rapidity with which the course of instruction was amplified. Many factors co-operated to produce this result: the general development of scientific instruction in the colleges and secondary schools, the influence of the large number of medical graduates who completed their training by study in European countries; the adoption by many states of stringent regulations regarding the licence to practice within their borders, the good examples set by many leading schools in voluntarily raising their requirements for entrance and graduation, and, perhaps above all in its general effect, the agitation continually maintained by several national or state associations which in a measure have exerted the general regulating control that in other countries has been enforced by national legislation. Among the most influential of these associations are the American Medical Association, the American Institute of Medicine, the Association of American Medical Colleges, the Illinois State Board of Health, and the University of the State of New York.

The different states make their own general regulations as to the practice of medicine within their borders. Certain states recognize the medical diplomas granted by other states having equivalent standards of examination. Such certificates are generally required to be (a) of graduation from a "reputable medical school," (b) of moral character, (c) the applicant must be at least twenty-one years of age. These rules enable the candidate to prepare himself before the state board for the state examination. In many states the applicant must satisfy the board not only as to his professional, but as to his general education. The standing of the various medical schools is usually looked to by the state boards, each one determining the matter for its own state, consequently a school may confer a degree recognized as reputable in several states but not in others. Only three or four states regulate the chartering of institutions. In other states any body of men may secure articles of incorporation of a college or school by paying the necessary state fee, without question as to the ability of the incorporators. The practice, however, has been the growth of American public opinion that a four-years' course of medical training has become the standard in medical schools, and in the majority this is in addition to one or two years' training in the natural sciences. There are some sixty-five state boards, and many have adopted strong medical practice acts.

The standard of preliminary requirements for entrance to the medical schools is being gradually raised, and a large number of the leading medical schools of the country are in the colleges comprising the Association of Medical Colleges, which numbers more than half the American medical schools, accept as an entrance standard a certificate of at least one year's study at a high school. In the report for 1908 of the United States bureau of education of 71 schools, which report the number of their students having an arts degree, it is stated that a degree was held by only 15% of the candidates in medicine. These students were mostly distributed between the Johns Hopkins Medical School (which at the time of its foundation in 1893 had only admitted college graduates), and has in addition stipulated that candidates shall have a knowledge of all branches of medical and surgical practice of the time. In the course, which must include French and German, together with physics, chemistry and biology. This tendency is in accordance with the recommended standard of medical education suggested by the Council of Medical Education of the American Medical Association, of which the following is a summary:—

1. Preliminary of a four-years' high school education or an examination such as would admit to a recognized university.

2. Previous to entering a medical college every student should receive from the state board a "medical student's entrance certificate" to be given on the production of credentials of training as above.

3. Four years of study in a medical college having a minimum of a 30-weeks' course each year, with not less than 30 hours' work per week.

4. A satisfactory examination from college to entitle a candidate to present himself for examination before a state board.

Practically all medical schools admit women, but there are three separate schools of medicine for women: The Women's Medical College of Philadelphia, Pennsylvania; Women's Medical College, Baltimore, Maryland; New York Medical College and Hospital for Women—the last the only one of the eighteen homoeopathic colleges of the United States.

MEDICAL JURISPRUDENCE, or FORENSIC MEDICINE, is that branch of state medicine which treats of the application of medical knowledge to certain questions of civil and criminal law. The term "medical jurisprudence," though sanctioned by long usage, is not really appropriate, since the subject is strictly a branch of medicine rather than jurisprudence; it does not properly include sanitation or hygiene, both this and medical jurisprudence proper being distinct branches of state medicine. The connexion between medicine and law was perceived long before medical jurisprudence was recognized, or had obtained a distinct appellation. It first took its rise in Germany, and more tardily received recognition in Great Britain. Forensic medicine, or medical jurisprudence proper as distinguished from hygiene, embraces all questions which bring the medical man into contact with the law, and embraces (1) questions affecting the civil rights of individuals, and (2) injuries to the person.

1. Questions Affecting the Civil or Social Rights of Individuals.

1. Development of the Human Frame.—The development of the physical and mental powers of the human being is a factor of prime importance in determining the consequences of crime, in the determination of criminal responsibility, in the exercise of civil responsibility, or the power of giving validity to civil contracts, and in determining the personal identity of a living person or of a corpse. Human life is usually divided into the five periods of infancy, childhood, youth, manhood and old age. Some writers increase the number of these unnecessarily to seven periods. "Infancy" is the period from birth till the first or milk set of teeth begin to be shed—usually about the seventh year. During this time the body is in size and stature more, relatively, than at any other period of existence; and the mental faculties undergo great development. The milk teeth, twenty in number, are evolved in the first five years of life, with the exception of two, which do not appear until after the age of five, and with the exception of one, which may not appear till after the age of seven. The teeth, which are shed, are replaced by the second or permanent set, thirty-two in number, though three or four may be missing. The mammaries are not developed until this period. Marked differences between the probity of the sexes are noticeable even at an early period of childhood, and long before the characteristic functions begin to be developed.
Youth is marked at its commencement by the changes which occur at puberty—the development of the generative organs, in both sexes, the appearance of hair on the genitals, the appearance of a beard in the male, the development of the breasts in the female, the appearance of the monthly flow in the female, and the ability to become pregnant. The changes in the male. Marked mental changes now occur and the generative functions are perfected. Youth terminates at the age of legal majority, twenty-one years, or perhaps the period outlives to be extended to twenty-five years of age, as it is with some nations.

Mankind (or Womanhood) is the period of perfection of all the bodily and mental powers. It ceases in woman with the cessation of the monthly flow at about forty-five years of age; but in man it often extends to a much later period of life. Old Age begins with the decay of the bodily and mental faculties, and dates from the first appearance of wrinkling on the skin, the whitening of the hair, and feebleness of the limbs. In its later stages decay of the mental faculties, deafness, obscurity or loss of vision, and bowing of the spine are added.

2. Duration of Human Life.—The changes of human life form an important subject of inquiry, and on deductions from comparisons of birth and death rates is founded the system of annuities, insurance against loss in sickness, and the insurance of lives. Since the establishment of compulsory registration of deaths, our knowledge of the ordinary and extraordinary chances of human life has been extended, and surer data are available for calculations of probabilities of life, of survivorships, and of the payments which ought to be made in benefit clubs (see Insurance).

3. Personal Identity.—Where the identity has to be established or disproved after long absence, evidence to foreign climates and habits, of sounds, &c., the problem has often been extremely difficult. Data for identifying a person are individual and family likeness, stature, the colour of the eyes, peculiarities of garb and manner, recollection of antecedent events, but more especially marks on the persons either congenital or acquired. Such are nasi or mother’s marks, scars, and disunited or badly united fractures, known to have existed upon the missing person (see Identification). In the case of the living, identification is more often a matter for the police officer than for the medical man. Bertillon and Galton have devised methods for the identification of criminals (see Anthropometry, and Finger-prints).

4. Marriage.—Under this head the medical jurist has to deal principally with the nubile age, viewed in the light of nature and according to legislative enactments, and with such physical circumstances as affect the legality of marriages, or justify divorce.

In Great Britain the age at which the sexes are first capable of propagating the species is later than in more southern climates. Ordeal does not occur before fifteen years of age for the male and fourteen for the female; exceptionally it occurs at the ages of thirteen and of twelve (or even less) respectively in the male and female. By law, nevertheless, parents and guardians may, in England, at any age below that of legal majority, take or register a child for marriage, and the only physical circumstances which in Great Britain form a bar to marriage are physical inability to consummate, and the insanity of one of the parties at the time of marriage. Both these circumstances have been pleaded and sustained in the law courts. In other countries minor physical circumstances, as disease, are held to invalidate marriage.

5. Impotence and Sterility.—These are of importance in connection with legitimacy, divorce and criminal assaults. Impotence may arise from disease or from accidents, and may be curable or incurable. Impotence (q.v.) is taken cognisance of by the law courts as a ground of divorce, and might, of course, he urged as a defence in a case of rape. Sterility is not a ground of divorce, but might be a question of importance in cases of legitimacy.

6. Pregnancy.—This subject presents one of the widest fields for medico-legal evidence. The limits of age between which pregnancy is possible are usually fixed by the appearance and cessation of the monthly flow; and these ordinarily begin about fourteen and cease at forty-five years of age. Exceptionally they appear as early as the tenth year, and may not cease till the end of the fifth decade of life. Cases, however, of a legal age, have occurred where a woman has conceived before menstruating; and a few doubtful cases of conception are recorded in women upwards of fifty or even sixty years of age. The general fact of pregnancy not occurring in the case is, however, taken as the foundation of the monthly flow—or fifty-three or forty-four years as the extreme limit of age—must be accepted as the safest guide in practice.

The limits of utero-estation are in England fixed by legislation. The French code fixes the term at five hundred days. The ordinary period is forty weeks and a half, or two hundred and eighty-three days from the cessation of the last monthly flow, e.g., the second case, where as far as is known, the period is neither exceeded, nor never exceeded, if ever reached. The uncertainty of females in fixing the exact date of conception has given rise to the discrepant opinions of physiologists on the subject. It is well known, however, that among the higher animals the period is precise; and impregnation and conception need not necessarily be coincident.

The signs of pregnancy are of the utmost importance to the medical jurist. He may be called upon to pronounce upon the virtue of a female, to sustain or rebut a plea for divorce, to determine whether a capital sentence shall be carried out, or to determine if it is probable that an heir will be born to an estate. Medical jurists classify the signs of pregnancy as uncertain or certain; it is the former which are most regarded by the public, but the latter are alone of probable value to the jurist. The usual and uncertain signs are the cessation of the monthly flow, nausea, sickness, a darkening of the areola and the formation of a secondary areola around the nipple, enlargement of the breasts, increased size of the abdomen, formation of a tumour in the womb, quickening, and the motions of the foetus. Also uncertain are the uterine swellings, which is a peculiar soft sound heard over the abdomen and synchronous with the maternal pulse and ballottement or the examination for the occurrence of a tumour in the abdomen, and the presence of months of pregnancy. The certain signs of pregnancy are the foetal limbs palpated through the abdomen by the physician, the pulsations of the foetal heart heard by means of the stethoscope, the pulsations being much quicker and not synchronous with the maternal pulse. This latter is inapplicable before the fourth month of gestation.

7. Parturition.—The imminence of the process of parturition is of comparatively little interest to the medical jurist; but the signs of recent delivery are all-important. These signs are the bruised, swollen, and lacerated state of the external genitals, relaxation and dilatation of the vagina and womb, the existence of a peculiar vaginal discharge known as the lochia, a relaxed and fissured condition of the abdominal walls, a peculiar aspect of the countenance, and the distended state of the breasts due to the secretion of milk. The lochial discharge is the most characteristic sign. All the signs may disappear within ten days of delivery, though this is not usual.

8. Monstrous and Hermaphrodites.—To destroy any living human being, however unlike a human creature it may be, is to commit a crime. Blackstone states that a monster which hath not the shape of mankind hath no inheritable blood; but the law hath not defined a monster, nor what constitutes a human form. The same author states that if, in spite of deformity, the product of birth has human shape, it may be an heir. Hermaphrodites are beings with malformations of the sexual organs, simulating a double sex. Physiologists do not admit, however, the existence of true hermaphrodites with double perfect organs, capable of performing the functions of both sexes.
9. Paternity and Affiliation.—These are often matters of great doubt. A considerable time may elapse between the absence or death of a father and the birth of his reputed child. As has already been said, three hundred days is the utmost limit to which physiologists would extend the period of uterine gestation. This subject involves questions respecting children born during a second marriage of the mother, posthumous children, bastardy, and alleged cases of posthumous children.

10. Presumption of Survivorship.—When two or more persons perish by a common accident, when a mother and her new-born child are found dead, and in a few analogous cases, important civil rights may depend upon the question which lived the longest; and much has been displayed in elucidating the disputes which have arisen in the law courts in such cases.

11. Maladies exempting from Discharge of Public Duties frequently demand the attention of the medical man. He may be called upon to decide whether a man is able to undertake military or naval service, to act as a jurymen without serious risk to life or health, or to attend as a witness at a trial.

12. Feigned and Simulated Diseases often require much skill and caution in order to detect the imposture.

13. The Signs of Death.—The determination of the actual existence of death assumes a certain importance in tropical countries, where the necessity for speedy interment may involve a risk of burial alive. Such an accident cannot well occur where a medical man confirms the existence of death, and in the United Kingdom, where burial rarely takes place before the lapse of forty-eight hours, such changes usually occur in the body as to render any error practically impossible. Within a varying period, usually not more than twelve hours, the body becomes rigid, owing to the development of rigor mortis or post mortem rigidity. The blood, which during life is equally distributed throughout the body, gravitates to the most dependent parts and develops a discoloration of the skin which is known as post mortem lividity or post mortem staining. At a variable period of time, dependent on the cause of death, also the temperature and moisture of the air to which the body is exposed, decomposition or putrefaction sets in. These changes after death are of great importance, not only as affording certain proof of death, but also because they furnish valuable information as to the probable time at which it occurred, and from the fact that they may alter or destroy evidence as to the cause of death.

14. Insanity or Mental Alienation.—A medical man may be required to give evidence in any of the law courts, civil, criminal or ecclesiastical, before commissions de lunatico inquirendo, or before a magistrate, as to the sanity or insanity of an individual; and he may have to sign certificates of unsoundness of mind with the view of providing for the safe custody and proper treatment of a lunatic. Hence he must be familiar with the chief forms of insanity (see Insanity), and be able to distinguish and treat each of these. He will also be required to detect feigned insanity, and to examine persons charged with crime with the view of preventing real lunatics from being treated as criminals.

II.—INJURIES TO THE PERSON

1. Deformation.—The signs of deformation are obscure and uncertain; and it is rather by the coexistence of several of the usual marks than the existence of any one sign, that any just conclusion can be arrived at.

2. Rape.—This crime consists in the carnal knowledge of a woman forcibly and against her will. The proofs of rape apart from the consistency of the woman's story, mainly depend on the presence of marks of violence, stains, &c. In all charges of rape, the woman and her assailant should be examined as soon as possible by a medical man, but such examination, it is important to remember, can only be carried out with the free consent of the party to be examined. It is to be noted that according to English law the slightest degree of penetration is sufficient to constitute the crime of rape.

3. Mutilation.—This may consist in the cutting or maiming of any member; castration is the most important, and perhaps but rarely effected as a crime. Self-mutilation, giving rise to false accusations, is occasionally resorted to.

4. Criminal Abortion.—This crime consists in unlawfully procuring the expulsion of the contents of the gravid uterus at any period short of full term. It must be noted that while this definition may be held to recognize the induction of premature labour by medical men in certain circumstances, yet, when the operation is necessary, a medical man should always protect himself from possible misconstruction of his action (i.e. criminal intent) by having a consultation with another practitioner. The means employed in criminal abortion to procure the desired result may be classed under three heads: (1) general violence to the birth, (2) abortion in some other manner, and (3) instrumental interference with the contents of the uterus. Among the drugs frequently employed for the purpose, although by no means always successfully, are ergot, strong purgatives, iron, rue, pennroyal, savin.

5. Homicide.—The legal sense of the term homicide excludes such injuries as are the result of either accident or of suicide. It embraces murder or willful homicide, manslaughter or culpable homicide, casual homicide, and justifiable homicide.

Ordinary homicide may be accomplished by several modes that sometimes are ascertained by examination of the body, e.g. poison.

As a preliminary in all cases of homicide, it is the duty of the medical jurist in the first place to ascertain the fact of death, and to distinguish between real and apparent death; and then to determine, if possible, the period at which death took place.

Infanticide, or child murder, is by the British law treated with the same severity as the murder of an adult. Indeed infanticide as a crime distinct from murder has no legal recognition. Practically this severity defeats itself, and hence an alternative charge of concealment of birth in England, or concealment of pregnancy in Scotland, is possible.

The iniquity of the old law which threw the onus of proof of still-birth on the mother now no longer exists, and the law demands strict proof of live-birth at the hands of the prosecution. Hence the subject involves nice points of forensic medicine. The child must be proved to have arrived at the period when there was a probability of its living (proof of viability); and as the establishment of respiration is necessary to prove live-birth the evidences of this act must be carefully investigated. The size and position of the lungs, and the state of the vessels concerned in foetal circulation, must be carefully noted. The foetal lungs are dark, dense and liver-like in appearance and consistence, and sink when immersed in water, whilst the fully matured lungs are tough, elastic, and float and crepitant when handled. Minor degrees of respiration are recognized by the appearance of little groups of dilated air-vesicles, and by the fact that, although the lungs have been removed, the surface of the lungs sinks in water when immersed, and the previously buoyant portion of lung then sinks in water. It is impossible, however, to distinguish certainly between a lung naturally inflated and one artificially insufflated.

It must be borne in mind that, although live-birth cannot be affirmed in the absence of signs of respiration, the presence of these signs is not proof of live-birth in the legal sense of the term. The demand for breath and breathing is the place whilst the child is still either wholly or partially within the maternal passages, and in some special cases whilst still within the uterus itself.

The proofs of respiration may be to such an extent as to leave no doubt as to live-birth—have been found, the cause of death is then to be investigated. Wounds, and other forms of injury, must be sought for. There may be signs of strangulation or asphyxiation, or an impression of the face or neck on the brain, the administration of a poison, or other means of procuring death. It must be borne in mind that some of these causes may be brought about by omission, or even by an act innocent, but natural. Thus unrelieved pressure of the navel-string on the neck of the child; suffocation from immersion of the face of the child in the maternal discharges, or by pressure of clothes on the mouth. Death may result from hemorrhage through neglect to tie the navel-string, or the infant may perish from exposure to cold.

In the case of exposed infants it is important to ascertain the real mother. As such exposure usually takes place soon after birth, and as the delivery in the suspected mother is the best method of proving the relation.
Death from Asphyxia.—Among the forms of violent death due to this cause are drowning, hanging, strangulation, gassing, asphyxiation, suicide, and accidental death. The cause of death is usually a gradual diminution of the blood through the brain acting as a poison upon that organ; and this is attended with all the phenomena of asphyxia, as in suffocation. The term asphyxia is applied to those phenomena in which the supply of oxygen in the arterial blood, through exclusion of air, sinks below the normal, the respiratory movements grow deeper and at the same time more frequent; both the inspiratory and expiratory phases of the respiration take place; then these movements become less frequent; the rhythm becomes irregular, so that each breath becomes a more act or less pronounced, which has been term the convulsive stretching of the whole body; and with extended limbs and a straightened trunk, with the head thrown back, the mouth widely open, the face drawn and the nostrils dilated, the last breath is taken. The above phenomena are not all observed except in cases of sudden and entire exclusion of air from the lungs. In slow asphyxia, where the supply of air is gradually diminished (e.g. in drowning), the phenomena are much the same, but with minor differences. The appearances of the body differ in drowning and asphyxia are various. There may be pallor of the countenance, or this may be livid and swollen. The air passages are filled with frothy mucus, and there may even be a simple exanguination. The last breath is taken. The phenomena of death are more prolonged. There may be no mark of the cord visible. The mark, when present, usually follows an oblique course, and is high up the neck. The gas of death is not always present. When the body is placed in the water, the breath may be done slowly whilst the body is still warm there may be a post-mortem mark distinguishable from the mark observed in death from drowning, but must be forgotten.

Strangulation may occur from the impaction of any substance in the glottis, or by covering up the mouth and nose. It is frequently of accidental origin, as when substances become accidentally impacted in the throat, and when infants are overlaid. The phenomena are those of pure asphyxia, which have already been described. Of post-mortem examination the surface of the lungs is found covered with minute extravasations of blood, known as punctated ecchymosis. Strangulation may be accomplished by drawing a cord tightly round the neck, or by forcibly compressing the windpipe (throttling). Hence there may be either a circular mark round the neck, not so oblique as after hanging, or the marks of the fingers may be found about the region of the larynx. These are more or less numerous, and the larynx and windpipe may be broken. The mark of the ligature is often low down in the neck. The signs of asphyxia are present in a case of drowning.

Mephitism.—In the United Kingdom this last form of death usually results accidentally from an escape of lighting gas, the danger having been much increased in many towns owing to the addition of carbureted waggons to the ordinary supply. The carbureted gas is contained in ordinary lighting gas to the extent of about 6 to 8%, and is extremely fatal when inhaled. Carbureted water-gas contains about 28%, and when mixed with ordinary lighting gas the percentage of carbonic oxide is thus very much increased. As a mode of assassination it is seldom employed, but is frequently resorted to on the continent of Europe by suicides, charcoal furnes being commonly used for the purpose.

6. Death from Starvation.—Cases occur in which it is important to distinguish this from other modes of death. In such cases the skin becomes harsh and dry, and may acquire a peculiar odour; the subcutaneous fat disappears; the gums shrink away from the teeth; the tongue and mouth become dark-coloured and dry; the eyes are bloodshot; the intestines become thin and their coats translucent; the gall-bladder is distended. The period of total abstinence from food required to kill an adult is unknown, and greatly depends upon whether there be access to liquid. In some cases persons have been able to subsist on little or no nourishment for long periods, the body being in a state of quasi-suffocation.

7. Death from Extremes of Temperature.—(1) Death from cold is not often observed in the British Isles. A portion only of the body, as the extremity of a limb, may perish from extreme cold. After the first sensation of tingling experienced on exposure to severe cold, loss of sensation supervenes, with languor and an irresistible propensity to sleep. The tendency to this extreme danger in such cases. (2) Death from extreme heat usually occurs in the form of burning and scalding, attended with destruction of a large portion of the cutaneous structures. Here the cause of death is obvious. The human body is capable of withstanding a temperature of 119° Fahrenheit for a considerable period with impunity. Sunstroke, or a cerebral affection brought on by too great exposure to a hot atmosphere, especially whilst undergoing fatigue.

8. Death by Lightning.—Lightning or an electric current may cause instant death. No visible marks of the effects of the electric current may be left, or the body may be singed or discoloured, or the skin may be perforated at one or two spots.

9. Injuries or Wounds.—Theseinclude in a medico-legal sense not only those characterized as incised, punctured, contused, or fractured wounds, but also the injuries produced by firearms, fractures, dislocations, &c. One of the chief questions which have to be decided in all forms of violent death is whether it was the result of accident, suicide or murder. In cases of fatal wounding, among the points to be noted, which will help to decide the question, are the situation, direction and extent of the wound, the position in which the body and any weapon may be found, together with the presence and distribution of any blood marks and the signs of a struggle. In wounds caused by firearms the injury, if suicidal, is usually situated in a vital and accessible part of the body, the temple, mouth, and chest being the favourite situations; if injurious, the character of the discharge from the weapon close to the body, viz. besides the wound of entrance of the bullet, there are singeing of the cuticle and hair, and blackening of the area immediately surrounding the wound, from particles of un consumed powder being driven into the skin and from the smoke of the discharge. These effects are naturally not produced when the weapon is discharged at a distance exceeding 2 or 3 ft., as usually happens in cases of homicidal shooting. They may also be wanting in undoubted suicidal wounds produced by revolvers and cartridges filled with amonite or other smokeless powders. Death from burning is generally accidental, very rarely suicidal, and when homicidal is usually employed to conceal traces of other violence inflicted upon the body. In large conflagrations death is not always due to burning. Charred bodies may be found presenting various injuries due to the fall of beams, crushing, the trampling of others trying to escape, &c., or fractures and lacerations may be due simply to the actions of the heat. Death may result from such injuries, or from suffocation by the smoke or combustion, before the victim is affected by the actual fire. Spontaneous combustion of the body has been stated to occur, but the evidence upon which the cases rest is not well authenticated.

Punctured wounds or stab require minute attention; for there have been instances in which death has been produced by an instrument so small as a pin thrust into a vital part. Wounds of the head are always dangerous, especially if the blow has been severe. The person so wounded may die without division of the skin, or fracture
of the bones, as happens in what is known as concussion of the brain. Contusions which do not divide the skin may fracture the skull; or the inner table of the skull may be fractured without the outer being broken or depressed. Even wounds of the scalp may prove fatal, as the scalp extends under the outer table of the skull. Wounds of the head are more dangerous than cuts, as more likely to excite fatal inflammation. When the brain and its membranes are injured, all such wounds are generally fatal. Wounds of the face and neck are often dangerous, always disfiguring, and productive of serious inconvenience. Wounds of the neck are always serious whenever more than the skin is divided. The danger of opening large blood-vessels, or wounding important nerves, is enormous. Even wounds of the neck which do not prove immediately fatal, from the entrance of air into the vessel, and its speedy conveyance to the heart. A blow on the neck has instantly produced a shock similar to an immediate death of the nerve. A shock of pneumatic or the sympathetic. Dislocations and fractures of the bones of the neck prove instantly fatal. Wounds of the chest are always serious when the cavity is penetrated, though persons may recover from wounds of the lungs, which take many days for some time considerable wounds of the heart. This last is an important fact; because we are not always to consider the spot where the body of a person killed by a wound of the heart, and apparently remaining where he fell, is found as that in which the fatal wound was inflicted. Instances have occurred of persons surviving severe wounds of the heart for several days. Broken ribs are never without danger, and may be serious. Contusions may arise from the chance of inflammation extending forwards. Wounds penetrating both sides of the chest are generally considered as fatal; but possibly there may be recovery from such. Wounds of the abdomen are even more complete. The abdomen is filled with blood and injuring the peritoneum are highly perilous, from the risk of severe inflammation. Wounds of the stomach or intestines, or of the gall-bladder, generally prove mortal, from the effusion of their contents into the peritoneal cavity producing fatal inflammation. Wounds of the liver, spleen or kidneys are generally soon mortal, from the great vascularity of those organs. Wounds of the extremities, when fatal, are generally produced by some injury to one of the larger bones, from the consequences of inflammation and gangrene, or from the shock to the system when large portions of the limb are forcibly removed, as in accidents from machinery, and in wounds from firearms.

Blood Stains.—The examination of blood stains is a frequent and important operation in criminal charges. Blood stains when fresh and abundant can be recognized without difficulty, but when old, or after being acted upon by certain substances, their identity is not readily determined. The tests which may be applied to a suspected stain consist of: (1) that of nature; (2) that of concordance, which is some solution of a sugar which will soften and cause separation of the dried blood corpuscles without altering their characteristic appearance. Such fluids are solutions of glycine and water of a specific gravity of 1.010, 4% of alkali, and 1,000 parts of sugar. (3) The test for the presence of bile which affords evidence of the nature of the stain. (2) Chemical tests. (a) Heat applied to a solution obtained by soaking some of the stained fabric in hot water, causes the place to be discolored. A blood solution will turn red, and blots its red colour on application of heat, while at the same time a buff-colored precipitate is formed. (b) On applying a drop of freshly prepared tincture of guaiacum and then some ozone ether or peroxide of hydrogen to the stain, a blue colour is obtained if blood be present. Many other substances, however, give the same reaction. (c) If, even to the smallest particle of dried blood, a fragment of common salt and some glacial acetic acid be added, and the latter is then heated, the blood is dissolved. A similar effect results when a powdered rhomboid crystals—haematin crystals—will be found to have formed, and they can be recognized under the microscope. (3) Spectroscopic test. (a) The addition of iodine from a stain shows a spectrum having two dark bands from Fraunhofer’s lines D and E (oxyhaemoglobin). On adding ammonium sulphide to the solution the haemoglobin is reduced and only one broad dark band is seen (redetermination). (b) On adding a small quantity of potash of blood, alkaline haematin is formed, and this again is transformed on the further addition of ammonium sulphide into reduced haematin of haemochromogen, which gives a very characteristic spectrum of the lines B and C. (d) The addition of potash of blood, which bears with soap to fix or render blood stains insoluble. Vegetable dyes may likewise give red solutions, but they may be distinguished from blood by the addition of ammonium, which alters the colour of the former, but rather intensifies the red colour of a blood stain. The differentiation between human blood stains and those produced by the blood of other animals, more especially domestic animals, is a matter of great importance to the medical jurisprudence. When the blood stain is fresh, measurement of the corpuscles may decide the question, but in the case of dry and old stains it is impossible. Wounds which penetrate the brain are often dangerous, always disfiguring, and productive of serious inconvenience.

MEDICAL JURISPRUDENCE

10. Poisoning.—There is no exact definition of a poison (q.v.). Popularly, substances which destroy or endanger life when swallowed in small quantity are called poisons, but a scientific definition would also include many substances which are injurious to health in large doses or only after repeated administration, and which act not only when swallowed, but also when taken into the system through other channels, e.g. the skin or the lungs. The term poison is often used where it relates to poisons, their nature, methods of detection, the symptoms produced, but the general treatment of poisoning, is called Toxicology, and is one of the most important subjects included under the term Medical Jurisprudence.

The medical evidence in cases of poisoning rests upon—(1) the symptoms produced during life; (2) the post mortem appearances; (3) the chemical analysis and detection of the substance in the body, or in the excretions and vomited matters, or in articles of food; (4) experiments on animals in the case of certain poisons where other conclusive evidence is difficult to obtain. The treatment of cases of poisoning will vary according to the substance taken, but the general principles which should be followed are: (a) to get rid of the poison by means of the stomach-pump, or by washing out the stomach with water through a soft rubber tube, or by giving an emetic such as mustard, sulphate of zinc, ipecacuanha; (b) to neutralize the poison by giving a substance which will form with it an innocuous compound (e.g. in the case of the strong acids by administering magnesia or common whiting), or which has an opposite physiological action (e.g. atropine in opium poisoning). (c) to promote the elimination from the body of the poison by which it is absorbed. (d) general treatment of any dangerous symptoms which appear, as by stimulation in collapse or artificial respiration in asphyxia.

Food Poisoning (see also Adulteration).—Foods may prove noxious from a variety of causes: (1) The presence of metallic poisons, as in peas artificially coloured with copper salts, in tinned foods from dissolved tin salts, &c. (2) The contamination of any food with the specific germs of disease, for example, milk infected with the germ of enteric fever. (3) The presence in meat of parasites, such as the Trichina spiralis, or of disease in animals, capable of transmission to man, such as tuberculosis, or the presence of poison in the flesh of animals which have fed on substances harmless to them but poisonous to human beings. Grain may be infected with parasitic fungi of a poisonous character, as for example Claviceps purpurea, causing epidemics of ergotism. (4) Foods of various kinds may contain saprophytic bacteria which elaborate certain poisons, either before or after the food is taken. It is chiefly in relation to food-poisoning from the last-mentioned cause that our knowledge has been increased in recent years.

Many cases of food-poisoning, previously of mysterious origin, can now be explained by the action of bacteria and the products which they give rise to—tox-albumins, toxins, toxis—by splitting up proteid substances. It is not necessary that the food should show evident signs of putrefaction. It may not do so, yet the disease may have been caused by the ingestion of a toxic substance. In such cases a chemical poison, developed by putrefactive bacteria before the food was eaten, quickly acts upon the system.
At the close of the 16th century Ambrose Paré wrote on monsters, on simulated diseases, and on the art of drawing up medico-legal reports; Plineus also published his treatise on virginity and defloration. About the same time as these stimuli to the study of forensic medicine were being made known in Paris, the first systematic treatise on the science appeared in Sicily in the form of a treatise De relationibus medicorum by Fidele. Paolo Zacchia, the illustrious Roman medical jurist, moreover, published from 1621 to 1635 a work entitled Quaestiones medico-legales, which marks a new era in the history of the science—a work which displays an immense amount of learning and sagacity in an age when chemistry was in its infancy, and physiology very imperfectly understood. The discovery of the circulation of the blood by Harvey soon followed, and gave a new impetus to the study of those branches of forensic medicine having direct relations to physiology; and to Harvey we owe the idea how to apply Galen's observations on the differences between the foetal and the adult lungs to the elucidation of cases of supposed infanticide. About this time, too, Sebiz published two treatises, on the signs of virginity and on the examination of wounds respectively. In the former he contended that the hymen was the real mark of virginity; but this was denied by Augenio and Gassendi. In 1663 Thomas Bartholin investigated the period of human uterine gestation, a subject which had engaged the attention of the whole generation of midwives. He also promulgated the "hydrostatic test" for the determination of live-birth—a test still in use, and applied by observing whether the lungs of an infant float or sink in water. J. Swammerdam explained the rationale of the process in 1677; but it was not till 1682 that it was first practically applied by Jan Schreyer.

Germany, ever the leader in questions of forensic medicine, introduced the first public lectures on medical jurisprudence. Michaelis gave the first course about the middle of the 17th century in the university of Leipzig; and these were followed by numerous others. The early authors in medicine or forensic medicine were generally also midwives, and from such as diversorum aquis, in quo quis virum mortuam aequis submersus, strangulatus, aut vulneratum fuerit, et De officinis medicis duplicis, clinici et forensis. Welsh and Amman wrote on the fatality of wounds, and Licetus on monsters.

From the time of Ambrose Paré the mode of conducting investigations in forensic medicine had attracted in France; and in 1603 Henry IV. authorized his physician to appoint persons skilled in medicine and surgery to make medico-legal examinations and report in all cases of homicide. The law of 1632, difficulties having arisen, Louis XIV. created hereditary royal physicians and surgeons for the performance of like duties. These, having become a corrupt and venal body, were suppressed in 1790. The only works on forensic medicine which appeared in France during the 17th century, however, were Gendry's Sur les moyens de bien rapporter à justice et Blégny's Doctrine des rapports en chirurgie. At the beginning of the 18th century the latter was superseded as a text-book by Devaux's L'Art de faire des rapports en chirurgie. Valenti followed with two works, which were finally incorporated in his Corpus juris medicó-legale, which appeared in 1722. This work is a vast storehouse of medico-legal information, and a summary of the knowledge of the time.

Professorships for teaching the subject were founded in the German universities early in the 18th century, and numerous treatises on forensic medicine were published. Telchmeyer's Institutiones medicinae legalis long formed the text-book of the subject; and Alberti, professor of legal medicine at Halé, in his Systema gave to the world a most complete and laborious treatise on the science. His industrious collection of facts renders his works a precious mine of information. Indeed towards the close of the 18th century the Germans were almost the only cultivators of legal medicine. But in France the celebrated case of Ville-blanche attracted attention to the subject, and called forth Louis, who in a memoir on utero-gestation attacked with powerful arguments the pretended instances of protracted pregnancy, and paved the way for the adoption in the Code Napoléon of
three hundred days as the limit of utero-gestation, a period in precise accordance with the ancient Roman law of the Twelve Tables. Louis also wrote on death from hanging, and pointed out the mode by which we may distinguish murder from suicide under such circumstances. It is he who is credited with having been the first in France to publicly teach the just application of medical knowledge to jurisprudence. Fodéré’s celebrated Traité de médecine légale appeared in 1798, and marks a new era in the annals of legal medicine.

No British 1811-1817; H. H. L. Bailey wrote systematically on forensic medicine till 1831; Dr Samuel Farr published a short treatise on the Elements of Medical Jurisprudence; but this was merely an abridgment of an earlier work of Fazellus. Previous writers—as Mead, Munro, Denman, Percival and the two Hunters—had, however, dealt with fragments of the subject; nevertheless the science as a whole was little appreciated or recognized in this country during the 18th century.

In the 19th century France took the lead; and the institution of three professorships of forensic medicine at the beginning of the 19th century. Its progress has since been by no means slow or unimportant; and the subject now forms a recognized and obligatory portion of medical study. The first lectures delivered in Great Britain were given in the Forensic Faculty of the University of Edinburgh in 1801; the first professorship was held by his son in 1803. Dr Alfred Swaine Taylor gave the first course of lectures delivered in England, at Guy’s Hospital in 1831; and in 1863 the university of London made forensic medicine a separate subject for examination and honours for medical graduates. In 1852 there was not in the English language any treatise of authority either on medical jurisprudence or on any important division of the subject; for it was not till the following year that the useful compendium of Paris andFombert was published; and even in the middle of the 19th century medical jurisprudence may be said to have been almost in its infancy, as compared with what it is now. From 1826 Britain produced an abundant crop of literature on forensic medicine. Sir Robert Christison’s admirable treatise on Toxicology, Dr A. S. Taylor’s Principles and Practice of Medical Jurisprudence (1890 edition), F. W. Balfour’s Elements of Medical Jurisprudence, Dr Guy’s Forensic Medicine, and Ogston’s Lectures on Medical Jurisprudence have become well-known and widely circulated works. The separate memoirs of Taylor, Christison, Guy and others are also storehouses of facts and deductions in the science. America, too, has not been behindhand in the race. F. Wharton and M. Stillé’s Manual, Wormley’s Toxicology, and the works of Beck and Reese have furthered the study of the science.

Intoxication (London, 1898); Vaughan, Criminal Pharmacology, vol. iii, article “Pomotaxins, Toxins and Leucomane” (London, 1898); Marschak, Handbuch der gerichtlichen Medicin (Thieme, Leipzig); Hofemann, Lehrbuch der gerichtlichen Medicin (Wien, 1898); Strassmann, Lehrbuch der gerichtlichen Medicin (Stuttgart, 1899); Kunkel, Handbuch der Toxicologie (Jena, 1899); Brousardel, L’Infanticide, La Pendance, &c., (Paris, 1898).
and art. But his father had mainly trained him to commerce, for which he had a special liking and aptitude. He was devoted to business to the day of his death, and like his forefathers derived pecuniary advantage from his friendly relations with the papal court. He accompanied Pope John XXIII. to the Council of Constance, transacted a vast amount of business in that city, and made very large gains. He then travelled in Germany, and after his return to Florence discharged several ambassadorial missions. At the death of his father he was possessed of a vast fortune and an extended experience, and inherited the leadership of the opposition to the then dominant party of the greater gilds headed by Rinaldo degli Alibizzi, Palla Strozzi and Niccołò da Uzzano. Of gentle and kindly manners, generous in lending and even in giving money whenever he could gain popularity by that means, at critical moments he frequently came to the succour of the government itself. He was very dexterous in turning his private liberalties to account for the increase of his political prestige, and showed no less acumen and still fewer scruples in making use of his political prestige for purposes of pecuniary profit. Indeed, whenever his own interests were at stake, he showed himself capable of positive villainy, although this was always tempered by calculation. Cosimo proved his skill in these knavish arts during the course of his government in Lucca. He had joined the Alibizzi in urging on this war, and many writers assert that he turned it to much pecuniary advantage by means of loans to the government and other banking operations. When, however, military affairs went badly, Cosimo joined the discontented populace in invectives against the war and those who had conducted it. This won him an enormous increase of popularity, but the hatred of the Alibizzi and their friends augmented in equal degree, and a conflict became inevitable. The Alibizzi, who were far more impetuous and impatient than Cosimo, were now bent upon revenge. In 1432 one of their friends, Bernardo Guadagni, was elected gonfalonier, and thereafter Cosimo dei Medici was called to the palace and summarily imprisoned in the tower. A general assembly of the people was convoked and a balta chosen, which changed the government and sent Cosimo into exile. Undoubtedly the Alibizzi party would have preferred a heavier sentence, but they did not dare to attempt their enemy’s life, being well aware of the great number of his adherents. Cosimo had some apprehension that he might be imprisoned in prison, but Federigo dei Malavolti, captain of the palace guard, showed him the utmost kindness, and, to soothe his fears, voluntarily shared his meals. On the 3rd of October the prisoner was sent to Padua, his allotted place of exile.

The Alibizzi speedily saw that they had done rather too much or too little. While seeking to keep the government entirely in their own hands, they beheld the continual growth of the Medici party. When it was necessary to make a campaign in Romagna against the mercenary captains commanding the forces of the duke of Milan, it was plainly seen that in banishing Cosimo the republic had lost the only citizen banker in a position to assist it with considerable loans. The Florentines were defeated by Ficocino in 1434, and this event greatly increased the public exasperation against the Alibizzi. Meanwhile Cosimo, who had gone to Padua as a private individual, was entertained there like a prince. Then, being permitted to transfer his residence to Venice, he entered on a course of lavish expenditure. He was overwhelmed with letters and appeals from Florence. Finally, on the 1st of September 1434, a signory was elected composed of his friends, and his recall was decreed. Rinaldo degli Alibizzi determined to oppose him by the instigation of Piazza with a band of armed men; but his attempt failed, and he left the country to return no more. The Medici were now reinstated in all their former dignities and honours, and Cosimo, on the evening of the 6th of September, rode past the deserted mansions of the Alibizzi and re-entered his own dwelling after an exile of a year. For three centuries, dating from that moment, the whole history of Florence was connected with that of the house of Medici.

Cosimo's first thought was to secure himself against all future risk of removal from Florence, and accordingly he drove the most powerful citizens into exile to all parts of Italy. Nor did he spare even his former political adversary, Palla Strozzi, although the latter had been favourable to him during the recent changes. His rigour in this particular case was universally censured, but Cosimo would tolerate no rivals in the city, and was resolved to abase the great families and establish his power by the support of the lower classes. He was accustomed to say that states could not be ruled by paternosters. Still, when cruelty seemed requisite, he always contrived that the chief odium of it should fall upon others. When Nerì Capponi, the valiant senator and able diplomatist, gained great favour, and was conspicuous in public process, and his influence was further increased by the friendship of Baldaccio d’Anghiari, captain of the infantry, Cosimo resolved to weaken his position by indirect means. Accordingly, when in 1441 a partisan of the Medici was elected gonfalonier, Baldaccio was instantly summoned to the palace, imprisoned, murdered, and his body hurled from the window. No one could actually fix this crime upon Cosimo, but the majority believed that he had thus contrived to rid himself of one enemy and cripple another without showing his hand. It was impossible for Cosimo to acquire the power of the Medici but by some means, and he therefore resolved to make it worth his while to become gonfalonier, since the term of office only lasted two months. It was necessary to discover some other way without resorting to violence; he accordingly employed what were then designated “civil methods.” He managed to attain his object by means of the balta. These magistracies, which were generally renewed every five years, placed in the ballot-bags the names of the candidates from whom the signory and other chief magistrates were to be chosen. As soon as a balta favourable to Cosimo was formed, he was assured for five years of having the government in the hands of men devoted to his interests. He had comprehended that the art of politics depended rather upon individuals than institutions, and that he who ruled men could also dictate laws. His foreign policy was no less astute. His great wealth enabled him to supply money not only to private individuals, but even to foreign potentates. Philippe de Comines tells us that Cosimo frequently furnished Edward IV. of England with sums amounting to many hundred thousand florins. When Tommaso Parentucci was still a cardinal, and in needy circumstances, Cosimo made him considerate loans without demanding guarantees of payment. On the cardinal’s accession to the papacy he wasNicholas V, but he was very well disposed towards Cosimo, and employed the Medici bank in Rome in all the affairs of the curia. At the time when Francesco Sforza was striving for the lordship of Milan, Cosimo foresaw his approaching triumph, showed him great friendship, and aided him with large sums of money. Accordingly, when Sforza became lord of Milan, Cosimo’s power was doubled. Without the title of prince, this merchant showed royal generosity in his expenditure for the promotion of letters and the fine arts. Besides his palace in the city, he constructed noble villas at Careggi, Fiesole and other places. He built the basilica of Fiesole, and that of St Lorenzo in Florence, and enlarged the church and monastery of St Mark. Even in distant Jerusalem he endowed a hospice for the use of pilgrims. The artists of the day comprised men like Donatello, Brunelleschi, Ghiberti, Luca della Robbia, and many others, and Cosimo’s magnificient commissions not only developed their powers but stimulated other men of wealth to the patronage of art. Without being a scholar, Cosimo was a genuine taste for letters. He purchased many Greek and Latin manuscripts of this sort, and translated them at St Mark’s at his own expense, and founded another in the abbey of Fiesole. The Greek refugees from Constantinople found a constant welcome in his palace. During the Council of Florence (1439–1442), Gemistus Pletho spoke to him with enthusiasm of the Platonic philosophy. Cosimo was so deeply attracted by the theme that he decided to have the young Marsilio Ficino trained in philosophy and Greek learning in order to make a Latin translation of the complete works of Plato. And thus a
Piero the Gouty.

From fact to fancy.

Florence and her literary means, mainly the Ficino, was easily disposed of by the hands of Piero, surnamed the Gouty, Cosimo’s only surviving legitimate son. Afflicted by gout, and so terribly crippled that he was often only able to use his tongue, the new ruler soon discovered that a plot was on foot to overthrow his power. However, showing far more courage than he was supposed to possess, he had himself borne on a litter from his villa to Florence, defeated his enemies’ designs, and firmly re-established his authority. But his success may be mainly attributed to the enormous prestige bequeathed by Cosimo to his posterity. Piero died at the end of five years’ reign, on the 3rd of December 1469, leaving two sons, Lorenzo (1449-1492) and Giuliano (1453-1478). The younger, the gentler and less ambitious of the pair, was quickly removed from the world.

Lorenzo, on the contrary, at once seized the reins of state with a firm grasp, and was, chronologically, the second of the great men bestowed upon Italy by the house of Medici. In literary talent he was immensely superior to Cosimo, but greatly his inferior in the conduct of the commercial affairs of the house. In politics he had nobler conceptions and higher ambitions, but he was more easily carried away by his passions, less prudent in his revenge, and more disposed to tyranny. He had inherited from his father a looseness of life, and the earliest years of his reign were far more turbulent than the more peaceful ones of his father Giuliano. As a mild and yielding disposition, had only a nominal share in the government.

Lorenzo’s policy, although prosecuted with less caution, was still the old austere and fortunate policy initiated by Cosimo. But the grandson bestowed no care upon his commercial interests, although squandering his fortune with far greater lavishness. Accordingly he was sometimes driven to help himself from the public purse without ever being able to assist it as Cosimo had done. All this excited blame and enmity against him, while his greed in the matter of the alum mines of Volterra, and the subsequent sack of that unhappy city, were matters for which there was no excuse. Among his worst enemies were the Pazzi, and, as they formed a very powerful clan, he sought their ruin by competing with them even in business transactions. They were on the point of inheriting the large property of Giovanni Borromeo when Lorenzo hurriedly caused a law to be passed that altered the right of succession. The hatred of the Pazzi was then expended on him, and in addition to these things there ensued a desolate quarrel with Pope Sixtus IV., a man of very impetuous temper, who, on endeavouring to erect a statue on the frontiers of the Florentine republic for the benefit of his nephews, found a determined and successful opponent in Lorenzo. Consequently the Pazzi and Archbishop Salviati, another enemy of Lorenzo, aided by the nephews of the pontiff, who was himself acquainted with the whole matter, determined to put an end to the family. On the 26th of April 1478, while Giuliano and Lorenzo were attending high mass in the cathedral of Florence, the former was mortally stabbed by conspirators, but the latter was able to beat back his assailants and escape into the sacristy. His life was saved, and no longer having to share the government with a brother, he commenced the opportunity to wreak cruel vengeance upon his foes. Several of the Pazzi and their followers were hanged from the palace windows; others were hacked to pieces, dragged through the streets, and cast into the Arno, while a great many more were condemned to death or sent into exile. Lorenzo seemed willing and able to become a tyrant. But he stopped short of this point. He knew the temper of the city, and had also to look to fresh dangers threatening him from without. The pope had pronounced him, put Florence under an interdict, and, being succeeded by King Ferdinand of Aragon, was preparing to set forces against the republic. The Florentines began to tire of submitting to so many hardships in order to support the yoke of a fellow-citizen. Lorenzo’s hold over Florence seemed endangered. But he rose superior to the difficulties by which he was encompassed. He boldly journeyed to Naples, to the court of King Ferdinand of Aragon, who was reputed to be as treacherous as he was cruel, and succeeded in obtaining from him an honourable peace, that soon led to a reconciliation with Sixtus. Thus at last Lorenzo found himself completely master of Florence. But, as he had so lately been in the hands of the Pazzi, he was always requisite, in order to retain his supremacy, that he should renew the usual manœuvre at the close of that term and have another elected equally favourable to his aims. This was often a difficult achievement, and Lorenzo showed much dexterity in overcoming all obstacles. In 1480 he compassed the institution of a new council of seventy, which was practically a permanent balia with extended powers, inasmuch as it not only elected the chief magistrates, but had also the administration of numerous state affairs. This permanent council of devoted adherents once formed, its security was firmly established. By this he was enabled to control the affairs of the state were always conducted by intelligent and experienced men, who promoted the public prosperity. Florence was still called a republic; the old institutions were still preserved, if only in name. Lorenzo was absolute lord of all, and virtually a tyrant. His immorality was scandalous; he kept an army of spies; he frequently meddled in the citizens’ most private affairs, and exalted men of the lowest condition to important offices of the state. Yet, as Guicciardini remarks, “if Florence was to have a tyrant, she could never have found a better or more pleasant one.” In fact all lasted for only five years, and Lorenzo’s works made enormous progress. The civil equality of modern states, which was quite unknown to the middle ages, was more developed in Florence than in any other city of the world. Even the condition of the peasantry was far more prosperous than elsewhere. Lorenzo’s authority was not confined to Tuscany, but was also very great throughout the whole of Italy. He was on the friendlyest terms with Pope Innocent VIII., from whom he obtained the exaltation of his son Giovanni to the cardinalate at the age of fourteen. This boy-cardinal was afterwards Pope Leo X. From the moment of the decease of Sigismund IV., the union of Florence and Rome became the basis of Lorenzo’s foreign policy. By its means he was able to prevent the hatreds and jealousies of the Sforzas of Milan and the Aragonese of Naples from bursting into the open conflict that long threatened, and after his death actually caused, the beginning of new and irreparable calamities. Hence Lorenzo was styled the needle of the Italian compass.

But the events we have narrated cannot suffice for the full comprehension of this complex character, unless we add the record of his deeds as a patron of letters and his achievements as a writer. His palace was the school and resort of illustrious men. Within its walls were trained the two young Medici afterwards known to the world as Leo X. and Clement VII. Ficino, Poliziano, Pico della Mirandola and all members of the Platonic academy were its constant habitués. It was here that Pulci gave readings of his Morgante, and Michelangelo essayed the first strokes of his chisel. Lorenzo’s intellectual powers were of exceptional strength and versatility. He could speak with
equal fluency on painting, sculpture, music, philosophy and poetry. But his crowning superiority over every other Maecenas known to history lay in his active participation in the intellectual labours that he promoted. Indeed at certain moments he was positively the leading spirit among the litterati of his time. He was an elegant prose writer, and was likewise a poet of real originality. At that period Italians were forsaking erudition in order to forward the revival of the national literature by recurring to the primitive sources of the spoken tongue and popular verse. It is Lorenzo's lasting glory to have been the initiator of this movement. Without being—as some have maintained—a poet of genius, he was certainly a writer of much finish and eloquence, and one of the first to raise popular poetry to the dignity of art. In his Ambra, his Caccia del falcone and his Nencia da Barberino, he gives descriptions of nature and of the rural life that he loved, with the graphic power of an acute and tasteful observer, joined to an ease of style that occasionally sins by excess of homeliness. Both in his art and in his politics he learnt upon the people. The more oppressive his government, the more did he seek in his verses to incite the public to festivities and lull it to slumber by sensual enjoyments. In his Ballate, or songs for dancing, and more especially in his carnival songs, a kind of verse invented by himself, Lorenzo displayed all the best qualities and worst defects of his muse. Marvelously and spontaneously elegant, very truthful and fresh in style, fertile in fancy and rich in colour, they are often of a most revolting indecency. And these compositions of song, being a periodically station in the city were often sung by their author in the public streets, in the midst of the populace.

Lorenzo left three sons—Pietro (1471-1503), Giovanni (1475-1521) and Giuliano (1479-1516). He was succeeded by Pietro, whose rule lasted but for two years. During this brief term he performed no good deeds, and only displayed inordinate vanity and frivolity. His conduct greatly helped to foment the hatred between Lodovico Sforza and Ferdinand of Naples, which hastened the coming of the French under Charles VIII., and the renewal of foreign invasions. No sooner did the French approach the frontiers of Tuscany than Pietro, crazed with fear, hastened to meet them, and, basely yielding to every demand, accepted terms equally humiliating to himself and the state. But, returning to Florence, he found that the enraged citizens had already decreed his deposition, in order to reconstitute the republic, and was therefore compelled to escape to Venice. His various plots to reestablish himself in Florence were all unsuccessful. At last he went to the south of Italy with the French, was drowned at the passage of the Garigliano in 1503, and was buried in the cloister of Monte Cassino.

The ensuing period was adverse to the Medici, for a republic government was maintained in Florence from 1494 to 1512, and the city remained faithful to its alliance with the French, who were all-powerful in Italy. Cardinal Giovanni, the head of the family, resided in Rome, playing the part of a circle of literati, artists and friends, seeking to increase his popularity, and calmly waiting for better days. The battle of Ravenna wrought the downfall of the fortunes of France in Italy, and led to the rise of those troops which the French had sent to subdue the republic and reestablish the Medici. Pietro had now been dead for some time, leaving a young son, Lorenzo (1492-1519), who was afterwards duke of Urbino. The following year (1513) Cardinal Giovanni was elected pope, and assumed the name of Leo X. He accordingly removed to Rome, leaving his brother Giuliano with his nephew Lorenzo in Florence, and accompanied by his cousin Giulio, who was a natural son of the Giuliano murdered in the conspiracy of the Fazzi, and was soon destined to be a cardinal and ultimately a pope. Meanwhile his kinsmen in Florence continued to govern that city by means of a balia. And thus, being masters of the whole of central Italy, the Medici enjoyed great authority throughout the country and their ambition plunged itself for still higher flights. This was the moment when Niccolò Machiavelli, in his treatise The Prince, counselled them to accomplish the unity of Italy by arming the whole nation, and expelling its foreign invaders.

Leo X., who is only indirectly connected with the history of Florence, gave his name to the age in which he lived in consequence of his magnificent patronage of art and letters in Rome. But he was merely a clever marauder, and had no literary gifts of his father Lorenzo. He surrounded himself with versifiers and inferior writers, who embellished his board and accompanied him wherever he went. He liked to lead a gay and untroubled life, was fond of theatrical performances, satires and other intellectual diversions. His patronage of the fine arts, his genuine affection for Raphael, and the numerous works he caused to be executed by him and other artists, have served to confer an exaggerated glory on his name. He had not the remotest idea of the grave importance of the Reformation, which indeed he unconsciously promoted by his reckless and shameless sale of indulgences. The whole policy of Pope Leo X. consisted in oscillating between France and Spain, in always playing fast and loose, and deceiving both powers in turn. Yet the evil results of this contemptible policy never seemed to disturb his mind. He finally joined the side of the emperor Charles V., and in 1521, at the time of the defeat of the French by the Spanish troops on the river Adda, he ceased to breathe at his favourite villa of Magliana.

Giuliano dei Medici had died during Leo's reign, in 1516, without having ever done anything worthy of record. He was the husband of Philiberta, daughter of a natural son, Ippolito dei Medici (1511-1533), who afterwards became a cardinal. Lorenzo, being of more ambitious temper, was by no means content to remain at the head of the Florentine government hampered by many restrictions imposed by republican institutions, and subject to the incessant control of the pope. In his eagerness to aggressize his kinsmen, the latter had further decided to give Lorenzo the duchy of Urbino, and formally invested him in its rights, after expelling on false pretences its legitimate lord, Francesco Maria della Rovere. This prince, however, soon returned to Urbino, where he was joyously welcomed by his subjects, and Lorenzo regained possession only by a way of several months, in which he was wounded. In 1519 he also died, worn out by disease and excess. By his marriage with Madeleine de la Tour d'Auверgne, he had one daughter, Caterina dei Medici (1519-1588), married in 1533 to Henry, duke of Orleans, afterwards king of France. She played a long and sinister part in the history of that country. Lorenzo also left a natural son named Alessandro, inheriting the frizzled hair and projecting lips of the negro or mulatto slave who had given him birth. His miserable death will be presently related. Thus the only three surviving representatives of the chief branch of the Medici, Cardinal Giulio, Ippolito and Alessandro were all of illegitimate birth, and left no legitimate heirs.

Cardinal Giulio, who had laboured successfully for the reinstatement of his family in Florence in 1512, had been long attached to the person of Leo X., as his trusted factotum and companion. He had been generally regarded as the mentor of the pope, who had no liking for hard work. But in fact, his frivolity notwithstanding, Leo X. always followed his own inclinations. He displayed an aptitude for command, and pursued his shuffling policy without any mental anxiety. Giulio, on the contrary, shrank from all responsibility, muddled his brains in weighing the reasons for and against every possible decision, and was therefore a better tool of government in others' hands than he was fit to govern on his own account. When Giuliano and Lorenzo died, the pope appointed the cardinal to the government of Florence. In that post, restricted within the limits imposed by republican institutions, and acting under the continual direction of Rome, he performed his duties fairly well. He cared for the citizens with hopes of extended liberties, which, although never destined to be fulfilled, long and left served to keep men's minds in a pleasant flutter of expectation; and when the more impatient spirits attempted to raise a rebellion he speedily quenched it in blood. When, after the death of Leo X. and the very brief pontificate
of Adrian VI, he was elected pope (1523) under the name of Clement VII, he entrusted the government of Florence to Cardinal Silvio Passerini conjointly with Alessandro and Ippolito, who were still too young to do much on their own account. The pontificate of Leo X. had been a time of felicity to himself if of disaster to Italy and the Church. The reign of Clement, on the contrary, was fatal to himself as well. His policy, like that of Leo X., consisted in perpetual oscillation between France and Spain. By his endeavours to trick all the world, he frequently ended in being tricked himself. In 1525 he was the ally of the French, who then suffered a terrible defeat at Pavia, where their king Francis I. was taken prisoner. The armies of Charles V. triumphantly advanced, without Clement being able to oppose any effectual resistance. Both Rome and Florence were threatened with a federal government.

Thus far we have had no occasion to speak of the younger branch of the Medici, descended from Lorenzo, brother to Cosimo the elder. Always in obscurity, and hitherto held in check by the elder line, it first entered the arena of history when the other was on the point of extinction. In fact the most valiant captain of the papal forces was Giovanni del Medici, afterwards known by the name of Giovanni delle Bande Nere. His father was Giovanni, son of Pier Francesco, who was the son of Lorenzo, the brother of Cosimo del Medici. History has little to tell of the elder Giovanni; but his wife Caterina Sforza, of whom he was the third husband, was a woman of more than human power. Giovanni del Medici married her in 1497, but died in 1498, leaving her with one son who was christened Lodovico, but afterwards took his father's name of Giovanni (1498-1526). Trained to arms from his earliest years, this youth inherited all the energy of his mother, whose Sforza blood seemed to infuse new life into the younger branch of the Medici. Notwithstanding his extreme youth, he had already achieved the title of the best captain in Italy. He had always fought with immense dash and daring, and was devoted by love and abhorred by his soldiery. He was the only leader who opposed a determined resistance to the imperial forces. He was so seriously wounded at Pavia when fighting on the French side. On his recovery he joined the army of the League, and was much enraged by finding that the duke of Urbino, commander of the Venetian and papal forces, would never decide on attacking. When the imperial troops were struggling through the marshes of Mantua, surrounded on every side, and without stores or ammunition, Giovanni could not resign himself to inactivity like his colleagues in command. He was ignorant that the imperialists had just received supplies and artillery from the duke of Ferrara, and therefore determined to attack them with a small body of men without taking any precautions for defence. One of the first shots fired by the enemy injured him so fatally that he died a few days after.

He was married to Maria Salvati, by whom he had one son, Cosimo (1519-1574), who became the first grand duke of Tuscany, and indeed the founder of the grand duchy and the new dynasty.

Meanwhile the imperial army pursued its march upon Rome, captured the Eternal City after a few hours' combat, and cruelly sacked it during many days (1527). Sforza and his people, shuffling and excessive avarice, the pope found himselfe utterly forsaken, and was obliged to seek refuge in the castle of St. Angelo, whence he only effected his escape after some months. He then signed a treaty of alliance with the emperor (1529), who sent an army to besiege Florence and restore the Medici, whom the people had expelled in 1527 on the re-establishment of the republic. After an heroic defence, the city was forced to surrender (1530); and, although it was expressly stipulated that the ancient liberties of Florence should be respected, every one foresaw that the conditions would be violated. In fact, pope and emperor immediately began to dispute as to which should be the new lord of the city. Clement VII. had inherited the traditional family dislike for the younger branch of his kin, and so the choice lay between the two bastards Ippolito and Alessandro. The former being a cardinal, the latter was chosen. Alessandro, who already bore the title of duke of Città di Penna, came to Florence in 1531, and by imperial patent was nominated head of the republic. According to the terms of this patent, the former liberty enjoyed under the Medicean rule was to remain intact. But no previous ruler of the city had enjoyed such a patent, and such power was incompatible with the existence of a republic. Moreover, Clement VII. showed dissatisfaction with the uncertainty of the power conferred upon his kinsman, and finally succeeded in obtaining additional privileges. On the 4th of April 1532 a parliament was convoked for the last time in Florence, and, as usual, approved every measure proposed for acceptance. Accordingly a new council was formed of two hundred citizens elected for life, forty-eight of whom were to constitute a senate. Alessandro, as duke of the republic, filled the post of gonfalonier, and carried on the government with the assistance of three senators, changed every three months, who took the place of the suppressed signory.

The duke's chief advisers, and the contrivers of these arrangements were Baccio Valori, Francesco Vettori and above all Francesco Guicciardini—men, especially the latter two, of lofty political gifts and extensive influence. The mind and character of Duke Alessandro were as yet comparatively unknown. At first he seemed disposed to rule with justice and prudence. But encountering difficulties that he was unable to overcome, he began to neglect the business of the state, and acted as if the sole function of government consisted in lulling the people by festivities and corrupting it by the dissolute life of which he set the example. The question of the moment was the transformation of the old republican régime into a princedom; as an unavoidable result of this change it followed that Florence was no longer to be the ruling city to whose inhabitants alone belonged the monopoly of political office. When the leading Florentine families realized not only that the republic was threatened, but that they were reduced to equality with those whom they had hitherto regarded as their inferiors and subjects, their rage was indescribable, and hardly a day passed without the departure of influential citizens who were resolved to achieve the overthrow of their new rulers. They found a leader in Cardinal Ippolito dei Medici, who was then in Rome, embittered by the preference given to Alessandro, and anxious to become his successor with the least possible delay. Under the pressure of terror the duke at once became a tyrant. He garrisoned the different cities, and began the erection in Florence of the Fortezza da Basso, built chiefly for the accommodation of Filippo Strozzi, who afterwards met his death within its walls.

In 1534 Clement VII. died, and the election fell on Paul III., from whom Cardinal Ippolito hoped to obtain assistance. Accordingly the principal Florentine exiles were despatched to Charles V. with complaints of Alessandro's tyranny and his shameless violation of the terms upon which the city had surrendered. Cardinal Ippolito also represented his own willingness to carry on the government of Florence in a more equitable manner, and promised the emperor a large sum of money. Reply being delayed by the emperor's other commitments, so impatient that he set out to meet Charles in Tunis, but on the 20th of August 1535 died suddenly at Itri, poisoned by order of Alessandro. Such at least was the general belief, and it was confirmed by the same fate befalling other enemies of the duke about the same time. On the emperor's return from Africa, the exiles presented themselves to him in Naples, and the venerable patriot Jacopo Nardi pleaded their cause. Duke Alessandro, being cited to appear, came to Naples accompanied by Francesco Guicciardini, who by speaking in his defence rendered himself odious to all friends of liberty, and irretrievably tarnished his illustrious name. The cardinal being dead, it was hard to find a successor to Alessandro. On this account, and perhaps to some extent through the emperor's personal liking for the duke, the latter rose higher than before in the imperial favour, married Margaret of Austria, the natural daughter of Charles,
and returned to Florence with increased power. And now Alessandro indulged unchecked in the lowest excesses of tyranny, and although so recently a bridegroom gave way to increased libertinism. His whole time was passed in vicious haunts and in scandalous adventures. In order to conceal the obscurity of his birth, he left his mother to starve, and it was even asserted that he finally got rid of her by poison.

His constant associate in this disgraceful routine was his distant kinsman Lorenzo, generally known as Lorenzino dei Medici. Of the younger branch of the Medici, the latter was second cousin of the Cosmo already mentioned as the son of Giovanni delle Bande Nere. He had much culture and literary talent, but led an irregular life, sometimes acting like a madman and sometimes like a villain. He was a writer of considerable elegance, the author of several plays, one of which, the *Arilostia*, was held to be among the best of his age, and he was a worshipper of antiquity. Notwithstanding these tastes, when in Rome he knocked off the heads of some of the finest statues of the age of Adrian, an act by which Clement VII. was so incensed that he threatened to have him hanged. Thereupon Cosmo fled, and in Florence he became the friend of Duke Alessandro, and his partner in the most licentious excesses. They went together to houses of ill-fame, and violated private dwellings and convents. They often showed themselves in public mounted on the same horse. All Florence eyed them with disgust, but no one foresaw the tragedy that was soon to take place.

On the evening of the 5th of January 1537, after a day passed in the usual excesses, Lorenzino led the duke to his own lodging, and left him there, promising shortly to return with the wife of Leonardo Ginori. Alessandro, worn out by the exertions of the day, fell asleep on the couch awaiting Lorenzino's return. Before long the latter came accompanied by a desperado known as the Scorzonconcolo, who aided him in falling on the sleeper. Roused by their first thrusts, the duke fought for his life, and was only despatched after a violent struggle. The murderers then lifted the body into a bed, hid it beneath the clothes, and, Lorenzino having attached a paper to it bearing the words *vincit amor patris, taudumque immensus cupido*, they both fled to Venice. In that city Lorenzino was assassinated some ten years later, in 1548, at the age of thirty-two, by order of Alessandro's successor.

He wrote an *Apologia*, in which he defended himself with great skill and eloquence, saying that he had been urged to the deed solely by love of liberty. For this reason alone he had followed the example of Brutus and played the part of friend and courtier. The tone of this *Apologia* is so straightforward, sometimes even so eloquent and lofty, that we should be tempted to give it credence were it possible to believe the assertions of one who not only by his crime but by the infamy of his previous and subsequent career completely gave the lie to his vaunted nobility of purpose. By Alessandro's death the elder branch of the Medici became extinct, and thus the appearance of the younger line was heralded by a bloody crime.

When the duke's absence from his own palace was discovered on the morning of the 6th of January he was at first supposed to have spent the night with one of his mistresses; but soon, some alarm being felt, search was made, and Cardinal Cybo was the first to discover the murder. Enjoining the strictest secrecy, he kept the corpse concealed for three days, and then had it interred in the sacristy of San Lorenzo. Meanwhile he had hastily summoned Alessandro Vitelli and the other captains, so that, by the time Alessandro's death was made public, the city was already filled with troops. The cardinal then convened the council of forty-eight to decide upon a successor. Alessandro's only issue was a natural son named Giulio, aged five. The cardinal favoured his election, in the hope of keeping the real sovereignty in his own hands. But he speedily saw the impossibility of carrying out a design that was ridiculed by all. Guicciardini, Veitori and others of the leading citizens favoured the choice of Cosimo, the son of Giovanni delle Bande Nere. He was already in Florence, was aged seventeen, was keen-witted and aspiring, strong and handsome in person, heir to the enormous wealth of the Medici, and, by the terms of the imperial patent, was Alessandro's lawful successor. Charles V. approved the nomination of Cosimo, who without delay seized the reins of government with a firm grasp. Like Alessandro, he was named head of the republic; and Guicciardini and others who had worked hardest in his cause hoped to direct him and keep him under their control. But Cosimo soon proved that, his youth notwithstanding, he was resolved to rule unshackled by republican forms and unresisted in the disposal of acts under his control. The Florentines had now an absolute prince who was likewise a statesman of eminent ability.

On learning the death of Alessandro and the election of Cosimo, the exiles appreciated the necessity for prompt action, as delay would be fatal to the overthrow of the Medicean rule. They had received money and promises from France; they were strengthened by the adhesion of Filippo Strozzi and Baccio Valori, who had both become hostile to the Medici through the infamous conduct and mad tyranny of Alessandro; and Strozzi brought them the weapon of his own. Fortune and the prowess of the Medici had now an absolute prince who was likewise a statesman of eminent ability.

All the prisoners, who were members of great families, were brought before Cosimo, and were received by him with courteous coldness. Soon, however, a scaffold was erected in the Piazza, and on four mornings in succession four of the prisoners were beheaded. Then the duke saw fit to stay the executions. Baccio Valori, however, and his son and nephew were beheaded on the 20th of August in the courtyard of the Bargello. Filippo Strozzi still survived, confined in the Fortezza da Basso, that had been built at his expense. His family was illustrious, he had numerous adherents, and he enjoyed the protection of the French king. Nevertheless Cosimo only awaited some plausible pretext to rid himself of this dreaded enemy. He brought him to trial and had him put to the question. But this cruelty led to nothing, for Strozzi denied every accusation and bore the torture with much fortitude. On the 15th of December he was found dead in his prison, with a blood-stained sword by his side, and a slip of paper bearing these words: *exorare aliquis nostris ex ossibus ultra*. It was believed that, having renounced all hope of his life being spared, Strozzi had preferred suicide to death at the hands of the executioner. Some, however, thought that Cosimo had caused him to be murdered, and adopted this mode of concealing the crime. The young prince's cold-blooded massacre of his captives cast an enduring shadow upon his reign and dynasty. But it was henceforward plain to all that he was
a man of stern resolve, who went straight to his end without scruples or half-measures. Before long he was regarded by many as the incarnation of Machiavelli's *Principe*, "insatiable"; he joined daring to violent and prudence, was capable of great cruelty, and yet could practise mercy in due season." Guicciardini, who still pretended to act as mentor, and who on account of his many services had a certain influence over him, was obliged to withdraw from public life and busy himself with writing his *History* at his villa of Arceti. He died in this retreat in 1540, and it was immediately rumoured that the duke had caused him to be poisoned. This shows the estimation in which Cosimo was now held. He punished with death all who dared to resist his will. By 1540 sentence of death had been pronounced against four hundred and thirty contemptuous fugitives, and during his reign one hundred and forty men and six women actually ascended the scaffold, without counting those who perished in foreign lands by the daggers of his assassins. He reduced the old republican institutions to empty forms, by making the magistrates mere creatures of his will. He issued the sternest edicts against the rebels, particularly by the law known as the "Polverina," from the name of its proposer Jacopo Polverini. This law decreed not only the confiscation of the property of exiles, but likewise that of their heirs, even if personally acquired by the latter. Cosimo ruled like the independent sovereign of a great state, and always showed the capacity, firmness, and courage demanded by that station. Only, his state being small and weak, he was forced to rely chiefly upon his personal talent and wealth. It was necessary for him to make heavy loans to the different European sovereigns, especially to Charles V., the most rapacious of them all, and to give numerous bribes to their ambassadors. Besides, he had to carry on wars for the extension of his dominions; and neither his inherited wealth nor the large sums gained by confiscating the estates of rebellious subjects sufficed for all this outlay. He was accordingly compelled to burden the people with taxes, and thus begin at once to diminish its strength.

Cosimo bore a special grudge against the neighbouring republics of Siena and Lucca. Although the latter was small and weak, and the former garrisoned by Spaniards, yet the spectacle of free institutions at the frontiers of his own state served as a continual incitement to subjects disaffected to the new régime. In fact Francesco Burlamacchi, a zealous Lucchese patriot, had conceived the design of re-establishing republican government in all the cities of Tuscany. Cosimo, with the emperor's help, succeeded in having him accused and tried as an insignificant state making no pretence of rivalry, whereas Siena was an old and formidable foe to Florence, and had always given protection to the Florentine exiles. It was now very reluctantly submitting to the presence of a Spanish garrison, and, being stimulated by promises of prompt and efficacious assistance from France, rose in rebellion and expelled the Spaniards in 1552. Cosimo instantly wrote to the emperor in terms that appealed to his pride, asked leave to attack Siena, and begged for troops to ensure the success of his enterprise. As no immediate answer arrived, he feigned to begin negotiations with Henry II., but his cunning was at last discovered, and he obtained a contingent of German and Spanish infantry. Siena was besieged for fifteen months, and its inhabitants, aided by the valour of Piero Strozzi, who fought under the French flag, made a most heroic resistance, even women and children helping on the walls. But fortune was against them. Piero Strozzi sustained several defeats, and finally the Sienese, having exhausted their ammunition and being decimated by famine and the sword, were obliged to capitulate on honourable terms that were shamelessly violated. By the varied disasters of the siege and the number of fugitives the population was reduced from forty to eight thousand inhabitants. The republicans, still eager to resist, withdrew to Montalcino. Cosimo now ruled the city and territory of Siena in the name of Charles V., who always refused him his absolute possession. After the emperor's abdication, and the succession of Philip II. to the Spanish throne, Cosimo at last obtained Siena and Porto Ferroia by giving up his claim to a sum of 200,000 ducats that he was to have received from Charles V.

In 1559 Cosimo also captured Montalcino, and thus formed the grand-duchy of Tuscany, but he continued to govern the new state—i.e. Siena and its territories—separately from the old. His rule was intelligent, skilful and despotic; but his enormous expenses drove him to raise large sums of money by special contrivances unsuited to the country and the people. Hence, notwithstanding the genius of its founder, the grand-duchy held from the first the elements of its future decay. Cosimo preferred to confer office upon men of humble origin in order to have pliable tools, but he also liked to be surrounded by a courtier aristocracy on the Spanish and French pattern. As an added risk, he longer existed, he created new nobles, and tempted foreign ones to come by the concession of various feudal privileges; and, to turn this artificial aristocracy to some account, he founded the knightly order of St Stephen, charged with the defence of the coast against pirates, which in course of time won much honour by its prowess. He also established a small standing army for the protection of his frontiers; but he generally employed German and Spanish troops for his wars, and always had a foreign bodyguard. At the commencement of his reign he opposed the popes in order to maintain the independence of his own state; but later, to obtain help, he truckled to them in the same manner for the extent of giving up to the Inquisition his own confidant, Piero Carnesecchi, who, being accused of heresy, was beheaded and burnt in 1567. In reward for these acts of submission, the popes showed him friendship, and Pius V. granted him the title of grand-duke, conferring the patent and crown upon him in Rome, although the emperor had always withheld his consent. The measure most injurious to Tuscany was the fiscal system of taxes, of which the sole aim was to extort the greatest possible amount of money. The consequent damage to industry, commerce and agriculture was immense, and, added to the devastations caused by the Siensese War, led to their utter ruin. Otherwise Cosimo did not neglect useful measures for the interior prosperity of his state. He was no Maecenas; nevertheless he restored the Pisan university, enlarged that of Siena, had the public records classified, and also executed public works like the Santa Trinità bridge. During the great inundations of 1557 he turned his whole energy to the relief of the sufferers.

In 1559 he had espoused Eleonora of Toledo, daughter of the viceroy of Naples, by whom he had several children. Two died in 1563, and their mother soon followed them to the grave. It was said that one of these boys, Don García, had murdered the other, and then been killed by the enraged father. Indeed, Cosimo was further accused of having put his own wife to death; but neither rumour had any foundation. He now showed signs of illness and failure of strength. He was not old, but worn by the cares of state and self-indulgence. Accordingly in 1564 he resigned the government to his eldest son, who was to act as his lieutenant, since he wished to have power to resume the sceptre on any emergency. In 1570, by the advice of Pope Pius V., he married Camilla Martelli, a young lady of whom he had been enamoured for many years, and, added to the devations caused by the Siensese War, led to their utter ruin. himself like a vassal at Austria's feet. He reapèd his reward by
obtaining from Maximilian II, the title of grand-duke, for which
Cosimo had never been able to win the imperial sanction, but
he forfeited all independence. Towards Philip II. he showed
even greater subserviency, supplying him with large sums of
money wrung from his overtaxed people. He held entirely
aloof from France, in order not to awake the suspicions of his
protector at courted on his own account, thus conferring so
monopoly that was ruinous to the country. He raised the tax
upon corn to so high a rate that few continued to find any profit
in growing it, and thus the Maremme, already partly devastated
during the war with Siena, were converted into a desert. Even
industry declined under this system of government; and,
although Francesco founded porcelain manufactories and pietra
dura works, they did not rise to any prosperity until after his
deth. His love of science and letters was the only Medicean
virtue that he possessed. He had an absolute passion for
chemistry, and passed much of his time in his laboratory. Some-
times indeed he gave audience to his secretaries of state standing
before a furnace, bellows in hand. He took some useful measures
to promote the rise of a new city at Leghorn, which at that time
had only a natural and ill-sheltered harbour. The improvement
of Leghorn had been first projected by Cosimo I., and was
carried on by all the succeeding Medici. Francesco was a slave
to his passions, and was led by them to scandalous excesses and
deeds of bloodshed. His example and neglect of the affairs of
the state soon caused a vast increase of crime even among the
people, and, during the first eighteen months of his reign, there
occurred no fewer than one hundred and sixty-eight murders.

In default of public events, the historians of this period enlare
upon private incidents, generally of a scandalous or sanguinary
kind. In 1575 Orazio Pucci, wishing to avenge his father, whom
Cosimo had hanged, determined to get up a conspiracy, but,
soon recognizing how firmly the Medicean rule had taken root
in the country, desisted from the attempt. But the grand-duke,
on hearing of the already abandoned plot, immediately caused
Pucci to be hanged from the same window of the Palazzo
Vecchio, and even from the same iron stanchion, from which his
father before him had hung. His companions, who had fled
to France and England, were pursued and murdered by the ducale
emissaries. Their possessions were confiscated, and the “Pol-
verina” law applied, so that the conspirators’ heirs were reduced
to penury, and the grand-duke gained more than 300,000
ducats.

Next year Isabella dei Medici, Francesco’s sister, was strangled
in her nuptial bed by her husband, Paolo Giordano Orsini, whom
she had betrayed. Piero dei Medici, Francesco’s brother, mar-
ried his wife Eleonora of Toledo from the same motive. Still
louder scandal was caused by the duke’s own conduct.
He was already a married man, when, passing one day through
the Piazza of St Mark in Florence, he saw an exceedingly beautiful
woman at the window of a mean dwelling, and at once conceived
a passion for her. She was the famous Bianca Cappello, a
Venetian of noble birth, who had eloped with a young Florentine
named Pietro Buonaventuri, to whom she was married at the time
that she attracted the duke’s gaze. He made her acquaint-
ance, and, in order to see her frequently, nominated her husband
to a post in the council of state. Upon this Buonaventuri, with
much insolence, even to the nobility, that one evening he was
found murdered in the street. Thus the grand-duke, who was
thought to have sanctioned the crime, was able to indulge his
passion unchecked. On the death of the grand-duchess in 1578
he was privately united to Bianca, and afterwards married her
publicly. But she had no children, and this served to poison
her happiness, since the next in succession was her bitter enemy,
the cardinal Ferdinand. The latter came to Florence in 1587,
and was ostentatiously welcomed by Bianca, who was most
anxious to conciliate him. On the 15th of October of the same
year the grand-duke died at his villa of Poggio a Caiano, of a
fever caught on a shooting excursion in the Maremme, and the
next day Bianca also expired, having ruined her health by drugs
taken to cure her sterility. But rumour asserted that she had
prepared a poisoned tart for the cardinal, and that, when he
suspiciously insisted on the grand-duke tasting it first, Bianca
desperately swallowed a slice and followed her husband to the
tomb.

Such was the life of Francesco dei Medici, and all that can be
said in his praise is that he gave liberal encouragement to a few
artists, including de Giovanni Bolognà (1574). He was the
founder of the Uffizi gallery, of the Medicean theatre, and the villa
of Pratolino; and during his reign the Dellà Cruscé academy was
instituted.

Ferdinand I. was thirty-eight years of age when, in 1587, he
succeeded his brother on the throne. A cardinal from the age
of fourteen, he had never taken holy orders. He Ferdinand I.
showed much tact and experience in the manage-
ment of ecclesiastical affairs. He was the founder of the Villa
Medici at Rome, and the purchaser of many priceless works of
art, such as the Nèptne group, and many of her statues afterwards
transported by him to Florence. After his accession he retained
the cardinal’s purple until the time of his marriage. He was
in all respects his brother’s opposite. Affable in his manners
and generous with his purse, he chose a crestr typical of the
proposed mildness of his rule—a swarm of bees with the motto
Majestate tantum. He instantly pardoned all who had opposed
him, and left his kinsmen at liberty to choose their own place
of residence. Occasionally, for political reasons, he committed
acts unworthy of his character; but he re-established the adminis-
tration of justice, and sedulously attended to the business of the
state on the welfare of his subjects. Accordingly Tuscany was
revived under his rule and regained the independence and
political dignity that his brother had sacrificed to love of ease
and personal indulgence. He favoured commerce, and effectually
secured the prosperity of Leghorn, by an edict enjoining tolera-
tion towards Jews and heretics, which led to the settlement
of many foreigners in that city. He also improved the harbour
and facilitated communication with Pisa by means of the
Naviglio, a canal into which a portion of the water of the Arno
was turned. He nevertheless retained the reprehensive custom
of trading on his own account, keeping banks in many cities
of Europe. He successfully accomplished the draining of the
Val di Chiana, cultivated the plains of Pisa, Fucecchio and
Val di Nievole, and executed other works of public utility
at Siena and Pisa. But his best energies were devoted to the
foreign policy by which he sought to emancipate himself from
subjection to Spain. On the assassination (1586) of Henry III.
of France Ferdinand supported the claims of the king of Navarre,
undeterred by the opposition of Spain and the Catholic League,
who were dismayed by the prospect of a Huguenot succeeding
to the throne. Hence he was compelled to burden his subjects with
ever astonishing taxes, forgetting that while guaranteeing the
independence of Tuscany by his loans to foreign powers he was
increasingly sapping the strength of future generations. He
at last succeeded in obtaining the formal investiture of Siena,
which Spain had always considered a fief of her own.

During this grand-duke’s reign the Tuscan navy was notably
increased, and did itself much honour on the Mediterranean.
The war-galleys of the knights of St Stephen were despatched
to the coast of Barbary to attack Bona, the headquarters of
the corsairs, and they captured the town with much dash and
bravery. In the following year (1608) the same galleys achieved
their most brilliant victory in the archipelago over the stronger
fleet of the Turks, by taking nine of their vessels, seven hundred
prisoners, and jewels of the value of 2,000,000 ducats.

MEDICI (FAMILY)
 Ferdinand I. died in 1609, leaving four sons, of whom the eldest, Cosimo II., succeeded to the throne at the age of nineteen.  

**Cosimo II.** He was at first assisted in the government by his prudent mother and a council of regency. He had a good disposition, and the fortune to reign during a period when Europe was at peace and Tuscany blessed with abundant harvests. Of his rule there is little to relate. His chief care was given to the galleys of St Stephen, and he sent them to assist the Druses against the Porte. On one occasion he was involved in a quarrel with France. Concino Concini, the Marshal d'Ancre, being assassinated in 1617, Louis XIII. claimed the right of transferring the property of the murdered man to De Laynes. Cosimo, refusing to recognize the confiscation decreed by the French tribunals, demanded that Concini's son should be allowed to inherit. Hence followed much ill-feeling and mutual reprisals between the two countries, finally brought to an end by the intervention of the duke of Lorraine.  

Like his predecessors, Cosimo II. studied to promote the prosperity of Leghorn, and he deserves honour for abandoning all commerce on his own account. But it was no praiseworthy act to pass a law depriving women of almost all rights of inheritance. By this means many daughters of the nobility were driven into convents against their will. He gave scanty attention to the general affairs of the state. He was fond of luxury, spent freely on public festivities and doted on trouble. The state was apparently tranquil and prosperous; but the decay of which the seeds were sown under Cosimo I. and Ferdinando I. was rapidly spreading, and became before long patent to all and beyond all hope of remedy. The best deed done by Cosimo II. was the protection accorded by him to Galileo Galilei, who had removed to Padua, and there made some of his greatest discoveries. The grand duke recalled him to Florence in 1616, and nominated him court mathematician and philosopher. Cosimo died in February 1621. Feeling his end draw near, when he was only aged thirty and all his sons were still in their childhood, he hastened to arrange his large family and worldly affairs. His mother, Cristina of Lorraine, and his wife, Maddalena of Austria, were nominated regents and guardians to his eldest son Ferdinando II., a boy of ten, and a council of four appointed, whose functions were regulated by law. After Cosimo's death, the young Ferdinando was sent to Rome and Vienna to complete his education, and the government of Tuscany remained in the hands of two jealous and quarrelsome regents. Thus the administration of justice and finance speedily went to ruin. Out of subdivisioness the pope, the regents did not dare to maintain their legitimate right to inherit the duchy of Urbino. They continued to extort privileges on the new Tuscany nobility, which became increasingly insolent and worthless. They resumed the practice of trading on their own account, and, without reaping much benefit thereby, did the utmost damage to private enterprise.  

In 1627 Ferdinando II., then aged seventeen, returned to Italy and assumed the reins of government; but, being of a very gentle disposition, he decided on sharing his power with the regents and his brothers, and arranged matters in such wise that each was almost independent of the other. He galled the heads of the nobility by his great goodness and whims. Florence and Tuscany were ravaged by the plague in 1650, in which he showed admirable courage and carried out many useful measures. But he was totally incapable of energy as a statesman. When the pope made bitter complaints because the board of health had dared to subject certain monks and priests to the necessary quarantine, the grand-duke insisted on his officers asking pardon on their knees for having done their duty. On the death in 1631 of the last duke of Urbino, the pope was allowed to seize the duchy without the slightest opposition on the part of Tuscany. As a natural consequence the pretensions of the Roman curia became increasingly exorbitant; ecclesiastics usurped the functions of the state, added the ancient laws of the republic, together with the regulations decreed by Cosimo I. as a check upon similar abuses, were allowed to become obsolete. On the extinction of the line of the Gonzagas at Mantua in 1627, war broke out between France on the one side and Spain, Germany and Savoy on the other. The grand duke, uncertain of his policy, trimmed his sails according to events. Fortunately peace was re-established in 1631. Mantua and Monferrato fell to the duke of Nevers. Cosimo II. had always decided. But Europe was again in arms for the Thirty Years' War, and Italy was not at peace. Urban VIII. wished to aggrandize his nephews, the Barberini, by wresting Castro and Ronciglione from Odoardo Farnese, duke of Parma and brother-in-law to Ferdinando. Farnese marched his army through Tuscany into the territories of the pope, who was greatly alarmed by the attack. The grand-duke was drawn into the war to defend his own state and his kinsman. His military operations, however, were of the feeblest and often the most laughable character. At last, by means of the French intervention, peace was made in 1644. But, although the pope was forced to yield, he resigned none of his ecclesiastical pretensions in Tuscany. It was during Ferdinando's reign that the septuagenarian Galileo was obliged to appear before the Inquisition in Rome, which treated him with infamous cruelty. On the death of this great and unfortunate man, the grand-duke wished to erect a monument to him, but was withheld by fear of the opposition of the clergy. The dynasty as well as the country now seemed on the brink of decay. Two of the grand-duke's brothers had already died childless, and Ippolito, the sole survivor, was a canon. The only remaining heir was his son Cosimo, born in 1642.  

Like nearly all his predecessors, Ferdinando II. gave liberal patronage to science and letters, greatly aided therein by his brother Leopold, who had been trained by Galileo Galilei, and who joined with men of learning in founding the celebrated academy _Del Cimento_, of which he was named president. This academy took for its motto the words _Provando e riprovando_, and followed the experimental method of Galileo. Formed in 1657, it was dissolved in 1667 in consequence of the jealousies and dissensions of its members, but during its brief existence was renowned by the number and importance of its works.  

Cosimo III. succeeded his father in 1670. He was weak, vain, bigoted and hypocritical. In 1661 he had espoused Louise of Lorraine, niece of Louis XIV., who, being enamoured of duke Charles of Lorraine, was very reluctant to come to Italy, and speedily detested both her husband and his country, of which she refused to learn the language. She had two sons and one daughter, but after the birth of her third child, Giovann Gastone, her hatred for her husband increased almost to madness. She first withdrew to Poggio a Caiano, and then, survivor, was a cardinal. He resigned in 1679, and the Duke of Savoy in 1685, but did not die until 1686. Cosimo III. died in 1687.  

Cosimo's hypocritical zeal for religion compelled his subjects to multiply services and processions that greatly infringed upon their working hours. He wasted enormous sums in pensioning converts—even those from other countries—and in giving rich endowments to sanctuaries. Meanwhile funds often failed for the payment of government clerks and soldiers. His court was well supplied with dainties, but was poverty-stricken. He had no secretary, and, his table dainties for his table, adorned his palace with costly foreign hangings, had foreign servants, and filled his gardens with exotic plants. He purchased from the emperor the title of "Highness" in order to be the equal of the duke of Savoy. He remained neutral during the Franco-Spanish War, and submitted to every humiliation and requisition exacted by the emperor. He had vague notions of promoting agriculture, but accomplished no results. At one time he caused eight hundred families to be brought over from the Morea for the cultivation of the Maremma, where all of them died of fever. But when, after the revolution of the Edict of Nantes, French Huguenots offered to apply their labour and capital to the same purpose, the grand duke's religious scruples refused them refuge. So ruin fell upon Tuscany. Crime and misery increased, and the poor, who only asked for work, were given alms and sent often to church. This period
witnessed the rise of many charitable institutions of a religious character under the patronage of the grand-duke, as for instance the congregation of San Giovanni Battista. But these could not remedy the general decay.

Cosimo's dominant anxiety regarded the succession to the throne. His eldest son Ferdinand died childless in 1713. The pleasure-loving Giovanni Gastone was married to Anna Maria of Saxe-Lauenburg, widow of a German prince, a wealthy, coarse woman wholly immersed in domestic occupations. After living with her for some time in a Bohemian village, Giovanni Gastone yielded to his dislike to wife and country, withdrew to France, and ruined his health by his excesses. After a brief return to Bohemia he finally separated from his wife, by whom he had had no family. Thus the dynasty was doomed to extinction.

Cosimo the Elder, 1389-1464 = Contessina de' Bardi.

Piero, 1410-1469 = Lucrezia Tornabuoni, † 1462.

Giovanni, 1444-1469 = Ginevra degli Alessandri.

Giovanni II, Magnifico, 1449-1462 = Clarice Orsini, Giulia (Clement VI), 1459-1464.

Lorenzo, 1421-1492 = Anna Orsini, † 1479.

Lorenzo, 1449-1462 = Madeleine de la Tour d'Auvergne, † 1459.

Piero, 1417-1452 = Alfonso Orsini, † 1455.

Clarice, 1462-1469 = Filippo Strozzi, † 1452.

Giovanni, 1420-1452 = Leonardo da Vinci, † 1456.

Giovanni, 1459-1469 = Bicci, 1471-1479.

Lucia, 1469-1492 = Bicci, 1471-1479.

Infante of Portugal, 1451-1474 = Cirnáide de Portugal, 1454-1474.

Francesco, 1419-1458 = Anna Maria di Austria, 1439-1458.

Ferdinando I, 1422-1466 = Cristina di Lorraine, 1442-1466.

Isabella, 1438-1472 = Giovanni di Firenze, 1438-1472.

Virginia, 1438-1473 = Francesco I, 1438-1473.

Cosimo I, 1519-1574, = Eleonora di Toledo, 1522-1559.

Pier Francesco, † 1567 = Laodamia Acciaioli.

Giovanni, 1467-1469 = Caterina Sforza Riazzo, † 1500.

Giovanni delle Bande Nere, 1498-1520 = Maria Salviati, † 1520.

Cosimo I, 1519-1574, = Eleonora of Toledo, 1515-1522.

2. Camillo Martelli.

Ludovica, Maddalena = Pietro Strozzi, bishop of Bevera.

Cosimo II, 1590-1621 = Christina of Lorraine, 1598-1621.

Isabella, 1564-1629 = Giovanni di Firenze, 1564-1629.

Virginia, 1564-1629 = Caterina Gonzaga, duke of Mantua.

Giovanni Gastone was married to Anna Maria of Saxe-Lauenburg, † 1741.

Anna Maria Luisa, 1657-1743 = John William of the Palatinate.

Francesco Maria, 1600-1711 = Eleonora Gonzaga.

Francesco II, 1569-1621 = Christina of Lorraine, 1598-1621.

Anna Maria di Lorraine, 1597-1621 = Caterina Gonzaga, duke of Parma.

Cosimo II, 1590-1621 = Vittoria della Rovere, † 1621.

Ferdinando I, 1568-1621 = Cristina di Lorraine, 1598-1621.

Vittoria della Rovere.

In this way all things were in the hands of corrupt individuals; while the grand-duke, compelled to pass the greater part of his time in bed, vainly sought diversion in the company of buffoons, and was only tormented by perceiving that all the world disposed of his throne without even asking his advice. And when, after prolonged opposition, he had resigned himself to accept Don Carlos as his successor, the latter led a Spanish army to the conquest of Naples, an event afterwards leading to the peace of 1735, by which the Tuscan succession was transferred to Francesco II., duke of Lorraine, and husband of Maria Theresa. Giovanni Gastone was finally obliged to submit even to this. Spain withdrew her garrisons from Tuscany, and Austrian soldiers took their place and swore fealty to the grand-duke on the 9th of February 1737. He expired on the 9th of July of the same year. Such was the end of the younger branch of the Medici, which had found Tuscany a prosperous country, where art, letters, commerce, industry, and agriculture flourished,
MEDICI, G.—MEDICINE

and left her poor and decayed in all ways, drained by taxation, and oppressed by laws contrary to every principle of sound economy, downtrodden by the clergy, and burdened by a weak and vicious aristocracy.

MEDICI, GIACOMO (1817-1882), Italian patriot and soldier, was born at Milan in January 1817. Exiled in 1836, he fought in Spain in 1836 and 1837, and in 1839 joined Garibaldi at Montevideo. Returning to Italy with Garibaldi in 1848, he raised a company of volunteers to fight against Austria, and commanded the volunteer vanguard in Lombardy, proceeding thence to Rome, where he gained distinction by defending the "Vascello," a position near the Porta San Pancrazio, against the French. During the siege of Rome he himself was wounded. In the war of 1859 he commanded a volunteer regiment, and was sent by Cavour to Tirol. In 1860 he tried in vain to dissuade Garibaldi from the Marsala expedition, but, after his chief's departure, he sailed for Sicily with the second expedition, taking part in the storming of Messina, which he forced Messina to capitulate after an eight days' siege. Joining the regular army, he was appointed military commander of Palermo, in which capacity he facilitated the abortive campaign of Garibaldi in 1862. In 1866 he commanded the division which invaded Tirol, but the effect of his victories was neutralized by the conclusion of peace. Returning to Palermo he did good work in restoring order in Sicily. He became a senator in 1870, and marquis of the "Vascello" and first aide-de-camp to the king in 1876. He died on the 9th of March 1882.

MEDICINE.—The science of medicine, as we understand it, has for its province the treatment of disease. The word "medicine" (Lat. medicina: sc. ars, art of healing, from mederi, to heal) may be used very widely, to include Pathology (q.v.), the theory of the causation of disease, or, very narrowly, to mean only the drug or form of remedy prescribed by the physician—this being more properly the subject of Therapeutics (q.v.) and Pharmacology (q.v.). But it is necessary in practice, for historical comprehensiveness, to keep the wider meaning in view. Disease (see Pathology) is the correlative of health, and the word is not capable of a more penetrating definition. Further, the time of Galen, however, it has been usual to speak of the life of the body either as proceeding in accordance with the law of physical nature ( νάτα ἰσχύος, secundum naturam) or as overstepping the bounds of nature (πάθως φύσις, praeter naturam). Taking disease to be a deflexion from the line of health, the first requisite of medicine is an extensive and intimate acquaintance with the norm of the body. The structure and functions of the body form the subject of Anatomy (q.v.) and Physiology (q.v.).

The medical art (ars medendi) divides itself into departments and subdepartments. The most fundamental division is into internal (q.v.) and external (q.v.) medicine, or into medicine proper and surgery (q.v.). The treatment of wounds, injuries and deformities, with operative interference in general, is the special department of surgical practice (the corresponding parts of pathology, including inflammation, repair, and removable tumours, are sometimes grouped together as surgical pathology); and where the work of the profession is highly subdivided, surgery becomes the exclusive province of the surgeon, while internal medicine remains to the physician. A third great department of practice is formed by obstetric medicine or midwifery (see Obstetrics); and dentistry (g.v.), or dental surgery, is given up to a distinct branch of the profession.

A state of war, actual or contingent, gives occasion to special developments of medical and surgical practice (military hygiene and military surgery). Wounds caused by projectiles, sabres, &c., are the special subject of naval and military surgery; while under the head of military hygiene we may include the general subject of ambulances, the sanitary arrangements of camps, and the various forms of epidemic camp sickness.

The administration of the civil and criminal law involves frequent relations with medicine, and the professional subjects most likely to arise in that connexion, together with a summary of causes célèbres, are formed into the department of Medical Jurisprudence (q.v.).

In preserving the public health, the medical profession is again brought into direct relation with the state, through the public medical officers.

HISTORY OF MEDICINE

Medicine as Portrayed in the Homeric Poems.—In the state of society pictured by Homer it is clear that medicine has already had a history. We find a distinct and organized profession; we find a system of treatment, especially in regard to injuries, which it must have been the work of long experience to frame; we meet with a nomenclature of parts of the body substantially the same (according to Darenberg) as that employed long afterwards in the writings of Hippocrates; in short, we find a science and an organization which, however imperfect as compared with those of later times, are yet very far from being in their beginning. The Homeric heroes themselves are represented as having considerable skill in surgery, and as able to deal with ordinary wounds and injuries; there is also a professional class, represented by Machaon and Podalirius, the two sons of Asclepius, who are treated with great respect. It would appear, too, from the Aethiopis of Archinus (quoted by Welcker and Häsner) that the duties of these two were not precisely the same. Machaon's task was more especially to heal injuries, while Podalirius had received from his father the gift of "recognizing what was not visible to the eye, and tending what could not be healed." In other words, a rough indication is seen of the separation of medicine and surgery. Asclepius appears in Homer as a Thessalian king, not as a god, though in later times divine honours were paid to him. There is no sign in the Homeric poems of the subordination of medicine to religion which appears in the ancient Egyptian, where in Villeneuve the god Thot, in Heliopolis, and in the temple of the statue of Osiris, was in those countries, with medical functions—all circumstantial throw which grave doubts on the commonly received opinion that medicine derived its origin in all countries from religious observances.

Although the actual organization of medicine among the Homeric Greeks was thus quite distinct from religion, the worship of Asclepius (or Aesculapius) as the god of healing demands some notice. This cult spread very widely among the Greeks; it had great civil importance, and lasted even into Christian times; but there is no reason to attribute to it any special connexion with the development of the science of medicine. The profession of medicine, when it was first performed, was conveyed to the temples of Asclepius in order to be healed, just as in modern times relief is sought by a devotional pilgrimage or from the waters of some sacred spring, and then as now the healing influence was sometimes sought by deputy. The sick person, or his representative, after ablation, prayer and sacrifice, was made to sleep on the side of the sacrificial animal, or at the feet of the statue of the god, while sacred rites were performed. In his sleep (incubatio, insomnium) the body being regarded as indicated by a dream. Moral or dietetic remedies were more often prescribed than drugs. The record of the cure was inscribed on the columns or walls of the temple; and it has been thought that in this way was introduced the word "recovery," or "cure," and the word "physician of the Hippocratic school thus learnt to accumulate clinical experience. But the priests of Asclepius were not physicians. Although the latter were often called Asklepiads, this was in the first place to indicate their real or supposed descent from Asclepius, and in the second place as a complimentary title. No medical writing of antiquity speaks of the worship of Asclepius in such a way as to
imply any connexion with the ordinary art of healing. The two systems are, in fact, inconsistent with each other, and if they were ever united it must have been before the times of which we have any record. The theory of a development of Greek medicine from the rites of Asclepius, though defended by eminent moderns, is not supported by any positive evidence. It is, however, the theory of the influential and widely known text of Theophrastus, whose authorship has never been fully established; and he recognized, at least in acute diseases, a natural process which the humours went through—being first of all crude, then passing through coction or digestion, and finally being expelled from the system in the form of morbid or curative secretions from the body. The duty of the physician was to foresee these changes, as to assist or not to hinder them, so that "the sick man might conquer the disease with the help of the physician." The practice of the physicians was altogether in agreement with this theory, and was based on days fixed by certain numerical rules, in some cases on odd, in others on even numbers—the celebrated doctrine of "critical days." This false precision could have had no practical value, but it may have enforced habits of minute observation. It follows from what has been said that prognosis, or the art of foreseeing the course and event of the disease, was a strong point with the Hippocratic physicians. In this they have perhaps never been excelled. Diagnosis, or recognition of the disease, must have been necessarily imperfect, when no scientific nosology or system of disease existed, and the knowledge of anatomy was quite inadequate to a correct knowledge of the parts of the body the physician was called upon to assist. But symptoms were not doubt observed and interpreted skilfully. The pulse is not spoken of in any of the works now attributed to Hippocrates himself, though it is mentioned in other works of the collection.

In the treatment of disease, the Hippocratic school attached great importance to diet, the variations necessary in different diseases being minutely described. Medicines were regarded as of secondary importance, but not neglected, two names being mentioned at different places in the Hippocratic works. Blood-letting was known, but not greatly practised. The highest value was attached to the true observance of the time of operation, and the general principle enforced of making all influences internal and external—operate for the relief of the patient. The principles of treatment just mentioned apply more especially to the case of acute disease, but the account of the treatment of chronic diseases, the characteristic features of the Hippocratic school. In chronic cases diet, exercise, and natural methods were chiefly relied upon.

Hippocratic Medicine. The first grand characteristic of Hippocratic medicine is the high conception of the duties and status of the physician, shown in the celebrated "Oath of Hippocrates" and elsewhere—equally free from the mysticism of a priesthood and the vulgar pretensions of a mercenary craft. So mature a professional sentiment may perhaps have been more the growth of time and organization than the work of an individual genius, but certainly corresponds with the character universally attributed to the physician himself. The second great quality is the singular artistic skill and knowledge of the Hippocratic physician used such materials and tools as he possessed. Here we recognize the true Hippocratic method, which is the most striking feature of these first specimens of the profession of medicine. The cardinal virtue of Hippocratic medicine—the clear recognition of disease as being equally with life a process governed by what we should now call natural laws, which could be known by observation, and governed by the appointment of correct and normal regimen, by following which alone could the physician succeed. In the fourth place, these views of the "natural history of disease" (in the true language) led to habits of minute observation and accurate interpretation of the phenomena of disease, without undue regard to the age of Pericles, in which Hippocrates, already called "the Great," was in medicine as complete a representative of the highest efforts of the Greek intellect as were his contemporaries the great philosophers, orators and tragedians. The medical art as we now practise it, the character of the physician as we now understand it, both date for us from Hippocrates.

The justification of this statement is found in the literary collection of writings known by his name. Of these certainly many are falsely ascribed to the historical Hippocrates of Cos; others are authentic, and were doubtless the productions of those who carried on the works of his school, whether from his hand or not. But which are to be regarded as the "genuine works" is still uncertain, and authorities are conflicting. There are clearly two schools represented in the collection—that of Cnidus in a small proportion, and that of Cos in far the larger number of the works. The latter was that to which Hippocrates belonged, and where he gave instruction; and accordingly it may be taken that works of this school, when not obviously of a different date, are Hippocratic in doctrine if not in actual authorship.

There are clearly two schools represented in the collection—that of Cnidus in a small proportion, and that of Cos in far the larger number of the works. The latter was that to which Hippocrates belonged, and where he gave instruction; and accordingly it may be taken that works of this school, when not obviously of a different date, are Hippocratic in doctrine if not in actual authorship.

The actual science of the Hippocratic school of was of course very limited. In anatomy and physiology little advance had been made, and the philosophy of disease remained at a very low stage. The diagnosis of the diseases was necessarily more crude, or knowledge of diseased structures could be very little. The most valuable intellectual possession was a large mass of recorded observations in individual cases and epidemics of disease. Whether these observations were systematic or individual, and how they were recorded, are points of which we are quite ignorant, as the theory that the votive tablets in the temples supplied such materials must be rejected.

Though the Hippocratic medicine was so largely founded on observation, it would be an error to suppose that dogma or theory had no place. The dominating theory of disease was the humoral, which has never entirely ceased to be a fruitful theme in medical practice. According to this celebrated theory, the body contains four humours—blood, phlegm, yellow bile and black bile, a right proportion of which constitute health; improper proportions or irregular distribution, disease. It is doubtful whether the treatise in which this theory is fully expounded (text frænas deprocessus) is as old as Hippocrates himself; but it was regarded as a Hippocratic work, and was, according to some, the origin of the system of the four humours which has been used by medical men from the earliest times, and which are still an essential part of medical science. It is an ancient and still valuable guide to the human economy. Among his engravings are some on medical subjects, of which fragments only have been preserved. The Peripatetic school may have been more advanced in the study of anatomy than the Hippocratic, but was much inferior in the study of natural knowledge, than any other; but there is no evidence that any of the philosophical schools had important influence on the progress of medicine. The fruit of Aristotle's teaching and example was a more careful study of medical theory, and the more exact knowledge of the human anatomy and physiology which has been made progress; and which, by the help of the living expert to the study of the dead, is now so much advanced. The century after the death of Hippocrates is a time almost blank in medical annals. It is probable that the science, like others, took a step forward with the general intellectual development of Greece; but there is no evidence of any system or school in medical science in the time of Plato and Socrates. The century following was a time of stagnation, and the arts of physicians of the period are almost entirely lost, and were so even in the time of Galen. Galen classes them all as of the dogmatic school; but, whatever may be the case, the decline of the science has no record of importance in the history of the medical science.
Alexandrian School of Medicine.—The dispersion of Greek science and intellectual activity through the world by the conquests of Alexander and his successors led to the formation of more than one learned centre, in which medicine among other sciences was represented. Pergamum was early distinguished for its medical school; but in this as in other respects its reputation was ultimately effaced by the more brilliant fame of Alexandria. It is here that the real continuation and development of Hippocratic medicine can be traced.

In one department the Alexandrian school rapidly surpassed its Greek original,—namely, in the study of anatomy. The dissection of the human body, of which some doubtful traces or hints only are found in Greek times, was assiduously carried out, being favoured or even suggested perhaps by the Egyptian custom of disembowelling and embalming the bodies of the dead. There is no doubt that the organs were also examined by opening the bodies of living persons—criminals condemned to death being given over to the anatomists for this purpose.

Prominent names stand at the first rank as leaders of the two earliest schools of medicine which arose in Alexandria, Herophilus and Erasistratus.

Herophilus (335-280 b.c.) was a Greek of Chalcedon, a pupil of the schools both of Cos and of Cnidus. He was especially noted for his profound researches in anatomy (see i. 802), and in the knowledge and practice of medicine he appears to have been equally remarkable. He dissected himself of the various organs and adopted his theory of the humors. He also made extensive use of drugs and of bleeding. The reputation of Herophilus is attested by his many contemporaries, who wrote works about him and his writings, and he is further spoken of with the highest respect by Galen and Celsus. By the general voice of the medical world of antiquity he was placed second only to Hippocrates.

Erasistratus (d. 280 b.c.) was the contemporary and rival of Herophilus. Little is known of his life, except that he spent some time at the court of Seleucus Nicator at Antioch before coming to Alexandria, where he lived in isolation. He had taken up his abode in the latter city. His numerous works are also almost entirely lost, fragments only being preserved by Galen and others. Erasistratus, instead of following Hippocrates as Herophilus did, depreciated him, and seems to have been rather aggressive and independent in his views. He appears to have leaned to mechanical explanations of the symptoms of disease, as was especially the case with inflammation, of which he gave the first rational, though necessarily inadequate, theory.

The two schools composed of the followers of Herophilus and Erasistratus respectively long divided between them the medical world. The doctrines of both sects have been preserved, but it would be useless to repeat them. The Herophilists still reverenced the memory of Hippocrates, and claimed his sect as their own. From his works many eminent anatomists, but in the end seem to have become lost in theoretical subtleties, and to have maintained too high a standard of literary cultivation. The school of Erasistratus was less distinguished. It was attached to the Academy of Athens and was connected to the special symptoms of diseases, and employed a great variety of drugs. It was longer-lived than that of Herophilus, for it still numbered many adherents in the 2nd century after Christ, a century after the latter had become extinct.

The Erasistratians paved the way for what was in some respects the most important school which Alexandria produced, that known as the Hippocratic, which, though it recognized no master by name, may be considered to have been founded by Philinus of Cos (280 b.c.), a pupil of Herophilus; but Serapion, a great name in antiquity, and Galen of Tarentum, who traced the empirical doctrine back to the time of Hippocrates, may be more justly regarded as its leaders. The most striking peculiarity of the empiricists was that they rejected anatomy, regarding it as useless to inquire into the causes of things, and, thus as they contended, being the more minute in their observations. The whole of their teaching was based upon experience, to which word they gave a special meaning. Three sources, and three only, could experience draw from: 1. History; 2. Observation; and 3. Judgment by analogy. These three bases of knowledge were known as the "tripod" of the empirics. It should not, however, be forgotten that the empirics read and indifferently commented on the works of Hippocrates. They were extremely successful in practical matters, especially in surgery and in the use of drugs, and a large part of the routine knowledge of diseases and remedies which became traditional in the times of the Roman empire is believed to have been derived from the school of the empiricists. Treatment was given to the common diseases, which were closely connected with the philosophical sect of the Sceptics, whose leader, Sextus (200 b.c.), was an empirical physician. It lived and flourished far beyond this time, when transplanted to Rome, not less than in its native Alexandria, and appears to be recognizable even up to the beginning of the middle ages.

If we look at the work of the Alexandrian schools in medicine as a whole, we must admit that the progress made was great and permanent. The greatest service rendered to medicine was undoubtedly the systematic study of anatomy. It is clear that the knowledge of function (physiology) did not by any means keep pace with the rapid growth of knowledge of structure, and this was probably the reason why the Hippocratic sects were able entirely to dispense with anatomical knowledge. The doctrines of Hippocrates, though lightly thought of by the Erasistratians, still were no doubt very widely accepted, but the practice of the Hippocratic school had been greatly improved in almost every department—surgery and obstetrics being probably those in which the Alexandrian practitioners could compare most favourably with those of modern times. We have now to trace the fortunes of this body of medical doctrine and practice when transplanted to Rome, and ultimately to the whole Roman world.

Roman Medicine.—The Romans cannot be said to have at any time originated or possessed an independent school of medicine. They had from early times a very complicated system of superstitions, medicine, or religion, related to disease and the cure of disease, borrowed, as is thought, from the Etruscans; and, though the saying of Pliny that the Roman people got on for six hundred years without doctors was doubtless an exaggeration, and not, literally speaking, exact, it must be accepted for the broad truth which it contains. The empirical system and practice in which they lived, is, so far as we are able to trace it, as an importation from Greece.
MEDICINE

was knowledge spoken the Celsus dogma our more fact, some due the probability, Rome a treatment quoted modern the contraction if it was too far, and in the "mixed state" acting according to the predominant condition. This simple rule of treatment was the system or "method" from which the school took its name.

The methodists agreed with the empirics in one point, in their contempt for anatomy; but, strictly speaking, they were dogmatists, though of a different kind from the Hippocratic school. Besides Theismon, its systematic founder, the school boasted many physicians eminent in their day, among whom Theissalus of Troes, a hall-educated and boastful pretender, was the most prominent, though his "art is long," promising his scholars to teach them the whole of medicine in six months, and had inscribed upon his tomb horos, as being superior to all living and bygone physicians.

In general, much greater name appears to us under the methodists, that of Soranus of Ephesus, a physician mentioned with praise even by Tertullian and Augustine, who practised at Rome in the reigns of Trajan and Hadrian. Soranus is known by a work, still extant, entitled "Historia of the Diseases of Women," written by the Latin work of Caelius Aurelianus, three centuries later, on acute and chronic diseases, which is based upon, if not, as some think, an actual translation of, the chief work of Soranus, and which is the principal source of our knowledge of the methodic school. The work on diseases of women is the only complete work on that subject which has come down to us from antiquity, and shows remarkable fullness of practical knowledge in relation to its subject. It is notable that the principal instrument of research the school, which has been reinvented in modern times, was used by Soranus; and specimens of still earlier date, showing great mechanical perfection, have been discovered. The work of Soranus on acute and chronic diseases is also full of practical knowledge, but penetrated with the theories of the methodists.

The methodic school lasted certainly some centuries, and influenced medicine in the middle ages, overshadowed by the greater reputation of Galen. It was the first definite product of Greek medicine on Roman soil, but was destined to be followed by others, which kept up a more or less successful rivalry with it, and with the Hippocratic tradition.

The so-called pneumatic school was founded by Atheneus, in the first century after Christ. According to its doctrine the normal as well as diseased actions of the body were to be referred to the operation of the phlegm or universal soul. This doctrine, crudely translated, as "philosophical speculation, was intended to reconcile the humoral (or Hippocratic) and solidist (or methodic) schools; but the methodists seem to have claimed Atheneus as one of themselves.

It may be sufficient to name Rufus or Ephesus (2nd century A.D.), and Archigenes (fl. A.D. 90), who is mentioned by Juvenal.

Although no system or important doctrine of medicine was originated by the Roman intellect, and though the practice of the profession was probably almost entirely in the hands of the Greeks, the most complete picture which we have of medical thought and activity in Roman times is due to a Latin pen, and to one who was, in all probability, not a physician. A. Cornelius Celsus, a Roman patrician, who lived probably in the first century before Christ, wrote a work entitled "The Medical Art," an attempt to systematize medicine on the basis of general knowledge. Whether he was a practising physician or not has been a matter of controversy. The conclusion supported by most evidence seems to be that he practised on his friends and dependants, but not as a remunerative profession. His well-known work, De medicina, was one of a series of treatises intended to embrace all knowledge proper for a man of the world. It was not meant for the physicians, and was certainly little read by them, as Celsus is quoted by no medical writer, and when referred to by Pliny, is spoken of as an author not a physician. There is no doubt that his work is chiefly a compilation; and Darenberg, with other scholars, has traced a large number of passages of the Latin text to the Greek originals from which they were translated. In the description of surgical operations the vagueness of the language seems sometimes to show that the author had not performed such business; but in other parts, and especially in his historical introduction, he speaks with more confidence; and everywhere he compares and criticizes with learning and judgment. The whole body of medical literature belonging to the Hippocratic and Alexandrian times is ably summarized, and a knowledge of the state of medical science up to and during the times of the author is thus conveyed to us which can be obtained from no other source. The work of Celsus is thus for us only second importance to the Hippocratic writings and the works of Galen; but it is valuable rather as a part of the history of medicine than as the subject of that history. It forms no link in the general chain of medical tradition, for the simple reason that the influence of Celsus (putting aside a few scantly allusions in medieval times) commenced in the 15th century, when his works were first discovered in manuscript or committed to the press. Since then, however, he has been almost up to our own times the most popular and widely read of all medical classics, partly for the qualities already indicated, partly because he was one of the few of those classics accessible to reason. Later, and partly also for some of the reasons of the classical perfection of his language.

Of Pliny, another encyclopaedic writer, a few words must be said, though he was not a physician. In his Natural History we find as complete a summary of the popular medicine of his time as Celsus gives of the scientific medicine. Pliny disliked doctors, and lost no opportunity of depreciating regular medicine; nevertheless he has left many quotations from, and many details about, medical authors which are of the highest value. He is useful to us for what he wrote about the history of medicine, not for what he contributed. Like Celsus, he had little influence on medical opinion during one, though not perhaps the whole of his time.

We now come to the writer who, above all others, gathered up into himself the divergent and scattered threads of ancient medicine, and out of whom again the greater part of modern European medicine has flowed. Galen was a man furnished with all the anatomical, medical and philosophical knowledge of his time; he had studied all kinds of natural curiosities, and had stood in near relation to important political events; he possessed enormous industry, great practical sagacity and unbounded literary fluency. He had, in fact, every quality necessary for an encyclopaedic writer, and all the art and skill of a master craftsman."Galens medical profession of his time split up into a number of sects, medical science confined under a multitude of dogmatic systems, the social status and moral integrity of physicians degraded. He appears to have made it his object to reform these evils, to reconcile scientific acquisitions and practical skill, to bring back the unity of medicine as it had been understood by Hippocrates, and at the same time to raise the dignity of medical practitioners.

Galen was as devoted to anatomical and, so far as then understood, physiological research as to practical medicine. He worked enthusiastically at dissection, though, the liberty of the Alexandrian schools no longer existing, he could dissect only animals, not the human body. In his anatomical work he was the first to attempt a philosophical, to show the wisdom of the Creator in making everything fit to serve its purpose; and a practical, to aid diagnosis, or recognition, of disease. The first led him into a teleological speculative path which led him astray; the second was correctly attained by giving greater precision and certainty to medical and surgical practice in difficult cases. His general physiology was essentially founded upon the Hippocratic theory of the four elements, with which he combined the notion of spirit (pneuma) penetrating all parts, and mingled with the humours in different proportions. It was on this field that he most vehemently attacked the prevailing atomistic and materialistic views of the methodic school, and his conception of the pneuma became in some respects half metaphysical. His own researches in special parts of physiology were important, but do not strictly belong to our present subject.

The application of psychology to the explanation of diseases, and thus to practice, was chiefly by the theory of the temperaments or mixtures which Galen founded upon the Hippocratic doctrine of humours, but developed with marvellous and fatal ingenuity. The normal condition or temperament of the body depended upon a proper mixture or proportion of the four elements—cold, wet, and dry. From the four temperaments conception of the simple humours are derived the corpora humanae or facultates ("distemper"), which, though not diseases, were the occasions of disease. Equal importance attached to faulty mixtures or combinations of humours, and the disposition to disease from these dispositions with the action of deleterious influences from without all diseases were produced, Galen showed extreme ingenuity in explaining all symptoms and all diseases on his system. No pheno-

Phenomena was, without a name, probably the most useless of all his writings. And, though it was precisely in his fine-spin subtlety that he departed furthest from scientific method and practical utility, it was this very quality which saved his science and his writings, and ensured his popularity and established his pre-eminence in the medical world.

Galen's use of drugs was influenced largely by the same theories. In drugs were to be recognized the same elementary qualities—hot,
cured by contraries, the use of one or other was indicated. The writings of Galen contain less of simple objective observations than those of several other ancient physicians, all been swept into the current of historical events. He is also noted for his great thoroughness and extent of his practical knowledge. Unfortunately it was neither this nor his zeal for research that chiefly won him followers, but the completeness of his theoretical explanations, which fall in with the mental habits of succeeding centuries, and were such as have flattered the intellectual idolence of all ages. But the reputation of Galen grew slowly; he does not appear to have enjoyed any pre-eminance over the other physicians of his time, so far as the Arabs possessed themselves of the scattered remains of Greek culture, the works of Galen were more highly esteemed than any others except those of Aristotle. Through the Arabs the Galenical system found its way back again to western Europe. Even when Arabian medicine gave way before the direct teaching of the Greek authors rescued from neglect, the authority of Galen was increased instead of being diminished; and he assumed a position of autocracy in medical science which was only slowly undermined by the growth of modern science in the 17th and 18th centuries.

The history of medicine in Roman times is by no means the same thing as the history of the fate of the works of Galen. For some centuries the medical school was popular at Rome, and produced one physician, Caelius Aurelianus, who must be pronounced, next to Celsius, the most considerable of the Latin medical writers. His date was in all probability given by the 4th century, though he may have lived in the second half of the 1st century, and the beginning of the 3rd. His works have been much admired for the purity of the Greek style, and his accurate descriptions of disease; but, as he quotes no medical author, and is quoted by none before Alexander of Aphrodisias at the beginning of the 3rd century, it is clear that he belonged to no school and founded none, and thus his position in the chain of medical tradition is quite uncertain. Alexander of Aphrodisias, who lived and wrote at Athens in the time of Septimius Severus, is best known by his commentaries on Aristotle, but also wrote a treatise on fevers, still extant.

Ancient Medicine after Galen.—The Byzantine school of medicine, which is the continuation of the earlier schools, followed closely in Galen's footsteps, and its writers were chiefly compilers and encyclopaedists. The earliest is Orhasius (526-603), whose date and position are fixed by his being the friend and court physician of Julian the Apostate. He was a Greek of Pergamum, educated in Alexandria, and long resident in Byzantium. His great work Συναγωγα Ἰατρῶν, of which only about one-third has been preserved, was a medical encyclopaedia founded on Hellenic sources. Galen, Dioscorides (f. a. D. 50) and certain Greek writers who are otherwise very imperfectly known. This work is thus one of great historical value but of no originality. The most original character is Asclepiades of Tarentum (A.D. 550), a compiler who closely followed Orhasius, but with inferior powers, and whose work also has an historical but no original value. A higher rank among medical writers is assigned to Alexius of Paris (525-605), whose doctrine was that of an eclectic. His practical and therapeutical rules are evidently the fruit of his own experience, though it would be difficult to attribute to him any decided advance in medical knowledge.

The next figure is that of Paul of Aegina (Paulus Aegineta), who lived probably in the early part of the 7th century. His skill, especially in surgery, must have been considerable, and his influence great, for he is the author of the almost unique Greek compilation in the medical profession of the period, that of Donatus. He is also one of the chief members of the Greek medical school which the Arabs called the 'larpucai,' or a translation of the Greek word for a library; of course the name of the school was that of a medical school in Egypt. In this respect Paulus is a most important influence in the development of medicine. His great work on surgery was early translated into Arabic, and became the foundation of the surgery of Abulcasis, which in turn (to anticipate) was one of the chief sources of surgical knowledge to Europe in the middle ages. The succeeding period of Byzantine history was so little favourable to scientific progress that even the loss of one of the most valuable medical works of this period is still extant) till the 13th century, when we meet with a group of writers: Demetrius Pemagomenos, Nicolaus Myreppus and Johannes, called Actuarius, who flourished in the latter part of the 12th century, having been influenced by the Arab schools of medical learning. The fact is that some independent merit; but all are interesting as showing a fusion of Greek and Arabian medicine, the latter having begun to exercise a large influence, as the consequence of the rapid growth of Islam. Something was borrowed even from the school of Salerno, and thus the close of Byzantine medicine is brought into connexion with the dawn of science in modern Europe.

This period of the history of Arabian medicine affords little evidence of anything but a gradual though unvarying decline in Roman medicine. Caelius Aurelianus, already referred to as the follower of Soranus, must be mentioned as showing the persistence of the medical school. An abridgment of one of his writings, with the title of Aurelius, became the most popular of all Latin medical works. As a writer he was worthy of a better period of medical literature. Little else was produced in these times but compilations, of the most meagre kind, chiefly of the nature of herbalis, or original receipts; among the authors of which it is probable to name Serenus Sammonius (3rd century), Gargilinus Martialis (3rd century) and Isidore of Seville (5th century). The medical treatises extant bear the falsely-assumed names of eminent writers, such as Pliny and Hippocrates. A writer with the (perhaps) assumed name of Progymnasmeneus is said to have lived in the 4th century. He is probably a mixture of genuine and spurious material; these poor compilations, together with Latin translations of certain works of Galen and Hippocrates, formed a kind of literature, probably written in the Greek, which a part of the time survived through the middle ages till the discovery of printing and revival of learning. It is important to remember that this obscure stream of tradition flowed on, only partially affected by the progress of Arab, or even the early revival of purer classical learning.

Arabian Medicine.—The rise of the Mahomedan Empire, which influenced Europe so deeply both politically and intellectually, made its mark also in the history of medicine. As in the parallel case of the Roman conquest of Greece, the superior culture of the conquered race asserted its supremacy over their Arab conquerors. After the Mahomedan conquests became consolidated, and learning began to flourish, schools of medicine, often connected with hospitals and schools of pharmacy, arose in all the chief seats of Moslem power. At Damascus Greek medicine was zealously cultivated with the aid of Jewish and Christian teachers. In Bagdad, under the rule of Harun El Rashid and his successors, a still more flourishing school arose, where numerous translations of Greek medical works were made. The names of Mesoa, or Yalay ibn Masawaiah (d. A.D. 837-838), celebrated for his knowledge of drugs, and Iouene ibn Hasaq ibl Ibbi (d. 873) or Joannitus, the translator and commentator of Hippocrates and Galen, belong to this period. Certain writings of Joannitus, translated into Latin, were popular in the middle ages in Europe, and were printed in the 16th century. At the same time the Arabs became acquainted with Indian medicine, and Indian physicians lived at the court of Bagdad. The Islamic rulers in Spain were not long behind those of the East in encouraging learning and medical science, and developed culture to a still higher degree of perfection. In that country much was due to the Jews, who had already established schools in places which were afterwards the seats of Moslem dominion. From the 10th to the 13th century was the brilliant period of Arabian medicine in Spain.  

The classical period of Arabic medicine begins with Razes (Abû Bakr Muhammad ibn Zakariyâ el-Râzi, A.D. 925-926), a native of Rayy, to the province of Dughm (Persia), who practiced with distinction at Bagdad; he followed the doctrines of Galen, but learnt much from Hippocrates. He was the first of the Arabs to treat medicine by the influence of the causes, and attempted to substitute the doctrine of the causes for the doctrine of the signs, in voluminous Galen himself, though but a small proportion of his extant works is extant. Razes is deservedly remembered as having described small-pox and measles in an accurate manner. Hâj, son of Abu el-Mahmud, was the first writer who published a work known as the "Royal Book," which was the standard authority among the Arabs up to the time of Avicenna (A.D. 980-1037) and was more than once translated into Latin and printed. Other
writers of this century need not be mentioned here; but the next, the 11th century, is given as the probable though uncertain date of a work which had a great influence on medicine and derived from the Arabian, whose personality is obscure, and of whose existence some historians have doubted, thinking that the name was assumed by some medieval Latin writer. The work De significatione... had his name attached to it, and was given authority on what would now be called materia medica, was printed in twenty-six editions in the 15th century and later, and was used in the formation of the first London pharmacopoeia, issued by the College of Physicians. Over the reign of James I., or the 11th century must be referred the name of another Arabian physician who has also attained the position of a classic, Abu'Qalib, Ibn Zuhr (Ez-Zuhry). He is, Abū Merwān 'Abd al-Malik Ibn Zuhr (beginning of 12th century), a member of a family which gave several distinguished members to the medical profession. His chief work, Al-Teyyid (Facilitation), was thought to show more practical experience than the writings of Avicenna, and to be less based upon dialectical subtleties. It was translated into Latin, and more than once printed, as were some of his lesser works, which thus formed a part of the contribution made by the Arabs to European medicine. His friend and pupil Averroes of Cordova (q.e.), so well known for his philosophical writings, was also an author in medical subjects, and as such widely read in Latin. The famous Rabi' Maimonides (A.D. 1135-1204, q.v.) closes for us the role of medical writers of the Arabian school. His works exist chiefly in the original Arabic or in Hebrew translations. He wrote treatises on medicine and translated Greek works so that no definite opinion can be formed as to their medical value. But, so far as is known, the independent and rationalistic spirit which the two last-named writers showed in philosophy did not lead them away from the point of view of Arabian medicine.

The works of the Arabian medical writers who have now been mentioned form a very small fraction of the existing literature. There are many more writers in medicine who have contributed to the advancement of medicine, and who have been named or named in manuscripts by authors like Averroes and Witenfeld (1080-1089), and other historians have enlarged the list (Häser), but only three have been printed in the original; a certain number more are known through old Latin translations, and the great majority still exist in manuscript. It is evident that the circumstance of having been translated (which may have been in some cases almost an accident) is what has chiefly determined the influence of particular writers on Western medicine. But it is improbable that further research will alter the general estimate of the value of Arabian medicine. There can be no doubt that it was in the main Greek medicine, modified to suit other climates, that the Arabian system, and Arabic medicine, was derived from Oriental sources. The greater part is taken from Hippocrates, Galen, Dioscorides and later Greek writers. The Latin medical writers were necessarily unknown to the Arabs; and this was partly the cause of the imitation which they showed. Among the Greeks, in practical medicine nothing new can be traced, except the description of certain diseases (e.g. small-pox and measles) unknown or imperfectly known to the Greeks; the only real advance was in pharmacology. But in this field the Arab contributed much which is corrupt, and very inferior in value. They produced the first pharmacopoeia, and established the first apothecaries' shops. Many of the names and many forms of medicines now used, and in fact the general outline of modern pharmacy, except so far as modified by modern chemistry, started with the Arab. Thus the modern medicine, which is known as the Arabian, is the medicine of the 11th century, and not, as is sometimes supposed, the medicine of the 13th century. The Arabic medicine of the 11th century, partly because it was derived from the Greek, is the medicine of the Middle Ages, and under this term is known as the Arab or the Arabic; and it was this medicine which was first introduced into Europe in the 12th century. The establishment of the medicine of the 11th century in Europe at the end of the Western Empire and before the influence of Arabian science and literature began to be felt. This we may call the pre-Arabian or Saracen period.

**Medicine in the Early Middle Ages:** School of Salerno.—In medical as in civil history there is no real break. A continuous thread of learning and practice must have continued the last period of Roman medicine already mentioned with the dawn of science in the middle ages. But the intellectual thread is naturally traced with greater difficulty than that which is the theme of civil history; and in periods such as that from the 12th to the 14th century, it is almost lost. Some of the names of medical as of other learning in these disturbed times were the monasteries. Though the science was certainly not as advanced by their labours, it was saved from total oblivion, and many ancient medical works were preserved either in Latin or vernacular versions. The Anglo-Saxon Leechdoms 1 of the 11th century, published in the Rolls series of medieval chronicles and memorials, admirably illustrate the mixture of magic and superstition with the relics of ancient science which constituted monastic medicine. Similar works, in Latin or other languages, and belonging to the period of the European libraries. It was among the Benedictines that the monastic practice of medicine first received a new direction, and aimed at a higher standard. The study of Hippocrates, Galen, and other classics was recommended by Cassiodorus (6th century), and in the original mother-abbey of Monte Cassino medicine was studied; but there was not what could be called a medical school; nor had this foundation any connexion (as has been supposed) with the famous school of Salerno.

The origin of this, the most important source of medical knowledge in Europe in the early middle ages, is involved in obscurity. It is known that Salerno, a Roman colony, in a situation noted in ancient times for its salubrity, was in the 6th century at least the seat of a bishopric, and at the end of the 7th century of a Benedictine monastery, and that some of the prelates and higher clergy were distinguished for learning, and even for medical acquirements. But it has by recent researches been clearly established that the celebrated Schola salernitana was a purely secular institution. All that can with certainty be said is that a school or collection of schools gradually grew up in which especially medicine, but also, in a subordinate degree, law and philosophy were taught. At some time there must have been a demand for high-class medical instruction and training for the profession or for the hippocratica. A little later we find great and royal personages resorting to Salerno for the restoration of their health, among whom was William of Normandy, afterwards the Conqueror. The number of students of medicine must at one time have been considerable, and in a corresponding degree the number of teachers. Among the latter many were married, and their wives and daughters appear also in the lists of professors. The most noted female professor was the celebrated Trotula in the 12th century. She was not a professional medical woman, but appears to have been important among the students, and possibly among the staff of the school. The reputation of the school was great till the 13th or 14th century, when the introduction of the Arab medicine was gradually fatal to it. The foundation of the university of Naples, and the rise of Montpellier, also contributed to its decline.

The teachings of the Saracenic doctors are pretty well known through existing works, some of which have only recently been edited and published. The best-known is the following, a poem on health by Joannes de Meditano, Regimen sanitatis Salerni, personally written for the use of the "king of England," supposed to have been William the Conqueror; it had an immense reputation in the middle ages, and was afterwards many times printed, and translated into most European languages. This was a popular work intended for the laity; but there are others strictly professional.

---

1 Derived from the Anglo-Saxon *leacæ*, a physician, and *dom*., a law.
Among the writers it may be sufficient to mention here Gariopontus: Cephis, who wrote the *Anatome pori*, a well-known medical book; John of Ctesiphon (1124-1191), a Persian originally named Prosper, became known by the name, whose *Practica*, or medical compendium, was afterwards several times printed; and Trotula, believed to be the wife of the later 13th century physician and辙ient before the school of Arab medicine. In the transitional period, when the Arabian school began to influence European medicine, but before the Salernitans were superseded, comes Nicolaus Praepositus, who wrote the *Anathomia*, an encyclopedia of foreign and compound medicines, which became the standard work on the subject, and the foundation of many later compilations. An equally popular writer was Gilles de Corbeil (Agellius Corbolienis), at one time a teacher at Salerno, afterwards court physician to Philip Augustus of France, who composed several poems in Latin hexameters on medical subjects. Two of them, on the urine and the pulse respectively, attained the position of medical classics.

None of these Salernitan works rises much above the rank of compilations, being founded on Hippocrates, Galen and later Greek writers, with an unmistakable mixture of the doctrines of the methodists. But they often show much practical experience, and exhibit the naturalistic method of the Hippocratic school. The general plan of treatment is dietetic rather than pharmaceutical, though the art of preparing drugs had reached a high degree of complexity at Salerno. Anatomy was as little regarded as it was in the later ancient schools, the empiric and methodic, but demonstrations of the parts of the body were given on swine. Although it is clear that the Arabian school was the direct source of the Salerno, still its decline was arrested at a time when every other branch of learning was rapidly falling into decay; and there can be no doubt that the observation of patients in hospitals, and probably clinical instruction, were made use of in learning and teaching. The school of Salerno thus forms a bridge between the ancient and the modern medicine, more direct though less conspicuous than that circuitous route, through Byzantium, Bagdad and Cordova, by which medicine passed from Greece to India and thence to the Arab world. Through the glory of Salerno had departed, the school actually existed till it was finally dissolved by an edict of the emperor Napoleon I. in the year 1811.

**Introduction of Arabian Medicine: The Scholastic Period.**—About the middle of the 11th century the Arabian medical writers began to be known by Latin translations in the Western world. Constantinus Africanus, a monk; was the author of theearliest of such versions (A.D. 1063); his labours were directed chiefly to the less important and less bulky Arabian authors, of whom Haly was the most noted; the real classics were not introduced till later. For some time the Salernitan medicine held its ground, and it was not till the conquest of Toledo by Alphonso of Castile that any large number of Western scholars came in contact with the learning of the Spanish Moors, and systematic efforts were made to translate their philosophical and medical works. Jewish scholars, under the patronage of Christian bishops, were especially active in the work. In Sicily also the Oriental tendencies of Frederic Barbarossa and his court were reflected in the interest manifested in the translations. Cremona, a physician of Toledo (1114-1187), made translations, it is said by command of Barbarossa, from Avicenna and others. It is needless to point out the influence of the crusades in making Eastern ideas known in the Western world. The influence of Arabian medicine soon began to be felt even in the Hippocratic city of Salerno, and in the 13th century is said to have had an even balance with the older medicine. After this time the foreign influence predominated; and by the time that the Aristotelian dialectic, in the introduction of which the Arabs had so largely contributed, and the Latin literature was introduced, the Arabian version of Greek medicine reigned supreme in the medieval school. That this movement coincided with the establishment of some of the older European universities is well known. The history of medicine in the period now opening is closely combined with the history of scholastic philosophy. Both were infected with the same dialectical subtlety, which was, from the nature of the subject, especially injurious to medicine. At the same time, through the rise of the universities, medical learning was much more widely diffused, and the first definite forward movement was seen in the school of Montpellier, where a method of reasoning was introduced which more nearly united with faculties of law and philosophy. The medical school owed its foundation largely to Jewish teachers, themselves educated in the Moorish schools of Spain, and imbued with the intellectual independence of the Averroists. Its rising prosperity coincided with the decline of the school of Salerno. Montpellier became distinguished for the practical and empirical spirit of its medicine, as contrasted with the dogmatic and scholastic teaching of Paris and other universities. In Italy, Bologna and Padua were earliest distinguished for medical studies—the former preserving more of the Galenical tradition, the latter that of the progressive and Averroistic. The northern universities contributed little—the reputation even of Paris being of later growth.

The supremacy of Arabian medicine lasted till the revival of learning, when the study of the medical classics in their original language worked another revolution. The medical writers of this period, who chiefly drew from Arabian sources, have been called Arabists (though it is difficult to give any clear meaning to this term), and were afterwards known as the neoteries.

The medical literature of this period is extremely voluminous, but essentially second-hand, consisting mainly of compilations on Hippocrates, Galen, Avicenna and others, or of compilations and *compendia* still less original than commentaries. Among these may be mentioned the *Conciliorum* of Peter of Abano (1250-1315), the *Daguerreon* of Jacob de Dondi (1298-1350), both of the school of Padua, and the *Pandectae medicinae* of the Salernitan Matthaeus Sylvaricus (d. 1342), a sort of medical glossary and dictionary. But for us the most interesting fact is the first appearance of Englishmen in a medical capacity, and the emergence of a medical movement in English, distinguishuated, according to the testimony of Heser, by a practical tendency characteristic of the British race, and fostered in the school of Padua.

The first of these works is the *Compendium medicinae*, also called *Loreo* or *Rua angicana*, of Gilbertus Anglicus, about 1290, said to contain good observations on leprosy. A more important work, the *Practica seu lium medicinae*, of Bernard Gordon, a Scottish professor at Montpellier (written in the year 1307), was more widely spread, being translated into French and Hebrew, and printed in several editions. Of these two physicians the first probably, the latter certainly, was educated and practised abroad, and John Gaddessen (1250-1361), the author of *Rosa anglica seu practica medicinae* (between 1305 and 1317), was a graduate in the faculties of Montpellier, and in the character of a medical compiler. His *Anglica medicina* is an almost original compilation, and is distinguished by the character of learning, and is usually called the Englishman to the* compendium* is entirely wanting in originality, and perhaps unusually destitute of common sense, but it became so popular as to be reprinted up to the end of the 16th century. Works of this kind became still more abundant in the 14th and in the first half of the 15th century, till the wider distribution of the medical classics in the original put them out of fashion.

In surgery this period was far more productive than in medicine, especially in Italy and France, but the limits of our subject only permit us to mention Guido of Saliceto of Piacenza (about 1275), Lanfranchi of Milan (died about 1306), the French surgeon, Guy de Chauliac (1298-1368), Englishman, John of Yard (1350-1359), the first who is regarded as an original author in surgery, and the author of several treatises on wrestling. In anatomy also the beginning of a new epoch was made by Mondino de Liucii or Mundinus (1275-1326), and his followers. The medical writings of Arnold de Villanova (c. 1235-1315) (if the *Diagnos* and *Therapeuticon* written by his pupil, Dondi, are not the same work) are of importance as the first attempts at division of the subject. Finally, in the 14th and especially the 15th century we find, under the name of *consilia*, the first medical reports of medical cases which are preserved. The first such form is the *singular consilia* of the 15th century, Giliberto de Giacomo (about 1450). The *Period of the Revival of Learning.***—The impulse which all departments of intellectual activity received from the revival of Greek literature in Europe was felt by medicine among the rest. Not that the spirit of the Renaissance sought so much the methodical practice, was at once changed. The basis of medicine through the middle ages had been literary and dogmatic, and it was literary and dogmatic still; but the medical literature now brought to light—including as it did the more important works of Hippocrates and Galen, many of them hitherto unknown, and in addition the forgotten element of Latin medicine, especially the work of Celsius—was in itself far superior to the second-hand compilations and incorrect versions which had formerly been accepted as standards. The classical works, though still regarded with unreasoning reverence, were found to contain many errors; the spirit of learning was in the mind out of the region of dogma, and prepared the way for the scientific movement which has been growing in strength up to our own day.
Two of the most important results of the revival of learning were indeed such as are excluded from the scope of this brief sketch—namely, the reawakening of anatomy, which to a large extent grew out of the study of the works of Galen, and the investigation of medicinal plants, to which a fresh impulse was given by the revival of Dioscorides (A.D. 50) and other ancient naturalists. The former brought with it necessarily a more accurate conception of physiology, and thus led up to the great discovery of Harvey, which was the turning-point in modern medicine. The latter gave rise, on the one hand, to the modern science of botany, on the other to a more rational knowledge of drugs and their uses. At the same time, the Arabians supplied themselves by intercourse with the East, by introducing a variety of new plants, greatly accelerated the progress both of botany and pharmacology.

But it was not in these directions that improvement was first looked for. It was at first very naturally imagined that the simple revival of classical and especially of Greek literature would at once produce the same brilliant results in medicine as in literature and philosophy. The movement of reform started, of necessity, with scholars rather than practising physicians—more precisely with a group of learned men, whose members were predominantly humanists, chiefly from Italy, the medical humanists, equally enthusiastic in the cause of letters and of medicine. From both fields they hoped to expel the evils which were summed up in the word barbarism. Nearly all medieval medical literature was condemned under this name; and for it the humanists proposed to substitute the originals of Hippocrates and Galen, thus leading back medicine to its fountain-head. Since a knowledge of Greek was still confined to a small body of scholars, and a still smaller proportion of physicians, the first task was to translate the Greek classics into Latin. To this work several learned physicians, chiefly Italian and French, contributed, and it is said that nearly every one of them contributed to the task. Among the earliest were Nicolaus Leoncenuus of Vicenza (1428-1524), Giovanni de Monte or Montanus (1498-1553), and many others in Italy. In northern Europe should be mentioned Gulielmus Copus (1471-1532) and Günther of Andernach (1487-1584), better known as Guerius Andenascensis, both for a time professors at Paris; and, among the greatest, Thomas Linacre (about 1460-1524; see LINACRE). A little later Janus Cornarius or Hagenbut (1500-1558) and Leonhard Fuchs (1501-1566) in Germany, and John Kaye of Caithness (1515-1583) in England, contributed. Of the Syriac, Chaldaean, and Arabic, the two former and the latter, writing in Greek, were certainly the most important. Janus Cornarius, from whom this is quoted, seems to have made the greatest advance in the science of botany, but afterwards abandoned the same science. These were not the only physicians who contributed to this work, but they were the most important. The date of the first translation of a work of Hippocrates is 1531, when Cornarius published a Greek-Latin version of his “Aphorisms.”

The triumph of Galen was not complete before the middle of the 16th century. It was probably most so, and earliest, in the schools of Italy and in those of England, where the London College of Physicians might be regarded as an offshoot of the Italian schools. Paris was the stronghold of conservatism, and Germany was stirred by the teachings of one who must be considered apart from all schools—Paracelsus. The nature of the struggle between the rival systems may be well illustrated by a formidable controversy about the rules for bleeding in acute diseases. This operation, according to the Arabian practice, was always performed on a vein at a distance from the organ affected. The Hippocratic and also Galenic rule, to let blood from, or near to, the diseased organ, was revived by Pierre Brissot (1470-1522), a professor in the university of Paris. His attempt at reform, which was taken to be, as in effect it was, a revolt against the authority of the Arabian masters, led to his expulsion from Paris, and the formal prohibition of the practice of bleeding. Upon this apparently trifling question arose a controversy which lasted many years, occupied several universities, and led to the interposition of personages no less important than the pope and the emperor, but which is thought to have largely contributed to the final downfall of the Arabian medicine.

Paracelsus and Chemical Medicine.—Contemporary with the school of medical humanists, but little influenced by them, lived in Germany a man of strange genius, of whose character and importance the traditions told that he was the most original and revolutionary of all medical writers. Nearly all the medical schools and traditions of the Middle Ages and of the Renaissance are opposed to the primitive philosophy of Paracelsus (c. 1490-1541), who was his revolutionary independence of thought, which was supported by his immense personal arrogance. Himself well trained in the learning and medical science of the day, he despised and trampled upon all traditional and authoritative teachings. He began his lectures at Basel by burning the books of Avicenna and others; he afterwards boasted of having read no books for ten years; he protested that his shoe-huckles were more learned than Galen and Avicenna. On the other hand, he spoke with respect of Hippocrates, and wrote a commentary on his Aphorisms. In this he sees a spirit very different from the enthusiasm of the humanists for a purer and nobler philosophy than the scholastic and Arabian versions of Greek thought. There is no record of Paracelsus’ knowledge of Greek, and as, at least in his student days, the most important works of Greek medicine were very imperfectly known, it is probable he had little first hand acquaintance with Galen or Hippocrates, while his breach with the humanists is the more conspicuous from his lecturing and writing chiefly in his native German.

Having thus made a clean sweep of nearly the whole of the old doctrine, Paracelsus put in its place a philosophy of his own, one founded, according to his German expositors, on the views of the Neoplatonists, of which a few disjointed specimens must here suffice. The human body was a “microcosm” which corresponded to the “macrocosm,” and contained in itself all parts of visible nature,—sun, moon, stars and the poles of heaven. To know the nature of man and how to deal with it, the physician should study, not anatomy, which Paracelsus utterly rejected, but all parts of external nature. Life was a perpetual germinative process controlled by the vital force. Certain medicines, according to the mystical conception of Paracelsus, were not natural but spiritual. Nature was sufficient for the cure of most diseases; art had only to interfere when the internal physician, the man himself, was tired or incapable. Some remedy had to be introduced which should be antagonistic, not to the disease in a physical sense, but to the spiritual seed of the disease. These remedies were arcana—a word corresponding partly to what we now call specific remedies, but implying a mysterious connexion between the remedy and the essence of the disease. Arcana were often shown to be such by their physical properties, not only by such as heat, cold, &c., but by fortuitous resemblances to certain parts of the body; thus arose the famous doctrine of “signatures,” or signs indicating the virtues and uses of natural objects, which was afterwards developed into great complexity. Great importance was also attached to chemically prepared remedies as containing the essence or spiritual quality of the material from which they were derived. The actual therapeutical resources of Paracelsus included a
large number of metallic preparations, in the introduction of some of which he did good service, and, among vegetable preparations, the tincture of opium, still known by the name he gave it, laudanum. In this doubtless he derived much advantage from his knowledge of chemistry, though the science was as yet not disentangled from the secret traditions of alchemy, and was often mixed up with imposture.

German historians of medicine attach great importance to the references made by the Paracelsians, and trace in his writings anticipations of many scientific truths of later times. That his personality was influential, and his intrepid originality of great value as an example in his own country, is undeniable. As a nation, however, he was more a German than a Frenchman. But his importance in the universal history of medicine we cannot estimate so highly. The chief immediate result we can trace is the introduction of general remedies by Paracelsus, the use of which became a kind of badge of the disciples of Paracelsus. The use of these remedies was not, however, necessarily connected with a belief in his system, which seems to have spread little beyond his own country. Of the followers of Paracelsus some became more mystical quacks and impostors. Others, of more learning and better repute, were distinguished from the regular physicians chiefly by their use of chemical remedies. In France the introduction of antimony gave rise to a bitter controversy which lasted into the 17th century, and led to the expulsion of some men of mark from the Paris faculty. In England "chemical medicine" is first heard of, in like manner condemned and was assailed by the College of Physicians and the Society of Apothecaries. But it should be remembered that all the chemical physicians did not call Paracelsus master. The most notorious of that school in England, William Cullen (1550-1623), who made a most elaborate and extended use of Paracelsian lines of the art, but relies upon Arnold de Villanova and Raimon Lull. From this time, however, it is always possible to trace a school of chemical practitioners, who, though condemned by the orthodox Galenists, held their ground, till in the 17th century, a successor of Paracelsus arose in the celebrated J. B. Van Helmont.

Consequences of the Revival of Ancient Medicine.—The revival of Galenic and Hippocratic medicine, though ultimately it conferred the greatest benefits on medical sciences, did not immediately produce any important or salutary reform in practical medicine. The standard of excellence in the ancient writers was indeed far above the level of the 16th century; but the fatal habit of taking at second hand what should have been acquired by direct observation retarded progress more than the possession of better models assisted it, so that the fundamental faults of medieval science remained uncorrected.

Nevertheless some progress has to be recorded, even if not due directly to the study of ancient medicine. In the first place the 15th and 16th centuries were notable for the outbreak of certain epidemic diseases, which were unknown to the old physicians. Of these the chief was the "sweating sickness" or "English sweat," especially prevalent in, though not confined to, the country whence it is named. Among many descriptions of this disease, that by John Kaye or Calus, already referred to, was one of the best, and of great importance as showing that the works of Galen did not comprise all that could be known in medicine. The spread of syphilis, a disease equally unknown to the ancients, and the failure of Galen's remedies to cure it, had a similar effect.

In another direction the foundations of modern medicine were being laid during the 16th century,—namely, by the introduction of clinical instruction in hospitals. In this Italy, and especially the renowned school of Padua, took the first step, where Giovanni De Monte (Montanus), (1498-1552), already mentioned as a humanist, gave clinical lectures on the patients in the hospital St Francis, which may still be read with interest. Pupils flocked to him from all European countries; Germans are especially mentioned; a Polish student reported and published some of his lectures; and the Englishman Kaye was a zealous disciple, who does not, however, seem to have done anything towards transplanting this method of instruction to his own country. Inspections of the dead, to ascertain the nature of the disease, were made, though not without difficulty, and thus the modern period of the science of morbid anatomy was ushered in.

Medicine in the 17th Century.—The medicine of the early 17th century presents no features to distinguish it from that of the preceding century. The practice and theory of medicine were mainly founded upon Hippocrates and Galen, with ever-increasing additions from the chemical school. But the development of mathematical and physical science soon introduced a fundamental change in the habits of thought with respect to medical doctrine.

These discoveries not only weakened and destroyed the respect for authority in matters of science, but brought about a marked tendency to mechanical explanations of life and disease. When William Harvey by his discovery of the circulation furnished an explanation of many vital processes which was reconcilable with the ordinary laws of mechanics, the efforts of medical theorists were naturally directed to bringing all the departments of medicine under similar laws. It is often assumed that the writings and influence of Bacon did much towards introducing a more scientific method into medicine and physiology. But, without discussing the general philosophical position or historical importance of Bacon, it may safely be said that his direct influence can be little traced in medical writings of the first half of the 17th century. Harvey, as is well known, spoke slightly of the great chancellor, and it is not till the rapid development of physical science in England and Holland in the latter part of the century, that we find Baconian principles explicitly recognized.

The dominant factors in the 17th-century medicine were the discovery of the circulation by William Harvey (published in 1628), the mechanical philosophy of Descartes and the contemporary progress of physics, the teaching of Van Helmont on the chemical production of morbid processes, and finally, combined of all these, and inspiring them, the rise of the spirit of inquiry and innovation, which may be called the scientific movement. Before speaking in detail of these, we may note that by other influences quite independent of theories, important additions were made to practical medicine. The method of clinical instruction in hospitals, commenced by the Italians, was introduced into Holland, where it was greatly developed, especially at Leiden, in the hands of Francis de la Boe, called Sylvius (1641-1672). It is noteworthy that concurrently with the rise of clinical study the works of Hippocrates were more and more valued, while Galen began to sink into the background. At the same time the discovery of new diseases, unknown to the ancients, and the keener attention which the great epidemics of plague caused to be paid to those already known, led to more minute study of the natural history of disease. The most important disease hitherto undescribed was rickets, first made known by Arnold de Boot, a Friar who practised in Ireland, in 1649, and afterwards more fully in the celebrated work of Francis Glisson (1597-1677) in 1651. The plague was carefully studied by Isbrand de Dienerbroek, in his "Peste" (1646), and others. Nathaniel Hodges of London (1659-1688) in 1665 seems to have been the first who had the courage to make a post mortem inspection of a plague patient. Christopher Bennet (1617-1655) wrote an important work on consumption in 1654. During the same period many new remedies were introduced, the most important being cinchona-bark, brought to Spain in the year 1649. The progress of pharmacy was shown by the publication of Dispensatories or Pharmacobopica,—such as that of the Royal College of Physicians of London in 1675. This, like the earlier German works of the same kind (on which it was partly founded), contains both the traditional (Galenic) and the modern or chemical remedies.

Van Helmont.—The medicine of the 17th century was especially distinguished by the rise of systems; and we must first speak of an eccentric genius who endeavoured to construct a system for himself, as original and opposed to tradition as that of Paracelsus. J. B. van Helmont (1607-1678), a disciple of Galen, the father of modern medicine, who, after mastering all other branches of learning as then understood, devoted himself with enthusiasm to medicine and chemistry. By education and position a little out of the ordinary of his profession, he took up in medicine an independent attitude. Well acquainted with the doctrines of Galen, he rejected them as thoroughly as Paracelsus did, and borrowed from the latter some definite ideas as well as his revolutionary spirit. The archetype of Paracelsus...
appears again, but with still further complications—the whole body was controlled by the archæus insitus, and the organ of the soul and its various parts by the archæus insitus, which are subject to the central archæus. Many of the symptoms of diseases were caused by disarrangements of this archæus insitus, which was acted on by modifying the ideas of the same archæus. These and other notions cannot be here stated at sufficient length to be intelligible. It is enough to say that on this fantastic basis Helmont constructed a system which had no successors, for the self-evident, but peevish methods were mild and in many respects happy, and that he did service by applying newer chemical methods to the preparation of drugs. He thus had some share, though a share not generally recognized, in the abandonment of the so-called alchymy, which was to be spoken of. But his avowed followers formed a small and discredited sect, which, in England at least, can be clearly traced in the early part of the century.

Discovery of the Circulation of the Blood.—The influence of Harvey's discovery began to be felt before the middle of the century. Its merits were recognized by Descartes, among the first, nine years after its public principle which mainly distinguished it was not consequences in anatomy and physiology, but we must refer to the article Harvey. In respect of practical medicine, much less effect was at first noticeable. But this example, combined with the general principles, set many active and ingenious spirits to work to recon- struct the whole of medicine on a physiological or even a mechanical basis—to endeavour to form what we should now call physiological or mechanical systems. The result of this spirit to come from medicine, though it weakened the authority of the old dogma. The movement led rather to the formation of schools or systems of thought, which under various names lasted into the 18th century. The systems of Harvey and his followers did not last as systems, but that of Harvey, and especially the process of trituration; nutrition and secretion were shown to be dependent upon the tension of the vessels, and so forth. The developments of this system, and the physiological ideas, where they appear, seen in the light of modern science, as excellent though premature endeavours in a scientific direction. But the influence of these theories on practical medicine was not great. The more judicious of the mechanical or physical school restrained, as a judicious modern physician does, from too immediate an application of their principles to daily practice. Mechanical theories were apparently adapted to physiology, to the explanation of the phenomena of fever and the like, but had little or no influence on therapeutics. The most important men in this school after Borelli were Nicolaus Stensen (Steno), (1638–1686), Giorgio Baglivi (1669–1731), and, in the 18th century, John Hunter (1728–1793), and John Hunter (1733–1793), is also usually ranked with one of the most elaborate developments of the system was that of Archibald Pitscarr (1652–1713), a Scottish physician who became professor at Edinburgh. He was the founder of the first chemical school, and gave some remarkable, if not always correct, in the new views in physiology and chemistry with practical medicine. In some theoretical views, and in the use of certain remedies, the school owes much to Van Helmont and the physiologists of the 17th century. But the chemical school, as it was called, in the main an independent position. The founder of the first chemical school was Sylvius (1614–1672), who belonged to a French family settled in Holland, and was for fourteen years professor of medicine at Leiden, where he attracted students from all quarters of Europe. He made a resolute attempt to reconstruct medicine on the two bases of the doctrine of the circulation of the blood and the new views of chemistry. The circulation, which was supposed to be the basis of all life, was the chief object of his systems. Chemical disturbances of these processes, called activities, &c., were the cause of fevers and other diseases. Sometimes acid properties were attributed to the blood, sometimes to the secretion of the stomach, and produced corresponding disturbances. In nervous diseases disturbances of the vital "spirits" were most important. Still in some parts of his system Sylvius shows an acute understanding on anatomy and physiology. The system he employed was partly galenical, partly chemical. He was very moderate in the use of bleeding.

The doctrine of Sylvius became widely spread in Holland and Germany; less so in England. In England they were not generally accepted till adapted with some modifications by Thomas Willis the great anatomist (1621–1675), who is the chief English representative of the chemical school. Willis was as thoroughly a chemist as Sylvius. He regarded all bodies, organic and inorganic, as made up of phlegm, blood, and spirits, and everything was acted on by modifying the ideas of the same substances. There are other notions which cannot be here stated at sufficient length to be intelligible. It is enough to say that on this fantastic basis Helmont constructed a system which had no successors, for the self-evident, but peevish methods were mild and in many respects happy, and that he did service by applying newer chemical methods to the preparation of drugs. He thus had some share, though a share not generally recognized, in the abandonment of the so-called alchymy, which was to be spoken of. But his avowed followers formed a small and discredited sect, which, in England at least, can be clearly traced in the early part of the century.

The 18th Century.—The medicine of the 18th century is notable, like that of the latter part of the 17th, for the striving
HISTORY

MEDICINE

After complete theoretical systems. The influence of the iatro-physical school was by no means exhausted; and in England, especially through the indirect influence of Sir Isaac Newton's (1642-1727) great astronomical generalizations, it took on a mathematical aspect, and is sometimes known as iatro-mathematics. This phase is most clearly developed in Edinburgh: the Physicians of that city in the 18th century, who, though a determined opponent of metaphysical explanations, and of the chemical doctrines, gave to his own rude mechanical explanations of life and disease almost the dogmatic completeness of a theological system. His countryman and pupil, George Cheyne (1671-1743), who lived some years at Bath, published a new theory of fevers on the mechanical system, which had a great reputation. Their English contemporaries and successors, John Freind, William Cole, and Richard Mead, leaned also to mechanical explanations, but with a distrust of systematic theoretical completeness, which was perhaps partly a national characteristic, partly the result of the teaching of Sydenham and Locke. Freind (1675-1728) in his Emnennologia gave a mechanical explanation of the phenomena of menstruation. He is also one of the most distinguished writers on the history of medicine. Cole (1635-1716) (see above) published mechanical hypotheses concerning the causation of fevers which closely agree with those of the Italian iatro-mechanical school. More distinguished in his own day than any of these was Mead (1673-1754), one of the most accomplished and socially successful physicians of his time. He was the pupil of the equally popular and successful John Radcliffe (1651-1714), who had been driven from Sydenham a contempt for book-learning, and belonged to no school in medicine but the school of common sense. Radcliffe left, however, no work requiring mention in a history of medicine. Mead, a man of great learning and intellectual activity, was an ardent advocate of the mathematical doctrines. "It is very evident," he says, "that all other means of improving medicine have been found ineffectual, by the stand it was at for two thousand years, and that, since mathematicians have set themselves to the study of it, men already begin to talk so intelligently and comprehensively, not only that the greatest matters, that it is to be hoped that mathematical learning will be the distinguishing mark of a physician and a quack."

His Mechanical Account of Poisons, in the first edition (1702) gave an explanation of the effects of poisons, as acting only on the blood. Afterwards he modified his hypothesis, and referred the disturbances produced to the "nervous liquor," which he supposed to be a quantity of the "universal elastic matter" diffused through the universe, by which Newton explained the phenomena of light—i.e., what we afterwards called the "two universal principles." Mead's Mechanical Philosophy of the Sun and Moon over Human Bodies (1704), equally inspired by Newton's discoveries, was a premature attempt to assign the influence of atmospheric pressure and other cosmical causes in producing disease. His works contain, however, many original experiments, and excellent practical observations. James Keill (1673-1719) applied Newtonian and mechanical principles to the explanation of bodily functions with still greater accuracy and completeness; but his researches have more importance for physiology than for practical medicine.

Boerhaave.—None of these men founded a school—a result due in part to their intellectual character, in part to the absence in England of medical schools equivalent in position and importance to the universities of the Continent. An important academical position was, on the other hand, one of the reasons why a physician not very different in his way of thinking from the English physicians of the 18th century could be as able to exercise a domineering position in the medical world. Hermann Boerhaave (1668-1738) was emphatically a great teacher. He was for many years professor of medicine at Leiden, where he lectured five hours a day, and excelled in influence and reputation not only his own generation of doctors, but probably every subsequent teacher. The hospital of Leiden, though with only two beds, was available for teaching, because the demand of medical influence in Europe. Many of the English physicians of the 18th century studied there; Gerard Van Swieten (1700-1772), a pupil of Boerhaave, translated the latter's method of teaching to Vienna, and founded the noted Vienna school of medicine.

As the organizer, and almost the constructor, of the modern method of clinical instruction, the services of Boerhaave to the progress of medicine and in the immensity of the work were unparalleled. In his teaching, as in his practice, he avowedly followed the methods of the theoreticians and practitioners of the Netherlands, who, had they been acquainted with Sydenham and By the last named especially. His object was to make the anatomy of all the anatomical and physiological acquisitions of his age available to the student, by a complete and systematic, which he diligently studied, available for use in the practice of medicine. He thus differed from Sydenham, who took almost indiscriminately of medical knowledge from the ancient sources. He may be in some respects compared to Galen, but again differed from him in that he always abstained from attempting to reduce the knowledge to a uniform and coherent system. Boerhaave attached great importance to the physiological method in medicine, but rather treated them historically than quoted them as canonical authorities. It almost follows from the nature of the case that the great task of Boerhaave's life, a synthesis of ancient and modern medicine, and the work in which this is chiefly contained, his celebrated Institutions, could not have any great permanent value. Nearly the same thing is true even of the Aphorisms, in which, following the example of Hippocrates, he endeavoured to sum up the results of his long experience.

Hoffmann and Stahl.—We have now to speak of two writers in whose systematic tendency of the 18th century showed itself most clearly.

Friedrich Hoffmann (1660-1742), like Boerhaave, owed his influence, and perhaps partly his intellectual characteristics, to Leiden. In position as successor to his predecessor, who was the Rector of medicine in the university of Halle, he was only founded by the elector Frederick III. Here he became, as did his contemporary and rival Stahl, a popular and influential teacher, though their systems had not the same general influence. Hoffmann's system was "a system was apparently intended to reconcile the opposing "spiritual" and "materialistic," views of nature, and is thought to have been much influenced by the cosmology of Leibnitz. His medical theories rest upon a complete theory of the universe. 

Hoffmann's philosophy depended upon a universally diffused ether, which animals breathe in from the atmosphere, and which is contained in all parts of the body. If this ether is modified, the system is disturbed, and the body—one diseases being produced by excess of tone, or "spasm"; others by "atony," or want of tone. But it is impossible here to follow its further developments. Independently of his system, which has long ceased to exert any influence, Hoffmann made some contributions to practical medicine; and his great knowledge of chemistry enabled him to investigate the subject of mineral waters. He was equally skillful in surgery, but seems to have neglected the practice, which would be unpardonable in a modern physician of trafficking in secret remedies.

Anna Maria Stahl (1673-1754) was for more than twenty years professor of medicine at Halle, and thus a colleague of Hoffmann, whom he resembled in constructing a complete theoretical system, though their systems had little or nothing in common, on account of the difference in their intellectual conceptions. He substituted the theory of "animism"—attributing to the soul the functions of ordinary animal life in man, while the life of other creatures was left to mechanical laws. The symptoms of disease were explained as efforts of the soul to rid itself from morbid influences, the soul acting reasonably with respect to the end of self-preservation. The anima thus corresponds partly to the "nature" of Sydenham, while in other respects it resembles the archetypes of Van Helmont. Ananimism in its completeness met with little acceptance during the lifetime of its author, but influenced some of the iatromechanical school. Stahl was the author of the theory of "phlogiston," in chemistry, which in its day had great importance.

Haller and Morgani.—From the subtextes of rival systems it is a satisfaction to turn to two movements in the medicine of the 18th century which did not differ in principle from each other, except in the direction of system-making, opened up paths of investigation by which the systems were ultimately superseded. These are physiology in the modern sense, as developed from Haller, and pathological anatomy, as dating from Morgani.

Albrecht von Haller (1708-1777) was a man of even more encyclopaedic attainments than Boerhaave. He advanced chemistry, botany, zoology, anatomy, as well as medicine, as the result of a man of great authority, who, in order to occupy in endeavours to apply his scientific studies to practical medicine, thus continuing the work of his great teacher Boerhaave. But his work has been the exact opposite of that of his master, in the literature and bibliography of medicine than any one before or since. Haller occupied in the new university of Göttingen (founded 1737) a position corresponding to that of Boerhaave at Leiden, and in like manner influenced a very large circle of pupils.
The appreciation of his work in physiology belongs to the history of that science; we are only concerned here with its influence on medicine. Haller’s definition of irritability as a property of muscular tissue, incidentally he mentioned the deposition of phosphorus from seminal fluid, and the discovery of the hypothesis that the common bile duct was structured at the root of the prevailing hypothesis respecting animal activity. It was no longer necessary to suppose that a half-combined state of the blood was necessary to the completion of the system; but only the need of contriving other “systems” less open to objection; and thus the influence of Haller led directly to the theoretical subtleties of William Cullen and John Brown, and only indirectly to the brilliant and indirect ideas of P. F. Weikard. The name of Haller does not therefore occupy a very prominent place in the history of practical medicine.

The system of H. Battista Morgagni (1682–1771) had still preserved a permanent importance beyond that of all the contemporary theorists. In a series of letters, De sedibus et causis morborum per anatomen indagatis, published when he was in his eightieth year, he describes the appearances met with at the post-mortem examination as well as the symptoms during life in a number of cases of various diseases. It was not the first work of this kind. Swiss physician, Théophile Bonet (1620–1689) had published his Sepulchrum in 1679, and observations of post-mortem appearances had been made by Montanuas, P. Tulp, Raymond Vieussens, A. M. Valsalva, G. M. Lancedo, Haller and others ever since. The work of Morgagni was so absolutely coherent and comprehensive, described with such accuracy, or illustrated with equal anatomical and medical knowledge. Morgagni’s work at once made an epoch in the science. Morbid anatomy now became a recognised branch of medical literature, and the movement which started has lasted till our own day.

The contribution of Morgagni to medical science must be regarded as one of the most important achievements of the age; it had, in neglecting anatomy, neglected the most solid basis for studying the natural history of disease; though perhaps it was less from choice than because his practice, as he was not attached to a hospital, gave him no opportunities. But it is on the contrary the two methods—that of Sydenham and of Morgagni—that modern medicine rests; and it is through these that it has been able to make steady progress in its own field, independently of the advance of physiological sciences.

The method of Morgagni found many imitators, both in his own country and in others. In England the first important name in this field is that of the first writer of a systematic work in any language on morbid anatomy, William Baillie (1761–1823), a nephew of John and William Hunter, who published his treatise in 1795.

Cullen and Brown.—It remains to speak of two systematic writers on medicine in the 18th century, whose great reputation prevents them from being passed over, though their real contributions to medicine were not of the same order. William Cullen (1710–1790) was a most eminent and popular professor of medicine at Edinburgh. The same physiological influences as surrounded the Dutch and German founders of systems were at the same time concentrated in the person of Cullen, a founder of a comprehensive system of medicine. Cullen’s system was largely based on the new physiological doctrine of irritability, but is especially noticeable for the importance attached to nervous action. Thus even gut was regarded as a “nervous.” These pathological principles of Cullen are contained in his First Lines of the Practice of Physic, an extremely popular book, often reprinted and translated. More importance is to be attached to his Anatomy or Classification of Diseases. The attempt to classify diseases on a natural-history plan was not new, having been commenced by Sauvages and others, and is perhaps not a task of the highest importance. Cullen drew out a classification of great complexity, the chief part of which is now forgotten, but several of his main divisions are still preserved.

It is difficult for us to form a clear estimate of the importance of the later works of English medicine; John Brown (1735–1788)—for, though in England he has been but little regarded, the wide though short-lived popularity of his system on the Continent shows that it must have contained some elements of brilliancy, if not originality. His theory of medicine professed to explain the processes of life and disease, and the methods of cure, upon one simple principle—that of the property of ‘excitability,’ in virtue of which the ‘animal’ nervous system was divided into the ‘irritable’ and the ‘sedentary’ portion, and the excitability of functions of the system itself, call forth the vital phenomena “sense, motion, mental function and passion. All exciting powers are supposed to produce these phenomena, and disease and debility or invalidism caused by being due to a deficiency in the degree of stimulus; so that the final conclusion is that the whole phenomena of life, health as well as disease, consist in stimulus and nothing else. Brown regarded irritability as a universal property, just as atrophia requiriuit stimulating treatment, the former the reverse; but his practical conclusion was that 97% of all diseases required a ‘stimulating’ treatment. In this he claimed to have made the most salutary reform because all physicians from Hippocrates had treated diseases by depilation and debilitating measures with the object of curing by elimination from the body of a poison or a peculiar fluid of the Brunnonian system; and it is difficult now to understand why it attracted so much attention in its day. To us at the present time it seems merely a dialectical and physiological system, which has been long out of fashion. But Brown may be said to have been the first advocate of the modern stimulating or feeding treatment of fevers. He advocated the use of ‘animal stimulants’, because he believed that to declare certain symptoms—such as convulsions and delirium, which were then commonly held always to indicate inflammation—were often really signs of weakness.

The doctrines of Johann Baptiste Vieussens (1753–1844), having been originally written in Latin, the Brunnonian form one of the strangest chapters in the history of medicine. In Scotland, Brown so far won the sympathy of the students that riotous conflicts took place between his partisans and opponents. In England his system took little root. In Italy, on the other hand, it received enthusiastic support, and, naturally, a corresponding degree of opposition. Though the system adherent to Brown’s system was too marked for any theoretical system to have more than a passing influence. In France, however, the influence of Brown’s theories was very clearly seen in the writings of François J. V. Broussais, who though not rigourous, his conclusions were partly based upon anatomical investigation, and resembled them in his attempt to unite theory and practice in one system. The influence of the system has been far more marked in other medical schools and in Germany was as great as in Edinburgh or in Italy, and led to serious riots in the university of Göttingen. In America, the practice of medicine was inspired by Brown’s system, which was adopted as the object at his death. In England it was somewhat different. Intellectual activity was not wanting, but the great achievements of the 18th century in philosophy and the moral sciences had fostered a love of abstract speculation; and some sort of cosmical system was thought indispensable in every departure of special science. Hence another generation had to pass away before England found herself on the level, in scientific investigation, of the other countries of Europe.

Before the theoretical tendency of the 18th century was quite exhausted, it displayed itself in a system which, though in some respects isolated in the history of medicine, stands nearest to that which the studying of diseases has led to. S. C. F. Hahnemann (1753–1844) was in conception as revolutionary a reformer of medicine as Paracelsus. He professed to base medicine entirely on a knowledge of symptoms, excluding all investigation of the causes of symptoms. While thus rejecting all the lessons of morbid anatomy and pathology, he put forward views respecting the causes of disease which hardly bear to be seriously considered. He regarded acupuncture as a disease, scorbutica (the itch), syphilis or syphosis (a skin disease), or else were maladies produced by medicines. Seven-eighths of all chronic diseases are produced by itch driven inward. It is fair to say that all attempts to analyse the physical agent and its relation in treatment of disease Hahnemann rejected entirely the notion of a vis medicatrix naturae, and was guided by his well-known principle that disease is a process in which the whole development of a disease is that which it produces. The modern system of medicine is as much indebted to Paracelsus, though less so, as to the Hippocratic school, for there are many points of resemblance in the views of both.
"similis similibus curantur," which he explained as depending on the law that in order to get rid of a disease some remedy must be given that is similar to it in order to be active for it. This is an action not in the similar, but weaker. The original malady being thus got rid of, the vital force would easily be able to cope with and extinguish the slight disorder which the Brownian medicine caused. Something very similar was held by Brown, who taught that "indirect debility," was to be cured by a lesser degree of the same stimulus as had caused the original disturbance. Generally, however, Hahnnemann's view of the law of similarity was that of Brown. He could not see in the same plane. In order to select remedies which should fulfil the indication of producing symptoms like those of the disease, Hahnnemann made many observations of the action of drugs on healthy persons.

He did not originate this line of research, for it had been pursued, if not originated, by Haller, and cultivated systematically by Tommasini, an Italian "contra-stimulator"; but he carried it out with much elaboration. His results, nevertheless, were vitiated by being obtained in the interest of a theory, and by singular want of discrimination. In his second period he developed the theory of "potentiality" or dynamization—namely, that medicines gained in strength by being diluted, if the dilution was accompanied by shaking or pounding, which was supposed to "potentize" or increase the potency of the medicine. On this principle Hahnnemann ordered his original tinctures to be reduced in strength to one-fiftieth; these first dilutions again to one-fiftieth; and so on, even till the thirtieth dilution, which he himself used by preference, and to which he ascribed the highest "potentiality." From a theoretical point of view, however, this is one of the most absurd systems, proceeding to universality, which modern medicine neither accepts nor finds it worth while to controvert. In the treatment of disease his practical innovations came at a fortunate time, when the system of the Bulletist system had only partially been superseded by the equally injurious opposite extreme of Brown's stimulating treatment.

Hahnnemann's use of mild and often quite inert remedies contrasted favorably with these. He taught that different agents are able to exert different powers, but that the greatest good can only be obtained upon simplicity in prescribing, when it was the custom to give a number of drugs, often heterogeneous and inconsistent, in the same prescription. But these indirect benefits were quite independent of the truth or falsity of his theoretical system.

Positive Progress in the 18th Century.—In looking back on the repeated attempts in the 18th century to construct a universal system of medicine, it is impossible not to regret the waste of brilliant gifts and profound acquirements which they involved. It was fortunate, however, that the accumulation of positive knowledge in medicine did not cease. While Germany and Scotland, as the chief homes of abstract speculation, gave birth to most of the theories, progress in objective science was most marked in other countries—in Italy first, and afterwards in England and France. We must note our steps a little to enumerate several distinguished names which, from the nature of the case, hardly admit of classification.

In Italy the tradition of the great anatomists and physiologists of the 17th century produced a series of accurate observers and experimenters among the younger. Maria Valsalva (1666-1733), still better known as an anatomist; Giovanni Maria Lancisi (1654-1726), also an anatomist, the author of a classical work on the diseases of the heart and aneurisms; and Ippolito Francesco Albertini (1662-1738), whose researches on the same class of diseases were no less important.

In France, Jean Baptiste Séanc (1693-1770) wrote also an important work on the affections of the heart. Sauvages, otherwise P. B. de Lacroix (1706-1767), gave, under the title "Nouvelles méthodes," a natural-history classification of diseases; and Baron de Jussieu (1748-1836) the "Nouveau système" of the known general diseases. But the state of medicine in that country till the end of the 18th century was unsatisfactory as compared with some other parts of Europe.

In England the brilliancy of the early part of the century in practical medicine was hardly maintained to the end, and presented, indeed, a certain contrast with the remarkable and unflagging progress of surgery in the same period. The roll of the College of Physicians does not furnish many distinguished names. Among these should be mentioned John Fothergill (1710-1779), who distinguished himself in the treatment of the now called diphtheria, and the form of neuralgia popularly known as tic douloureux. A physician of Plymouth, John Huxham (1664-1768), made researches on epidemic fevers, in the spirit of Sydenham and Hippocrates, which are of the highest importance. William Heberden (1710-1801), a London physician, called by Samuel Johnson "ulimus Romanorum, " the last of our learned physicians," left a rich legacy of practical observations in the "Comenarum" published after his death.

More important in their results than any of these works were the discoveries of Edward Jenner (c. 1749, respecting the prevention of small-pox by vaccination, in which he superseded the partially useful but dangerous practice of inoculation, which had been introduced into England in 1721. The history of this discovery need not be told here, but it may be pointed out that, apart from its practical importance, it has had great influence on the scientific study of infectious diseases. The name of John Pringle (1707-1782) should also be mentioned as one of the first to study epidemics of fevers occurring in prisons and camps. His work, entitled "Observations on the Diseases of an Army," was translated into many European languages and became the standard authority on the subject.

In Germany the only important school of practical medicine was that of Vienna, as revived by Gerard van Swieten (1700-1772), a pupil of Boerhaave, under the patronage of Maria Theresa. Van Swieten's commentaries on the aphorisms of Boerhaave are thought more valuable than the original text. Other eminent names of the same school are Antion de Haën (1704-1776), Anton Störck (1731-1803), Maximilian Stoll (1742-1788), and John Peter Frank (1745-1821), father of Joseph Frank, before mentioned as having been for the Brownian system, and like his son carried away for a time by the new views. The old "Vienna School," was not distinguished for any notable discoveries, but for success in clinical teaching, and for its sound method of studying the actual facts of disease during life and after death, which largely contributed to the establishment of the "positive medicine" of the 19th century.

One novelty, however, of the first importance is due to a Vienna physician of the period, Leopold Auenbrugger (1722-1800), the inventor of the method of recognizing diseases of the chest by percussion. Auenbrugger's method was that of direct percussion with the tips of the fingers, not that which is now used, of mediate percussion with the intervention of a finger or pessimeter; but the results of his method were the same and its value nearly as great. Auenbrugger's great work, the "Inventum novum," was published in 1761. The new practice was received at first with contempt and even ridicule, and afterwards by Stoll and Peter Frank with only grudging approval. It did not receive due recognition till 1808, when J. N. Corvisart translated the "Inventum novum" into French, and Auenbrugger's method rapidly attained a European reputation. Surprised, but not eclipsed, by the still more important art of auscultation introduced by R. T. H. Laennec, it is hardly too much to say that this simple and purely mechanical invention has had more influence on the development of modern medicine than all the "systems" evolved by the most brilliant intellects of the 18th century.

Rise of the Positive School in France.—The reform of medicine in France must be dated from the great intellectual awakening caused by the Revolution, but more definitely starts with the researches in anatomy and physiology of Marie François Xavier Bichat (1771-1802), generally regarded as the founder of histology, especially of the Anatomie générale, cannot be estimated here; we can only point out their value as supplying a new basis for pathology or the science of disease. Among the most ardent of his followers was François Joseph Victor Broussais (1772-1838), whose theoretical views, partly founded on those of Brown and partly on the so-called vitalist school of Théophile Bordeu (1772-1776) and Paul Joseph Barthez (1734-1806), differed from these essentially in being avowedly based on anatomical observations. Broussais's chief aim was to find an anatomical basis for all diseases, but is especially known for his attempts to explain all fevers as a consequence of irritation or inflammation of the intestinal canal (gastro-enteritis). A number of other maladies, especially general diseases and those commonly regarded as nervous, were attributed to the same cause. It would be impossible now to trace
the steps which led to this wild and long since exploded theory. It led, among other consequences, to an enormous misuse of bleeding. Leeches were his favourite instruments, and so much so that he is said to have used 100,000 in his own hospital wards during one year. He was equalled if not surpassed in this excess by his follower Jean Bouillaud (1796-1881), known for his important work on heart diseases. Broussais's system, to which he gave the name of "Médecine physiologique," did much indirect good, in fixing attention upon morbid changes in the organs, and thus led to the rise of the strongly opposed anatomical and pathological school of Corvisart, Laennec and Bayle.

Jean Nicolas Corvisart (1735-1801) has already been mentioned as the precursor for France of Auenbruger's work on percussion. He introduced some improvements in the method, but the only real advance was the introduction of mediate percussion by Pierre Adolph Pierry (1794-1797) in 1828. The discovery had, however, yet to be completed by that of auscultation, or listening to sounds produced in the chest by breathing, the movements of the heart, &c. The combination of these methods constitutes what is now known as the diastat. René-Hyacinthe Laennec (1781-1826) was the inventor of this most important perhaps of all methods of medical research. Except for some trifling notices of sounds heard in certain diseases, the method with which we are concerned was definitely expounded in an almost complete form in his work De l'auscultation médicale, published in 1819. Laennec attached undue importance to the use of the stethoscope, and laid too much weight on specific signs of specific diseases. Yet his method introduced a feature which was the result of his discovery was an entire revolution in the knowledge of diseases of the chest; but it would be a mistake to give the credit of the discovery to Laennec alone. Yet an important discovery, the simultaneous study of the condition of the diseased organs as seen after death. Without the latter, it is difficult to see how the information conveyed by sounds could ever have been verified. This increase of knowledge is therefore due, not to auscultation alone, but to auscultation combined with morbid anatomy. In the case of Laennec himself this qualification takes nothing from his fame, for he studied so minutely the relations of post-mortem appearances to symptoms, and laid down so clearly the general principles of the anatomy of morbid anatomy would have made him famous. The pathologico-anatomical method was also followed with great zeal and success by Gaspard Laurent Bayle (1774-1816), whose teachings on tubercle, and the changes of the lungs and other organs in consumption, are the foundation of most that has been done since his time. It was of course antecedent to the discovery of auscultation. Starting from these men arose a school of physicians who endeavoured to give to the study of symptoms the same precision as belonged to anatomical observations, and by the combination of the two methods to make medicine scientific. Among these were Auguste François Chomel (1788-1858), Pierre Alexandre Louis (1787-1872), Jean Cruveilhier (1791-1874) and Gabriel Andral (1797-1876). Louis, by his researches on pulmo- nary Perfusion and typhoid fever, and the chief merit of refuting the doctrines of Broussais. In another respect also he aided in establishing an exact science of medicine by the introduction of the numerical or statistical method. By this method only can the fallacies which are attendant on drawing conclusions from isolated cases be avoided; and thus the chief objection which has been made to regarding medicine as an inductive science has been removed. Louis's method was improved and systematized by Louis Denis Jules Gavarret (1800-1890)—and its utility is now universally recognized. During this brilliant period of French medicine the superiority of the school of Paris could hardly be contested. The names mentioned, the chief merit of Paul Pierre (1771-1862), Louis Léon Rostan (1750-1866), Jean Louis D'Alibert (1766-1837), Pierre François Oliver Rayer (1793-1867) and Armand Trousseau (1801-1866), the eloquent and popular teacher.

**English Medicine from 1800 to 1830.**—The progress of medicine in England during this period displays the same characteristics as at other times, viz. a gradual and uninterrupted development, without startling changes such as are caused by the sudden rise and fall of fashion. Here we have the doctrines of English birth; Erasmus Darwin (1731-1802), the grandfather of the great Charles Darwin, alone makes an exception. In his Zoonomia (1794) he expounded a theory of life and disease which had some resemblance to that of Brown, though arrived at (he says) by a different chain of reasoning.

Darwin's work shows, however, the tendency to connect medicine with physical science, which was an immediate consequence of the scientific discoveries of the end of the 18th century, as Priestley and Cavendish in England exercised the same influence as Lavoisier in France. The English school of medicine was also profoundly stirred by the teachings of the two brothers William and John Hunter, especially the latter—who must therefore be briefly mentioned, though their own researches were chiefly concerned with subjects lying under the limits of this sketch. William Hunter (1718-1783) was known in London as a brilliant teacher of anatomy and successful obstetric physician; his younger brother and pupil, John Hunter (1728-1793), was also the teacher of anatomy, and practised as a surgeon. His immense contribution to anatomy and pathology cannot be estimated less, but his services in stimulating research and training investigators belong to the history of general medicine. They are sufficiently evidenced by the fact that Edward Jenner and Matthew Baillie were his pupils.

The same scientific bent is seen in the greater attention paid to morbid anatomy (which dates from Baillie) and the more scientific method of studying diseases. An instance of the latter is the work of Robert Willan (1757-1812) on diseases of the skin—a department of medicine in which abstract and clinical views had been generally injurious. For instance, by following the natural-history method of Sydenham, at once put the study on a sound basis; and his work has been the starting-point of the most important modern researches. About the same time William Charles Wells (1757-1817), a scientific investigator of remarkable power, and the author of a celebrated essay on cew, published observations on alterations in the urine, which, though little noticed at the time, were of great value as assisting in the important discovery made some years afterwards by Richard Bright.

These observations could not be mentioned here, belong to the period when English medicine was still little influenced by the French school. Shortly after 1815, however, when the continent of Europe was again open to English travelers, many English doctors studied in Paris, and the discoveries of their great French contemporaries began to be known. The method of auscultation was soon introduced into England by pupils of Laennec. John Forbes (1787-1861) in 1824, and William Stokes (1804-1878) of Dublin in 1825, published writings on the use of the stethoscope. Forbes also translated the works of Laennec and Auenbrugger, and an entire revolution was soon effected in the knowledge of the diseases of the chest. James Hope (1801-1841) and Peter Mere Latham (1789-1875) further developed this subject, and the former was also known for his researches in morbid anatomy. The combination of clinical and anatomical research led, as in the hands of the great French physicians, to important discoveries by English investigators. The discovery by Richard Bright (1789-1858) of the disease of the kidneys known by his name proved to be one of the most momentous of the century. It was published in Reports of Medical Cases 1827-1831. Thomas Addison (1793-1860) takes, somewhat later, a scarcely inferior place. The remarkable physiological discoveries of Sir Charles Bell (1774-1842) and Marshall Hall (1790-1857) for the first time rendered possible the discrimination of diseases of the spinal cord. Several of these physicians were also eminent for their clinical teaching—an art in which Englishmen had up till then been greatly deficient.

Although many names of scarcely less note might be mentioned among the London physicians of the early part of the century, we must pass them over to consider the progress of medicine in Scotland during this period. In England the admirable teaching of Cullen had raised the medical faculty to a height of prosperity of which his successor, James Gregory (1758-1821), was not unworthy. His pupil, Philip Miller (1761-1839), was received into the Royal College of Physicians, where he was so well known. These great teachers maintained in the northern university a continuous tradition of successful teaching, which the difference in academic and other circumstances rendered hardly possible in London. Nor was the northern school wanting in special investigators, such as John Abercrombie (1780-1844), known for his work on diseases of the bone and spinal cord, published in 1828, and others. Turning to Ireland, it should be said that the Dublin school in this period produced two physicians of the greatest distinction. Robert James Graves (1796-1853) was a most eminent clinical teacher and observer, whose lectures are regarded as the
model of clinical teaching, and indeed served as such to the most popular teacher of the Paris school in the middle of this century, Troussseau. William Stokes (1804-1878) was especially known for his work on diseases of the chest and of the heart, and for his clinical teaching.

German Medicine from 1800 to 1840.—Of the other countries of Europe, it is now only necessary to mention Germany. Here the chief home of positive medicine was still for a long time Vienna, where the new Vienna school of medicine, continued and surpassed the glory of the H. dichotomies in the eighteenth century. Here, the modern methods of clinical teaching, and in some respects corrected, the art of assecdutation as left by Laennec. Karl Rokitansky (1804-1878), by his colossal labours, placed the science of morbid anatomy on a permanent basis, and enriched it by numerous discoveries of detail. Most of the ardent cultivators of this science in Germany in the next generation were his pupils. In the other German schools, though some great names might be found, as Moritz Heinrich Romberg (1795-1873), the founder of the modern era in the study of nervous diseases, the general spirit was scholastic and the result barren till the teaching of one man, whose the modern German Physicians generally regard as the reincarnation of a great mind, hacen from the year 1839-1859). Schölen's positive contributions to medical science were not large; but he made in 1839 one discovery, apparently small, but in reality most suggestive, namely, that the contagious disease of the head, called favus, is produced by the growth in the hair of a parasitic fungus. In this may be found the germ of the startling modern discoveries in parasitic diseases. The method of the so-called "natural history school"; but his real merit was that of the founder or introducer of a method. In the words of H. Hiser: "Schölen has the incontestable merit of having been the first to establish in Germany the exact method of the French and the English, and to impregnate this method with the vivifying spirit of German research."

(J. F. P.)

Modern Progress.—In recent times the positive bent of modern knowledge and methods in other spheres of science and thought, and especially in biology, has influenced medicine profoundly. Minute accuracy of observation was inculcated by the labour of the great German physiologists, anatomists of the 17th century; and, for modern times, experimental physiology was instituted by Harvey, anatomy having done little to interpret life in its dynamic aspects. For medicine in England Harvey did what William Gilbert did for physics and Robert Boyle for chemistry; he insisted upon direct interrogation of natural processes, and thereby annihilated the ascendancy of mere authority, which, while nations were in the making, was an essential principle in the welding together of heterogeneous and turbulent peoples. The degradation of medicine between Galen and Harvey, if in part it consisted in the blind following of the authority of the former physician, was primarily due to other causes; and its new development was not due to the discovery of the experimental method alone: social and political causes also are concerned in the advance even of the exact sciences. Among such contributory causes is the more familiar intercourse of settled nations which we enjoy in our own day; the ideas of one nation rapidly permeate neighbouring nations, and by the means of printed books penetrate into remotest provinces and into distant lands. Hence the description of the advance of medicine in western Europe and America may for the latest stage be taken as the whole, with the exception of the 17th century by nation, which in the history of earlier times was necessary. Italy lost the leading place she had taken in the new development of science. The several influences of modern Germany, France and America became of the first importance to English medicine; but these tides, instead of pursuing their courses as independent streams, have become confluent. The work of Theodor Schwann (1810-1882), Johannes Müller (1801-1875), Rudolph Virchow and Karl Ludwig (1816-1891) in Germany, of R. T. H. Laennec and Claude Bernard in France, was accepted in England, as that of Matthew Baillie, Charles Bell, Bright, Graves and others of the British school, quickly made itself felt abroad.

The character of modern medicine cannot be summed in a word, as, with more or less aptness, that of some previous periods may be. Modern medicine, like modern science, is as boldly speculative as it has been in any age, and yet it is as observant as in any naturalistic period; its success lies in the addition to these qualities of the method of verification; the fault of previous times being not the activity of the speculative faculty, without which no science can be fertile, but the lack of methodical reference of all and sundry propositions, and parts of propositions, to the test of experiment. In no department is the experimental method more continually justified than in that of the natural history of disease, which at first sight would seem to have a certain independence of it and a somewhat exclusive value of its own. Hippocrates had no opportunity of verification by necropsy, and Sydenham ignored pathology; yet the clinical features of many but recently described diseases, though, for example, as that named after Graves, and myxoeodema, both associated with perversions of the thyroid gland, lay as open to the eye of physicians in the past as to our own. Again, to the naturalist the symptoms of tabes dorsalis were distinctive enough, had he noted them. No aid to the trained eye was necessary for such observations, and for many other such; yet, if we take Sir Thomas Watson (1792-1882) as a modern Sydenham, we may find in his lectures no suspicion that there may be a palsy of muscular co-ordination apart from deprivation of strength. Indeed, it does not seem to have occurred to any other than to the peculiar strength in the various kinds of paraliga. Thus it was, partly because the habit of acceptance of authority, vanishing far from extinguished, dictated to the clinical observer what he should see; partly because the eye of the clinical observer lacked that special training which the habit and influence of experimental verification alone can give, that physicians, even acute and practised physicians, failed to see many and many a symptomatic series which went through its evolutions conspicuously enough, and needed for its appreciation no unknown aids or methods of research, nor any further advances of patho-

...
disease in its static aspects only, and also for the most part in the particular aspect of final dissolution; and it became manifest as pathology and clinical medicine became more and more thoroughly integrated, that the processes which initiate and are concerned in this dissolution were not revealed by the scalpel.

Again, the physician as naturalist, though stimulated by the pathologist to delineate disease in its fuller manifestations, yet was hampered in a measure by the didactic method of constructing "types" which should command the attention of the disciple and rivet themselves on his memory; thus too often those incipient and transitory phases which initiate the paths of dissolution were missed. Not only so, but the physician, thus fascinated by "types," and impressed by the silent monuments of the pathological museum, was led to localize disease too much, to isolate the acts of nature, and to forget not only the continuity of the phases which lead up to the exemplary forms, or link them together, but to forget also that even between the types themselves relations of affinity must exist—and these oftentimes none the less intimate for apparent diversities of form, for types of widely different form may be, and indeed often are, more closely allied than types which have more superficial resemblance—and to forget, moreover, how largely negative is the process of abstraction by which types are imagined. Upon this too static a view, both of clinical type and of post-mortem-room pathology, came a despairing spirit, almost of fatalism, which in the contemplation of organic ruins lost the hope of cure of organic diseases. So prognosis became pessimistic, and the therapeuticists of the latter men negative, until fresh hopes arose of stemming the tides of evil at their earliest flow.

Such was medicine, statically ordered in pathology, statically ordered in its clinical concepts, when, on the 24th of November 1859, the Origin of Species was published. It is an exaggeration to say that this epoch-making work brought to birth a world of conceptions as new as the work of Copernicus. For the natural philosopher the whole point of view of things was changed; in biology not only had the anthropocentric point of view been banished, but the ancient concept of perpetual flux was brought home to ordinary men, and entered for good into the framework of thought. The study of comparative pathology, yet in an inchoate stage, and of embryology, illuminated and enlarged biological conceptions, both normal and abnormal; and the once real subdivisions in corpore disappeared forever—at any rate from physiology and medicine. Before Darwin—if the name of Darwin may be used to signify the transformation of thought of which he was the chief artist—natural objects were regarded, not in medicine and pathology only, as a set of hidebound events; and natural operations as moving in fixed grooves, after a fashion which it is now difficult for us to realize. With the melting of the ice the more daring spirits dashed into the new current with such ardour that for them all traditions, all institutions, were thrown into hotchpot; even elderly and sober physicians took enough of the infection to liberate their minds, and, in the field of the several diseases and in that of post-mortem pathology, the hollowness of classification by superficial resemblance, the transitoriness of forms, and the flow of processes, broke upon the view. Thus it came about not only that classifications of disease based on superficial likeness—such as jaundice, dropsey, inflammation—were broken up, and their parts redistributed, but also that even more set diseases began to lose their setlements, and were recognized as terms of series, as transitory or culminating phases of perturbation which transcended to their origins, and in their earlier stages perhaps withstood.

The doctrine of heredity in disease thus took a larger aspect; the view of morbid series was no longer bounded even by the life of the individual; and the propagation of taints, and of morbid varieties of man, from generation to generation proved to be no mere repetition of fixed features but, even more frequently, to be modes of development or of dissolution betraying themselves often in widely dissimilar forms, in series often extending over many lives, the terms of which at first sight had seemed wholly disparate. Thus, for example, as generations succeed one another, nervous disorders appear in various guises; epilepsy, megrim, insanity, asthma, hystera, morrhæa; a motley array at first sight, seemed to reveal themselves as terms of a morbid series; not only so, but certain disorders of other systems also might be members of the series, such as certain diseases of the skin, and even peculiar susceptibilities or immunities in respect of infections from without. On the other hand, not a few disorders proved to be alien to classes to which narrower views of causation had referred them; of such are tubers doraus, nevrits, infantile palsy or tetanus, now removed from the category of primary nervous diseases and placed in one or other of the class of infectious diseases; or, conversely, certain forms of disease of the joints are now regarded with some confidence as members of more than one series of diseases chiefly manifest in the nervous system. In the effects of simpler poisons the recognition of unity in diversity, as in the affiliation of a peripheral neuritis to arsenic, illustrated more definitely this serial or etiological method of classifying diseases. On the other hand, inheritance was dismissed, or survived only as a "susceptibility," in the cases of tubercle, leprosy and some other maladies now recognized as infectious; while in others, as in syphilis, it was the germ of the disease which infected a man from parent to offspring. These new conceptions of the multiplicity in unity of disease, and of the fluidity and continuity of morbid processes, might have led to vagueness and over-boldness in speculation and reconstruction, had not the experimental method been at hand with clues and tests for the several series. Of this method the rise and wonderful extension of the science of bacteriology also furnished no inconsiderable part.

In the disease of the scalp called favus, Schönlein had discovered a minute mycelial fungus; a remarkable discovery, for it was the first concrete step in the attribution of diseases to the microorganisms of the organism; and Schönlein thus did something to introduce new and positive conceptions and exacter methods into Germany; but unfortunately his own mind retained the abstract habit of his country, and his abilities were dissipated in the mere speculations of Schelling. Similarly Karl Hoffmann of Würzburg wasted his appreciations of the newer schools of developmental biology in fanciful notions of human diseases as reversions to normal stages of lower animals; scrofula being for him a reversion to the insect, ticks to the mollusc, epilepsy to the oscillaria, and so forth. Molecular physiology, an experimental science, has thrown a staunch vitalism. Fortunately Germany, which at the beginning of the century was delivered over to Brownism and vitalism and was deaf to Bichat, was rescued from this sort of barrenness by the brilliant experimental work of Claude Bernard and Pasteur in France—work which, as regards the attenuated virus, was a development of that of Edward Jenner, and indeed of Schwann, Robert Koch worthily following Pasteur with his work on the bacillus of anthrax and with his discovery of that of tuberculosi; and by the cellular doctrine and abundant labours in pathology of Virchow. Ludwig Bürger then discovered the toxins of certain infections; and Emil A. von Behring completed the sphere of the new study by his discovery of the antitoxins of diphtheria and tetanus. In practical medicine the subsequent results of Behring and his followers have in diphtheria attained a signal therapeutic success. If the striking conceptions of Paul Ehrlich and Emil Fischer continue to prove as fertile in inspiring and directing research as at present they seem to be, another wide sphere of conceptions will be opened out, not in bacteriology only, but also in biological chemistry and in molecular physics. Again, besides giving us the clue to the nature of many diseases and to the continuity of many morbid series, by bacteriology certain diseases, such as actinomycosis, have been recognized for the first time.

As the prevalence of the conceptions signified and inspired by the word "phlogiston" kept alive ontological notions of disease, so the dissipation of vitalistic conceptions in the field of physics prepared men's minds in pathology for the new
views opened by the discoveries of Pasteur on the side of bacteriology, and of J. F. Cohnheim (1839-1884) and of Ilija Mečtchikoff on the dynamical side of histology. Of the older ontological notions of disease the strongest were those of the essence of fever and of the essence of inflammation. Broussais had done much to destroy the notion of fever as an entity, but by extravagances in other directions he had discredited the value of his main propositions. Yet, although, as Andral and other French physicians of the 19th century who extended their thoughts to the etiology of disease, took their origin from some local inflammation, it was true and most useful to insist, as Broussais vehemently insisted, that "fever" is no substance, but a generalization drawn from symptoms common to many and various diseases springing from many various and often local causes; from causes agreeing perhaps only in the factor of elevation of the temperature of the body. To the establishment of this new conception the improvement and general use of the *clinical thermometer* gave invaluable advantages. This instrument, now indispensable in our daily work at the bedside, had indeed long been known both to physiologists (Haller) and to clinicians. In the 18th century A. de Haen, and, in the United Kingdom, George Cleghorn (1716-1789) of Dublin and James Currie (1756-1809), carried on the use of the thermometer in fevers; and on the continent of Europe in later years F. G. F. von Bürrenprung (1822-1865) and Ludwig Traube (1818-1876) did the same service; but it is to the work of Karl August Wunderlich (1815-1877) that we owe the establishment of this means of precision as a method of regular observation both in pathology and in clinical medicine. By his almost exhaustive comparison of febrile movements as symptomatic phenomena, Wunderlich dealt the last blow to the expiring doctrine of the "entity" of "fever"; while on the clinical side Bretonneau and Louis, in 1862-1872, by their careful clinical and pathological studies of forms of fever, relieved the new doctrine of the extravagances of Broussais, and prepared the way for the important distinction of enteric from typhus fever by A. P. Stewart (1813-1883), William Jenner, William Budd (1811-1886), Charles Murchison (1830-1879), J. H. F. Autenrieth (1777-1853), Heinrich Gustav Magnus (1802-1870), Huss and others. By the learned and accomplished Armand Trousseau British and German influences were carried into France.

Meanwhile Cohnheim and Mečtchikoff were engaged in destroying the ontological conception not of fever only, but also of inflammation, of which, as a local event, an ontological conception was no less strongly implanted. By his researches on the migration of the white corpuscles of the blood Cohnheim, on the bases laid by Virchow, brought the processes of inflammation within the scope of the normal, seeing in them but a modification of normal processes under perturbations of relatively external incidence; even the formation of abscess was thus brought by him within the limits of perversion of processes not differing essentially from those of health; and "new formations," "plastic exudations," and other discontinuous origins of an "essential" pathology, fell into oblivion. And it is not alien from the present point of view to turn for a moment to the light thrown on the cardio-arterial pulse and the measurement of its motions by the more intimate researches into the phenomena of the circulation by many observers, among whom in the 19th century James Hope, E. J. Marey (1830-1904) and C. F. W. Ludwig will always take a leading place. By them the demonstration of Harvey that the circulation of the blood is in large part a mechanical process, and nowhere independent of mechanical laws, was considerably enlarged and extended. In particular the fluctuations of the pulse in fevers and inflammations were better understood, and accurately registered; and we can scarcely realize now that before Harvey the pulse of the time seems not to have been counted by the watch. Discovery in these various directions then led physicians to regard fever and inflammation not as separable entities, but as fluctuating symptom-groups, due to swervings of function from the normal balance under contingent forces.

As to such reforms in our conceptions of disease the advances of bacteriology profoundly contributed, so under the stress of consequent discoveries, almost prodigious in their extent and revolutionary effect, the conceptions of the etiology of disease underwent no less a transformation than the conceptions of disease itself. It is proper to point out here how intimately a pathology thus regenerated modified current conceptions of disease, in the linking of disease to oscillations of health, and the regarding many of the modifications of the normal set up by the impingement of external causes; no few of which indeed may be generated within the body itself—"autogenous poisoning." The appreciation of such modifications, and of the working of such causes, has been facilitated greatly by the light thrown upon normal processes by advances in physiology; so dependent is each branch of knowledge upon the advances of contiguous and incident studies. To biological chemistry we have been deeply indebted during the latter half of the 19th century. In 1872, Hoppe-Seyler (1825-1893) gave a new beginning to our knowledge of the chemistry of secretion and of excretion; and later studies have increased the range of physiological and pathological chemistry by investigations not only into the several stages of albuminoid material and the transitions which all foodstuffs undergo in digestion, but even into the structure of protoplasm itself. Digestion, regarded not long ago as little more than a trituration and "coction" of ingesta to fit them for absorption and transfer them to the tissues, now appears as an elaboration of peptones and kindred intermediate products which, so far from being always bland, and mere bricks and mortar for repair or fuel for combustion, pass through phases of change during which they become so unfit for assimilation as to be positively poisonous. The formation of prussic acid at a certain period of the vital processes of certain plants may be given as an example of such phases; and poisons akin to muscarin seem to arise frequently in development or regression, both in animals and plants. Thus the digestive function, in its largest sense, is now seen to consist, not only in preparation and supply, but in no small measure also of protective and antidotal conversions of the matters submitted to it; coincidently with agents of digestion proper are found in the circuit of normal digestion "antidotoxins" which neutralize or convert peptones in these poisonous phases; an autochthonous ferment, such as rennet for instance, calling forth an anti-rennet, and so on. Now as our own bodies thus manipulate substances poisonous and antidotal, if in every hour of health we are averting self-intoxication, so likewise are we concerned with the various intruding organisms, whose processes of digestion are as dangerous as our own; if these destructive agents, which no doubt are incessantly gaining admission to our bodies, do not meet within us each its appropriate compensatory defensive agent, dissolution will begin. Thus, much of infection and immunity are proving to be but special cases of digestion, and teleological conceptions of protective processes are modified.

Under the name of chemotaxis (W. Pfeffer) are designated certain of the regulative adaptations by which such ends are attained. By chemical warnings the defensive processes seem to be awakened, or summoned; and when we think of the infinite variety of such possible phases, and of the multitude of corresponding defensive agents, we may form some dim notion of the complexity of the animal blood and tissues, and within them of the organic molecules. Even in normal circumstances their play and counterplay, attractive and repellant, must be manifold almost beyond conception; for the body may be regarded as a collective organization consisting of a huge colony of micro-organisms become capable of a common life by common and mutual arrangement and differentiation of function, and by toleration and utilization of each other's peculiar products; some organs, such as the liver, for example, being credited with a special power of neutralizing poisons, whether generated under normal conditions or under abnormal, which gain entrance from the intestinal tract. As a part of these discoveries has arisen another but kindred doctrine
of medicine. The approach of skilled pathologists to the clinical wards, a link is forged between practitioners and the men of science who pursue pathology disinterestedly. The first clinical line of duty to have been taken by von Zernike (1829-1907) at Munich, founded in 1883; and, although his example has not yet been followed as it ought to have been, enough has been done in this way, at Johns Hopkins University and elsewhere, to prove the vital importance of the system to the progress of modern medicine. At the same time provision must be made for the integration of knowledge as well as for the winning of it by several adits. A conspicuous example of the incalculable evil wrought by lack of integration is well seen in the radical divorce of surgery from medicine, which is one of the most mischievous legacies of the middle ages. One might almost say that which is so deeply rooted in our institutions, in the United Kingdom at any rate, as to be hard to obliterate. That the methods and the subject-matter of surgery and of medicine are substantially the same, and that the advance of one is the advance of the other, the division being purely artificial and founded merely on accidents of personal bent and skill, must be insisted upon at this time of our history. The distinction was never a scientific one, even in the sense in which the word science can be used of the middle ages; it originated in social conceptions and in the contempt for mechanical arts which came of the cultivation of the liberal faculties. In the several conditions of life, they vary so much about the mean as to have become almost if not quite alien one to another.

In the preservation of immunity then, in its various degrees and kinds, not only is the chemistry of the blood to be studied, but also its histology. By his eminent labours in cellular pathology, Virchow, and Metchinkoff later, gave the last blow to the mere humoral pathology which, after an almost unchallenged prevalence for some two thousand years, now finds a resting-place only in our nurseries. Now the cellular pathology of the blood, as revealed by the modern condition of life, is as important as that of the solid organs; no clinical investigator — indeed, apart from research, no practitioner at this day — can dispense with examination of the blood for purposes of diagnosis; its coagulability and the kinds and the variations of the cells it contains being evidence of many definitely morbid states of the body. Again, not only in certain diseases may strange cells be found in the blood (e.g., in myelogenic leukaemia), but parasites also, both in man, as those of malaria, of sleeping sickness, of kala-azar, and in animals, as redwater, Texas fever, n'gana, have been discovered, to the great advantage of preventive medicine. For some of these, as redwater (pyrosoma), antidoles are already found; for others, as for Texas fever — of which the parasite is unknown, but the mode of its transmission, by the mosquito, discovered (Finlay-Reed) — preventive measures are reducing the prevalence.

It is obvious that the results of such advances prescribe for the clinical physician methods which cannot be pursued without expert assistance; a physician engaged in busy practice cannot himself undertake even the verifications required in the conduct of individual cases. Skill in modern laboratory work is far out of the reach of the untaught as performance on a musical instrument. In spite, therefore, of the encyclopaedic tradition which has persisted from Aristotle through the Arab and medieval schools down to Herbert Spencer, it is forced upon us in our own day that in a pursuit so many-sided as medicine, whether in its scientific or in its practical aspect, we have to submit more and more to that division of labour which has been a condition of advance in all other walks of life. It is also universally recognized that diseases of infants and children, of the interior of the generative organs of women, of the larynx, of the eye, have been brought successively into the light of modern knowledge by "specialists," and by them distributed to the profession; and that in no other way could this end have been attained. That the division of labour, which may seem to disintegrate the calling of the physician, really unites it, is well seen in the clinical laboratories which were initiated in the later 19th century, and which are destined to a great future. By the approach of skilled pathologists to the clinical wards, a link is forged between practitioners and the men of science who pursue pathology disinterestedly. The first clinical line of duty to have been taken by von Zernike (1829-1907) at Munich, founded in 1883; and, although his example has not yet been followed as it ought to have been, enough has been done in this way, at Johns Hopkins University and elsewhere, to prove the vital importance of the system to the progress of modern medicine. At the same time provision must be made for the integration of knowledge as well as for the winning of it by several adits. A conspicuous example of the incalculable evil wrought by lack of integration is well seen in the radical divorce of surgery from medicine, which is one of the most mischievous legacies of the middle ages. One might almost say that which is so deeply rooted in our institutions, in the United Kingdom at any rate, as to be hard to obliterate. That the methods and the subject-matter of surgery and of medicine are substantially the same, and that the advance of one is the advance of the other, the division being purely artificial and founded merely on accidents of personal bent and skill, must be insisted upon at this time of our history. The distinction was never a scientific one, even in the sense in which the word science can be used of the middle ages; it originated in social conceptions and in the contempt for mechanical arts which came of the cultivation of the liberal faculties. In the several conditions of life, they vary so much about the mean as to have become almost if not quite alien one to another.

In the preservation of immunity then, in its various degrees and kinds, not only is the chemistry of the blood to be studied, but also its histology. By his eminent labours in cellular pathology, Virchow, and Metchinkoff later, gave the last blow to the mere humoral pathology which, after an almost unchallenged prevalence for some two thousand years, now finds a resting-place only in our nurseries. Now the cellular pathology of the blood, as revealed by the modern condition of life, is as important as that of the solid organs; no clinical investigator — indeed, apart from research, no practitioner at this day — can dispense with examination of the blood for purposes of diagnosis; its coagulability and the kinds and the variations of the cells it contains being evidence of many definitely morbid states of the body. Again, not only in certain diseases may strange cells be found in the blood (e.g., in myelogenic leukaemia), but parasites also, both in man, as those of malaria, of sleeping sickness, of kala-azar, and in animals, as redwater, Texas fever, n'gana, have been discovered, to the great advantage of preventive medicine. For some of these, as redwater (pyrosoma), antidoles are already found; for others, as for Texas fever — of which the parasite is unknown, but the mode of its transmission, by the mosquito, discovered (Finlay-Reed) — preventive measures are reducing the prevalence.

It is obvious that the results of such advances prescribe for the clinical physician methods which cannot be pursued without expert assistance; a physician engaged in busy practice cannot himself undertake even the verifications required in the conduct of individual cases. Skill in modern laboratory work is as far out of the reach of the untaught as performance on a musical instrument. In spite, therefore, of the encyclopaedic tradition which has persisted from Aristotle through the Arab and medieval schools down to Herbert Spencer, it is forced upon us in our own day that in a pursuit so many-sided as medicine, whether in its scientific or in its practical aspect, we have to submit more and more to that division of labour which has been a condition of advance in all other walks of life. It is also universally recognized that diseases of infants and children, of the interior of the generative organs of women, of the larynx, of the eye, have been brought successively into the light of modern knowledge by "specialists," and by them distributed to the profession; and that in no other way could this end have been attained. That the division of labour, which may seem to disintegrate the calling of the physician, really unites it, is well seen in the clinical laboratories which were initiated in the later 19th century, and which are destined to a great
into his professional studies. The founding of new teaching universities, in which England, and even France, had been at some disadvantage as compared with Scotland and Germany, strengthened the movement in favour of enlarging and liberalizing technical training, and of anticipating technical instruction by some broader scientific discipline; though, as in all times of transition, something was lost temporarily by a departure from the old discipline of the grammar school before a new scheme of training the mind in scientific habits and conceptions was established or fully apprehended. Yet on the whole, even from the beginning, the movement was successful in that it showed the position of the "docile physician," who took a literary, fastidious and meditative rather than an experimental interest in his profession, and, as in great part a descendant of the humanists, was never in full sympathy with experimental science. At the risk no doubt of some defects of culture, the newer education cleared the way for a more positive temper, awoke a new sense of accuracy and of verification, and created a sceptical attitude towards all conventions, whether of argument or of practice. Among the drawbacks of this temper, which on the whole made for progress, was the rise of a school of excessive scepticism, which, forgetting this school, whether in England or abroad, despised all degrees of moral certainty that, in so complex a study and so tentative a practice as medicine, must be our portion for the present, and even for a long future, however great the triumphs of medicine may become. This scepticism took form in the school, most active between 1860 and 1880, known as the school of "Expectant Medicine." These teachers, genuinely touched with a sense of the scantiness of our knowledge, of our confidence in abstract terms, of the insecurity of our alleged "facts," case-histories and observations, alienated from traditional dogmatism and disgusted by meddlesome polypharmacy—enlightened, moreover, by the issue of cases treated by means such as the homeopathic, which were practically "expectant"—urged the only course open to the physician, duly conscious of his own ignorance and of the mystery of nature, is to put his patient under diet and nursing, and, relying on the tendency of all equilibriums to recover themselves under perturbation, to await events (Vis medicatrix naturae). Those physicians who had occupied themselves in the study of the exact sciences, or more closely or more exclusively of the wreckage of the post mortem room, were the strongest men of this school, whether in England or abroad.

But to sit down helpless before human suffering is an undurable attitude. Moreover, the insight into origins, into initial morbid processes revealed by the pathologists, awoke more and more the hope of dealing with the elements of disease, with its first beginnings; and in the field of therapeutics, chemical and biological experiment, as in the case of digitals, mercury and the iodides, was rapidly simplifying remedies and defining their virtues, so that these agents could be used at the bedside with more precision. Furthermore, the aversion from drugs and disgusted by meddlesome polypharmacy—made the advantage of directing men's minds to remedies taken from the region of the physical forces, of electricity (G. B. Duchenne, 1866-1875), of gymnastics (Ling, 1776-1839), of hydropathy (V. Priessnitz), of massage (Weir Mitchell), of climate (James Clarke), of diet (R. B. Todd, King Chambers, &c.), and even of hypnotism (James Braid 1795-1860), while with the improvement of the means of locomotion came the renewal of the old faith and the establishment of new methods in the use of mineral springs. These and such means, often in combination, took much of the place formerly given to the use of drugs.

Again, a new spirit dictated the use of the physical or "natural" methods on a larger scale in the field of prevention.

Hygiene. From the new regard given by physiologists and pathologists to the study of origins, and in the new hopes of thus dealing with disease at its springs, not in individuals only but in cities and nations, issued the great school of Preventive Medicine, initiated in England—E. A. Parkes (1819-1876), J. Simon, Sir B. W. Richardson (1828-1896), Sir H. W. Acland (1815-1900), Sir G. Buchanan (1831-1895), and forwarded in Germany by Max von Pettenkofer (1818-1901). Hygiene became for pathology what "milieu" is for physiology. By the modification of physical conditions on a national scale a prodigious advance was made in the art of preventing disease. The ghastly roll of infantile mortality was quickly purged of its darkest features (Ballard and others); aided by bacteriology, sanitary measures attained some considerable degree of exactness; public medicine gained such an ascendency that special training and diplomas were offered at universities; and in 1875 a consolidated act was passed for the United Kingdom establishing medical officers of health, and responsible lay sanitary authorities, with no inconsiderable powers of enforcing the means of public health in rural, urban, port and other jurisdictions, with summary methods of procedure. A department of public health was formed within the precincts of the Local Government Board; government laboratories were established, and machinery was devised for the notification of infectious diseases. The enormous growth of towns during the second half of the 19th century was thus attended with comparative safety to these great aggregates of mankind; and the death-rates, so far from being increased, relatively decreased in substantial proportion, was perhaps most markedly in the case of the infectious diseases of animals. The establishment in England of the Register of qualified practitioners and of the General Medical Council (in 1858) did something, however imperfectly, to give unity to the profession, unhappily bisected by "the two colleges"; and did much to organize, to strengthen and to purify medical education and qualification. In 1876 women were admitted to the Register kept by the Council. In 1871 the Anatomical Act of 1832 was amended; and in 1876 the Vivisection Act was passed, a measure which investigators engaged in the medical sciences of physiology and pathology represented as likely to prevent in England the advance of knowledge of living function, both in its normal balance and in its aberrancies, and moreover to slacken that habit of incessant reference of propositions to verification which is as necessary to the clinical observer as to the experimentalist. However the opinion of later generations may stand in respect of the Vivisection Act, it will surely appear to them that the other acts, largely based upon the results of experimental methods, strengthening and consolidating the medical profession, and fortifying the advance of medical education, led directly to a fundamental change in the circumstances of the people in respect of health. The intelligent classes have become far better educated in the laws of health, and less disposed to quackery; the less intelligent are better cared for and protected by municipal and central authority. Thus the housing of the poor has been improved, though this difficult problem is yet far from solution; not the large towns only, but the larger villages also, are cleansed and drained; food has been submitted to inspection by skilled officers; water supplies have been undertaken on a vast scale; personal cleanliness has been encouraged, and with wonderful success efforts have been made to bring civilized Europe back from the effects of a long wave of Oriental asceticism, which in its neglect and contempt of the body led men to regard filth even as a virtue, to its pristine cleanliness under the Greeks and Romans. During the latter half of the 19th century the death-rate of many towns was reduced by something like 50%. Some plagues, such as typhus fever, have been dispelled; others, such as enteric fever, have been almost banished from large areas; and there is much reason to hope that cholera and plague, if introduced, could not get a footing in western Europe, or in any case could be combated on scientific principles, and greatly reduced. Tolerance in the use of alcohol has followed the demonstration not only of its unimportance as a food or tonic, but also of its harmfulness, save in very small quantities. In the earlier part of the 19th century, and in remoter districts even in its later years, the use of alcohol was regarded not as a mere indulgence, but as essential to health; the example of teetotalers, as seen in private life and in the returns of the insurance offices, has undermined this prepossession. From the time of Plato medicine has been accused of ministering to the survival of unfit persons, and to
their propagation of children. But bodily defect is largely a result of evil circumstances, in the prevention of which the physician is not unsuccessfully engaged, and the growth of sympathy means a stronger cement of the social structure. At any rate the mean standard of health will be raised, perhaps enormously.

In the tropics, as well as in Europe, such methods and such researches threw new light upon the causes and paths of the terrible infections of these climates. In 1880, two years before Koch discovered the bacillus of tubercle, C. L. A. Laveran (b. 1845) discovered the parasite of malaria, and truly conceived its relations to the disease; thus within two years were made two discoveries either of which was sufficient to make the honour of a century. Before the end of the 19th century this discovery of the blood parasite of malaria was crowned by the hypothesis of Patrick Manson, proved by Ronald Ross, that malaria is propagated by a certain genus of gnat, which acts as an intermediate host of the parasite. Cholera (Haffkine) and yellow fever are yielding up their secrets, and falling under some control. The 20th century, by means of this illumination of one of the darkest regions of disease, may diminish human suffering enormously, and may make habitable rich and beautiful regions of the earth's surface now, so far as man's work is concerned, condemned to sterility. Moreover, freedom of trade and of travel has been promoted by a reform of the antiquated, cumbersome, and too often futile methods of quarantine—a reform as yet very far from being achieved, but founded upon a better understanding of the nature and propagation of disease.

Special Departments.—Hitherto we have presented a survey of the progress of the science and practice of medicine on general lines; it remains to give some indication of the advance of these subjects of study and practice in particular departments. As regards infections, it is not to be supposed that our knowledge of these maladies has been advanced by pathology and bacteriology only. In the clinical field also it has received a great enlargement. Diphtheria, long thought a plague among mankind, was not carefully described until by Pierre Bretonneau in 1826, and since his time our conception of this disease has been extended by the study of later, secondary and incidental phases of it, such as neuritis, which had always formed part of the diphtheritic series, though the connexion had not been detected. Influenza, again, was well known to us in the 1836-1840, yet clinical observers had not traced out those sequelae which, in the form of neuritis and mental disorder, have impressed upon our minds the persistent virulence of this infection, and the manifold forms of its activity. By the discovery of the bacillus of tubercle, the physician has been enabled to perceive a long and varied list of maladies under several names, such as scrofula and lupus, many of them long suspected to be tuberculous, but now known to belong to the series. It is on clinical grounds that beriberi, scarlet fever, measles, &c., are recognized as belonging to the same class, and evolving in phases which differ not in intimate nature but in the more superficial and inessential characters of time, rate and polymorphism; and the impression is gaining strength that acute rheumatism belongs to the group of the infections, certain sore throats, chorea and other apparently distinct maladies being terms of this series. The field of disease arising not from essential defect in the body, but from external contingencies, is vastly enlarged; while on the other hand the great variability of individuals in susceptibility explains the very variable results of such extrinsic causes. Coincidently therewith, the hope of neutralizing infections by fortifying individual immunity has grown brighter, for it appears that immunity is not a very radical character, but one which, as in the case of vaccination, admits of modification and accurate adjustment in the individual, in no long time and by no very tedious methods. Evidence is accumulating which may end in the explanation, and perhaps in the prevention of the direst of human woes—cancer itself, though at present inquiry is being directed rather to intrinsic than to extrinsic causes.

When, leaving the infections, we look for evidence of progress in our knowledge of more or less local diseases, we may begin with the nervous system. It is in this department, from its abstruseness and complexity, that we should expect the advance of anatomy and physiology—normal and morbid—to be most delayed. If we consult the medical works even of the middle of the 19th century we shall find that, in the light of the present time, accurate knowledge in this sphere, whether clinical, pathological or therapeutical, could scarcely be said to exist. Even in the hands of J. A. Lockhart Clarke (1817-1880), one of the earliest investigators of nervous pathology, the improvement of the compound microscope had not attained the achromatism, the penetration and the magnification which have since enabled J. L. C. Schroeter-van der Kolk (1797-1862), Albert von Kölliker, Santiago Ramon y Cajal, C. Golgi (b. 1844) and others to reveal the minute anatomy of the nervous centres; while the discrimination of tissues and morbid products by means, as in the silver and osmic acid methods, and in those known by the names of Carl Weigert or Marchi, had scarcely begun. In England the Hospital for the Paralysed and Epileptic was founded in 1859, where Charles E. Brown-Séquard (1817-1894), J. Hughlings-Jackson, Thomas Buzzard, Henry C. Bastian (b. 1837), Sir W. R. Gowers and David Ferrier (b. 1843) founded an adequate field for the clinical and pathological parts of their work. In France, in the wards of the Hôtel Dieu, Guillaume Benjamin Duchenne (1806-1875), in association with Tronseau and in his private clinic, pursued his memorable clinical and therapeutic researches into the diseases of the nervous system; and Jean-Martin Charcot (1825-1893) in that asylum for the wreckage of humanity—the Salpêtrière—discovered an unworked mine of chronic nervous disease. M. H. Romberg (1795-1873) and Theodor Meynert (1833-1892) also were pioneers in the study of nervous diseases, but it was not till later in the century that Germany took a high place in this department of medicine. The discoveries of the separate paths of sensory and motor impulses in the spinal cord, and consequently of the laws of reflex action, by Charles Bell and Marshall Hall respectively, in their illumination of the phenomena of nervous function may, as connected with the discovery of the region of the vascular system of the circulation of the blood; for therein a key to large classes of normal and aberrant functions and a fertile principle of interpretation were obtained. Nor was the theory of reflex action confined to the more "mechanical" functions. By G. H. Lewes and others the doctrine of "cerebral reflex" was suggested, whereby actions, at first achieved only by incessant attention, became organized as conscious or subconsciously habits; as for instance in the playing on musical or other instruments, when acts even of a very delicate character are performed directly from the impulses of sensations, conscious adaptation and the deliberate choice of means being thus economized. This law has important ethical and political bearings; but in the province of disease this advance of what may be compared to the interlocking of points and signals has had wide influence not only in altering our conceptions of disease, but also in enlarging our views of all perturbations of function. The grouping of reflex "units," and the paths wherein impulses travel and become associated, have been made out by the physiologists (Sherrington and others) working on the healthy animal, as well as by the record of disease; and not of spontaneous disease alone, for the artificial institution of worthy diseases in animals has led to many of these discoveries, as in the method of A. V. Waller (1816-1879), who tracked the line of nervous strands by experimental sections, and showed that when particular strands are cut off from their nutritive centres the consequent degeneration follows the line of the separated strands. By similar methods nature, unassisted, betrays herself but too often; in many instances—probably originating primarily in the nervous tissues themselves—the course of disease is observed to follow certain paths with remarkable consistency, as for instance in diseases of particular tracts of the spinal cord. In such cases the paths of degeneration are so neatly defined that, when the tissues are prepared after death by modern methods, they are plainly to be seen running along certain columns, the subdivisions
of which in the normal state may hardly be distinguishable one from another: some run in strips along the periphery of the spinal cord, at its anterior, middle or posterior segments; by case may be; in other cases such strips occur within its substance, whether along columns of cells or of white matter. It is needless to point out how such paths of disease, in their association with characteristic symptoms, have illuminated the clinical features of disease as well as the processes of normal function.

Not, however, all diseases of the nervous system conduct themselves on these definite paths, for some of them pay no attention to the geography of structure, but, as one may say, blunder indiscriminately among the several parts; others, again, pick out particular locations, either immediately contiguous, or even contiguous. Diseases of the latter kind are especially interesting, as in them we see that parts of the nervous structure, separated in space, may nevertheless be associated in function; for instance, wasting of a group of muscles associated in function may depend on a set of central degenerations concurring in parts whose connexion, in spite of dissociation in space, we thus perceive. The undiscriminating diseases, on the other hand, we suspect not to be primarily of nervous origin, but to depend rather on the agency of other constituent tissues of the system, and of the nervous elements. That, arguing inversely, we may learn something of the respective natures of these influences and of the way in which the nervous system is affected secondarily.

Yet even the distribution of toxic matters by the blood is not necessarily followed by general and indiscriminate injury to the nervous elements. In infantile palsy, for example, and in tubes dorsalis, there is good reason to believe that, definitely as the traces of the disease are found in certain physiologically distinct nervous elements, they are due nevertheless to toxic agents arriving by way of the blood. Here we enter upon one of the most interesting chapters of disorders and modes of disorder of this and of other systems. It has come out more and more clearly of late years that poisons do not betray even an approximately indifferent affinity for all tissues, which indeed a little reflection would tell us to be a priori improbable, but that each tends to fix itself to this cell group or to that, picking out parts for which they severally have affinities. Chemical, physiological and pathological research is exploring the secret of these more refined kinds of "anchorage" of molecules. In 1835, W. C. Young proved that blood was not all the same, but also that a substitution of molecules in certain compounds a stimulant could be converted into a sedative action; thus by the addition of the methyl group CH₃ to the molecule of strychnine, thebaine or brucine, the tetanizing action of these drugs is converted into a paralyzing action. The number of these instances, and the variety of them, are now known to be very large; and it is supposed that what is true of these simpler agents is true also of far more elaborate phases of vital metabolism. Now, what is remarkable in these and many other reactions is not only the effects apparently very opposite may result from minute differences of molecular construction, but also that, whatever the construction, agents, not wholly indifferent to the body or part, tend to anchor themselves to organic molecules in some way akin to them. Highly complex as are all animal tissues, or nearly all, yet in this category of high complexity are degrees higher and higher again of which we can form little conception, so elaborate they are, so peculiar in their respective properties, and probably so fugitive. It is this wide range of dynamic peculiarities above the common range of known physical and chemical molecules which excites our wonder; and a reflection of these peculiar properties is seen in their affinities for this or that toxic or constructive agent, whereby the peculiarity, for example, of a particular kind of nerve cell may be altered, antagonized, reinforced or converted. On the other hand, the reagents by which such modifications are apt to be produced are not necessarily simple; many of them likewise are known to be of very high degrees of complexity, approaching perhaps in complexity the molecules to which they are akin. Of such probably are the toxins and antitoxins of certain infections, which, anchoring themselves not by any means exclusively, like the peculiarly modified molecules, by such anchorage antagonize them or turn them to favourable or unfavourable issues. Toxins may thus become so closely keyed into their corresponding atom groups, as for instance in tetanus, that they are no longer free to combine with the antitoxin; or, again, an antitoxin injected before a toxin may anticipate it and, preventing its mischievous adhesion, dismiss it for excetration. In the mutual behaviour of such cells, toxins, and antitoxins, and again of microbes themselves, we may demonstrate even on the field of the microscope some of the modes of action, which seem to partake in great measure at any rate of a chemical quality (agglutinins, coagulins, chemotaxis). It is convenient here to add that such reactions and modifications, if more conspicuous in the nervous system, are of course not confined to it, but are concerned in their degree in all the processes of metabolism, being most readily traced by us in the blood.

Many other diseases formerly regarded as primarily diseases of the nervous system are not such; but, by means of agents either introduced into the body or modified there, establish chemical reactions after the affinities of these in contiguous associated parts of the structure, more or less peculiar to the nervous elements, or again in distant and peripheral parts; the perturbations of nervous function being secondary and consequent. Of such are tetanus and diphtheria, now known to be due to the establishment from without of a local mycobic infection, from which focus a toxin is diffused to the nervous matter. The terrible nervous sequel of some forms of inflammation of the membranes of the brain, again, are due primarily to microbic invasion rather of the membranes than of their nervous contents; and many other diseases may be added to these. The grave pulsies in such diseases as influenza, diphtheria, beriberi, or ensuing on the absorption of lead, are in the main not central, but due to a symmetrical peripheral neuritis.

Among diseases not primarily nervous, but exhibited in certain phenomena of nervous disorder, are diseases of the blood-vessels. Much light has been thrown upon the variations of arterial and venous blood pressures by Karl Ludwig (1816-1883) and his many followers: by them not only the diseases of the circulatory system itself are explained, but many nervous symptoms which are nervous, for instance—which depend intimately on the mechanical integrity of the circulation of the blood as well as on the chemical integrity of the blood itself. With changes of the pressures of the blood in arteries, veins or capillaries, and in the heart itself and its respective chambers, static changes are apt to follow in these parts; such as degeneration of the coats of the arteries, due either to the silent tooth of time, to persistent high blood pressures, or to the action of poisons such as lead or syphilis. Syphilitic lesion of the arteries, and likewise of other fibrous tissues, often involves grave consequential damage to nervous structures fed or supported by such parts. Some of the most successful of the advances of medicine as a healing art have followed the detection of syphilitic disease of the vessels, or of the supporting tissues of nervous centres and of the peripheral nerves; so that, by specific medication, the treatment of paralytic, convulsive, and other terrible manifestations of nervous disease thus secondarily induced is now undertaken in early stages with definite prospect of cure.

Not of less importance in this respect, and in other disorders many of them of grave incidence, is the knowledge of the phenomena of embolism and of thrombosis, also gained during the latter half of the 19th century—W. S. Kikites (1823-1864), R. Virchow. By embolism is meant the more or less sudden stoppage of a vessel by a plug of solid matter carried thither by the current of the blood; be it a little clot from the heart or, what is far more pernicious, an infective fragment from some focus of infection in the body, by which messengers new foci of infection may be scattered about the body. Thrombosis is an accident
of not dissimilar character, whereby a vessel is blocked not by a travelling particle, but by a clotting of the blood in situ, probably on the occasion of some harm to the epithelial lining of the vessel. Such injuries are apt to occur in syphilitic endarteritis, or senile arterial decay, whereby an artery may be blocked permanently, as it with an embolus, and the area supplied by it, in so far as it was dependent upon this vessel, deprived of nutrition. These events, although far more mischievous in the brain, the functions of which are far-reaching, and the collateral circulation of which is ill-provided, are seen very commonly in other parts.

It is in the structure of the brain itself that modern research has attained the most remarkable success. In 1861 an alleged "centre" of speech was detected, by a combination of clinical and pathological researches, by Paul Broca (1824-1880). By these means also, in the hands of Hughes-Jackson, and more conclusively by experimental research initiated by G. T. Fritsch (b. 1836) and J. E. Hitzig (b. 1836), but pursued independently and far more systematically and thoroughly by David Ferrier (b. 1843) and his disciples, it was proved that the cerebral cortex is occupied by many such centres or exchanges, which predate over the formulation of sensations into purposive groups of motions—kinaesthesia of H. Charlton Bastian (b. 1837). The results of these experimental researches by many inquirers into the constitution of the brain have transformed our conceptions of cerebral physiology, and thrown a flood of light on the diseases of the brain. Not only so, but this mapping of the brain in animals has often enabled us to attack the mental determinate the position of disease; in a certain few cases of tumour or abscess, so precisely that he may be enabled to open the skull above the part affected and to extirpate it—operations which are surely a triumph of science and technical skill (Lister, W. MacEwen, V. Horsley).

The remarkable discovery of the dual nature of the nervous system, of its duplex development as a lower and upper system of "neurons," has shed much light upon the problems of practical medicine, but this construction is described under Brain; Neuropathology; Muscle and Nerve, &c.

In mental diseases little of importance has been done. The chief work has been the detection of chronic changes in the cortex of the brain, by staining and other histological methods, in degenerative affections of this organ—Theodor Meynert (1833-1892), W. Griesinger (1817-1868), Bevan Lewis—and in the separation from insanity due to primary disease or defect of nerve elements of such diseases as general paralysis of the insane, which probably arise, as we have said, by the action of poisons on contiguous structures—such as blood-vessels and connective elements—and invade the nervous matter secondarily. Some infections, however, seem to attack the mental fabric directly; intrinsic toxic processes which may be suspected on the detection of neurin and cholrin in the fluids of the brain (F. W. Mott). Truer conceptions of normal psychology have been made for the first time by Morbid—P. Pinel (1745-1826), Griesinger, Henry Maudsley (b. 1835), Mercier, Kräpelin, Rivers—and indicated more truly the relations of sanity to insanity. In the treatment of insanity little has been done but to complete the non-restraint system which in principle belongs to the earlier part of the 19th century (Pinel, Tuke, R. G. Hill, J. B. Collot). An enormous accumulation of lunatics of all sorts and degrees seems to have paralysed public authorities, who, at vast expense in buildings, mass them more or less indiscriminately in barracks, and expect that their sundry and difficult disorders can be properly studied and treated by a medical superintendent charged with the whole domestic establishment, with a few young assistants under him. The life of these insane patients is as bright, and the treatment as humane, as a barrack life can be; but of science, whether in pathology or medicine, there can be little. A considerable step in advance is the establish-ment by the London County Council of a central laboratory for the examination of excreta at its hospitals, this laboratory valuable reports are in course of issue. Provision for the reception and treatment of insanity in its earliest and most curable stages can scarcely be said to exist. Sufferers from mental disease are still regarded too much as troublesome persons to be hidden away in humane keeping, rather than as cases of manifold and obscure disease, to be studied and treated by the undisquisition of physicians of the highest skill. The care and education of idiots, initiated by Guggenbuhl and the infection making way in England, and if as yet insufficient, is good of its kind.

By the genius of René Théophile Laennec (1781-1826), diseases of the lungs and heart were laid on a foundation so broad that his successors have been occupied in detail and refinement rather than in reconstruction. In heart disease the chief work of the latter half of the 19th century was, in the first quarter, such clinical work as that of William Stokes and Peter Mere Latham (1759-1875); and in the second quarter the fuller comprehensions of the vascular system, central and peripheral, with its cycles and variations of blood pressure, venous and arterial. Moreover, the intricacies of structure and function within the heart itself have been more fully discriminated (W. H. Gaskell, Aschoff, A. Keith, Wenkebach, J. Mackenzie). By the greater thoroughness of our knowledge of the physics of the circulation—Etienne Marey (b. 1830), Karl Ludwig (1801-1895), Leonard Hill—we have attained to a better conception of such events as arterial disease, apoplexy, "shock," and so forth; and pharmacologists have defined more precisely the virtues of curative drugs. To the discovery of the parts played in disease by thrombosis and embolism we have referred above. With this broader and more accurate knowledge of the changes in the health of the circulation a corresponding efficiency has been gained in the manipulation of certain medicines and new methods of treatment of heart diseases, especially by baths and exercises.

As regards pulmonary disease, pneumonia has passed more and more definitely into the category of the infections: the modes of invasion of the lungs and pleura by tuberculosis has been more and more accurately followed; and the treatment of these diseases, in the spheres both of prevention and of cure, has undergone a radical change. Instead of the close protection from the outer air, the respirators, and the fancy diets of our fathers, the modern practitioner must lay it to heart in all weathers, is fed with solid food, and in his exercise and otherwise is ruled with minute particularity according to the indications of the clinical thermometer and other symptoms. The almost reckless reliance on climate, which, at Davos for instance, marked the transition from the older to the modern methods, has of late been sobered, and supplemented by more systematic attention to all that concerns the mode of life of the invalid. The result is that, both in physicians and in the public, a more hopeful attitude in respect of the cure of phthisis has led to a more earnest grappling with the problem of its earliest stages and in every phase, with a corresponding larger hope brought: these new methods to bear fruit. Indeed, in such early stages, and in patients who are enabled to command the means of an expensive method of cure, phthisis is no longer regarded as desperate; while steps are being taken to provide for those who of their own means are unable to obtain these advantages, by the erection of special sanatoriums on a more or less charitable basis. Perhaps now advance in medicine has done so much as the study of tuberculosis to educate the public in the methods and value of research in medical subjects, for the results, and even the methods, of such labours have been brought to bear not only on the public and their friends, but also to the farmer, the dairyman, the butcher, the public carrier, and, indeed, to every home in the land.

It was in the management of pleurisies that the aid of surgical means first became eminent in inward disease. In the treatment of effusions into the pleura and, though with less advantage, of pericardial effusions, direct mechanical interference was practised by one physician and another, till these means of attaining rapid and complete cure took their places as indispensable, and were extended from thoracic diseases to those of the abdominal and other inner parts formerly beyond the reach of direct therapeutics. Lord Lister's discovery brought these new methods to bear with a certainty and a celerity previously undreamed of; and many visceral maladies, such as visceral ulcers, disease of the pancreas,
stone of the kidney or gall-bladder, perityphlitis, ovarian dropsey, which in the earlier part of the 19th century were either fatal or crippling, are now taken promptly and safely in hand, and dealt with successfully. Even for internal cancer cure or substantial relief is not infrequently obtained. We have said that this advance is often quoted, not very wisely, to signify that in modern progress medicine " has fallen behind surgery—as if the art of the physician were not both impervious and indispensable. If the College of Physicians (especially in gynecology) have personally taken operative procedures in hand is some good omen that in time the unreal and miserable schism between medicine and surgery may be bridged over.

In the department of abdominal disease progress has been made, not only in this enormous extension of means of cure by operative methods, but also in the verification of diagnosis. The first recognition of a disease may be at a necropsy, but then usually by irresponsible pathologists; it is another matter when the physician himself comes under repute for failing to seize a way to cure, and the chance remained to him, by section of the abdomen during life. The abdomen is still " full of surprises "; and he who has most experience of this deceptive region will have least confidence in expressing positive opinions in particular cases of disease without operative investigation. Besides the attainments mentioned above, in respect of operative progress, many important revisions of older rule-of-thumb knowledge have come about, and not a few other substantial discoveries. Among the revisions may be added some addition to our knowledge of dyspepsia, attained by analytic investigations into the contents of the stomach at various stages of digestion, and by examination of the so-called mucus of the organ obtained through the prince 
\varepsilon s by the Röntgen rays. Thus the defects, whether of this secretion or of that, and again of motor activity, the state of the valvular junctions, the volume of the cavities, and their position in the abdomen, may be ascertained, and dealt with as far as may be; so that, although the fluctuations of chemical digestion are still very obscure, the application of remedies after a mere traditional routine is no longer excusable. In our conceptions of the later stages of assimilation and of excretion, with the generation of poisons (auto-intoxication) in the intestinal tract, there is still much obscure; and much guess-work; yet in some degree the positive knowledge has been gained, partly by the physiologist, partly by the physician himself. Of such are the better understanding of the functions of the liver in normal catabolism, in the neutralization of poisons absorbed from the intestines or elsewhere, in the causation of jaundice, and in diabetes [Bernhard Naunyn (b. 1830) and F. W. Pavy]. Nor must we forget the unfolding of a new chapter of disease, in the nosology of the pancreas. In diabetes this organ seems to play a part which is not yet precisely determined; and one fell disease at least has been traced to a violent access of inflammation of this organ, caused perhaps by entry of foreign matters into its duct. The part of the pancreas in digestion also is better understood. The part of the spleen in the motley group of dyspepsias and anæmias, conspicuous as it often is, still remains very enigmatic.

The peritonæum is no longer regarded with awe as inviolable; by modern methods, if not as manageable as other lymphatic sacs, it is at any rate accessible enough without considerable risk to life. Not only in its bacteriological relations are the conditions of peritonitis recognized in its various kinds, but also the state known as shock turns out to be quasi-mechanical, and avoidable by measures belonging in considerable part to this category. Thus, by the avoidance both of toxemia and of shock, peritonitis and other dangers of the abdomen, such as strangulations or intussusceptions of the bowels, formerly desperate, can in many cases be dealt with safely and effectively.

Our knowledge of diseases of the kidneys has made no great advance since the time of Richard Bright. In the sphere of physiology and in the interpretation of associated arterial diseases much obscurity still remains; as, for instance, concerning the nature of the toxic substances which produce those bilateral changes in the kidneys which we call Bright's disease, and bring about the " uremia " which is characteristic of it. Lardaceous disease, however, here and in other regions, now appears to be due to the specific toxins of pyrogenic micro-organisms. In stone of the kidney a great advance has been made in treatment by operative means, and the formation of these stones seems to recent observers to depend less upon constitutional bent (gout) than upon unhealthy local conditions of the passages, which in their turn again may be due to the action of microorganisms previously unrecognised. And the illustrations of this inconsiderable bodies and of the pituitary body in sustaining arterial blood pressures physiologists have thrown some important light.

The secret of the terrible pueteral septicaemia was read by J. P. Semmelweis (g.v.), wherein he proved himself to be the greatest of List's forerunners (see Lister). The "diseases peculiar to women" (see GYNECOLOGY) have given the attention that the site, characters and treatment of these; the middle occupy of the physician becoming in the temperament of woman a morbid obsession. To James Matthews Duncan (1826-1890) we chiefly owe a saner and broader comprehension of the relative importance of the local and the general conditions which enter into the causation of uterine and ovarian disorders. In operations for diseases of the pelvis, ovarian dropsey, cancer of the uterus, and other grave diseases of the region, success has been stupendous.

In the subject of diseases of the skin much has been done, in the minuter observation of their forms, in the description of forms previously unrecognized, and in respect of bacterial and other causation and of treatment. The comparison of observations in various climates and peoples has had some weight; while in the better knowledge of their causes their treatment has found permanent advantage. Not only is the influence of bacteria in the causation of many of them newly revealed, but it is now recognized also that, even in skin diseases not initiated by microbic action, microbes play a considerable and often a determining part in their perpetuation; and that the rules of modern aseptic surgery are applicable with no little success to skin therapeutics. We have learned that " constitutional " causes play a smaller part in them than was supposed, that a large number of diseases of the skin, even if initiated by general disorder, are or soon become local diseases, being, if not initiated by local infection yet perpetuated thereby, so that, generally speaking, they are to be cured by local means.

The diseases of children have not lacked the renewed attention, the successful investigation, and the valuable new lights which have been given to other departments of medicine. That infantile paralysis is an infection, and that its unhappy sequels are now treated with more hope of restoration, has been indicated already. Infantile diarrhoea has also been recognized as a common infection (Ballard), and the means of its avoidance and cure ascertained. The conditions of diet and digestion in children are now far better understood, and many of their maladies, formerly regarded as organic and incomprehensible, are cured or relieved by dietary rules. Rickets, scurvy and " marasmus " may be instanced as diet diseases in children. Acute inflammation of the ear, with its alarming extensions to the cerebral cavity, is now dealt with successfully by surgical means, and infected sinuses or even encephalitic abscesses are reached and cleansed. The origins, kinds and processes of meningitis are more clearly discerned, and referred each to its proper cause —for the most part bacterial.

As by the discovery of theluocytosis by Laennec a new field of medical science and art was opened up, so, more recently, inventions of other new methods of investigation in medicine...
MEDINA, J. T.—MEDINA

It is interesting to find that, with all this activity in the present reformed methods of research and verification are not confined to the work of the passing day; in the brilliant achievements of modern research and reconstruction the maxim that "Truth is the daughter of Time" has not been forgotten. In the field of the History of Medicine the work of scholars such as Francis Adams of Banchory (1756-1861), William A. Greenhill (1814-1894) and C. Creighton in England, Maximilien P. Littre (1801-1881) and Charles V. Daremberg (1817-1872) in France, and Heinrich Häser (1811-1888) and August Hirsch, Diels, Wettmann and Julius Pagel in Germany, will prove to our children that tradition was as safe in our hands as progress itself.

MEDINA, JOSE TORIBIO (1852— ), Chilean bibliographer, was born at Santiago, and was educated for the bar. His first publication, when a very young man, was a metrical translation of Longfellow's Evangeline. When twenty-two he was appointed secretary to the legation at Lima. After his return he published a history of Chilean literature (1878), and a work upon the aboriginal tribes (1884). In this latter year he was appointed secretary of legation in Spain, and availed himself of the opportunity of examining the treasures of the old Spanish libraries. These researches, repeated on subsequent visits to Spain, and also to France and England, enriched him with a mass of historical and bibliographical material. Among his works may be mentioned the Biblioteca hispano-americana, a catalogue of all books and pamphlets relating to Spanish America printed in Spain; the Biblioteca hispano-chilena, a similar work, commenced in 1897; the standard and magnificent history of printing in the La Plata countries (1892); comprehensive works on the Inquisition in Chile, Peru and the Philippines; and the standard treatise on South American medals (1890). In addition, Señor Medina produced the fullest bibliographies yet attainable of books printed at Lima, Mexico and Manila, and a number of smaller works and other minor writings. No other man had rendered anything like the service of Medina in the field of the literary history and bibliography of the Spanish colonies.

MEDINA, or rather AL-MEDINA (the city), or MEDINAT RASUL ALLAH (the city of the apostle of God), a town of the Hejaz in Arabia, about 820 m. by rail S.S.E. of Damascus, in 25° N., 46° E., the refuge of Mahomet on his emigration from Mecca, and a renowned place of Moslem pilgrimage, consecrated by the possession of his tomb. The name Medina goes back to the Koran (sur. xxxiii. 60); the old name was Yahrib, the Lathrippa of Ptolemy and Lathrippa of Stephanus Byzantius.

Medina stands in a basin at the northern extremity of an elevated plain, on the western skirt of the mountain range which divides the Red Sea coast-lands from the central plateau of Arabia. At an hour's distance to the north it is dominated by Mount Ohod, an outlying spur of the great mountains, the scene of the well-known battle (see MAHIOMET), and the site of the tomb and mosque of the Prophet's uncle Hamza. To the east the plain is bounded by a long line of hills eight or ten hours distant, over which the Nejd road runs. A number of torrent courses (of which Wadi Kanat at the north, the foot of Mount Uhud, and W. Ar-Ab or some miles to the south, are the most important) descend from the central plateau, to the northern and eastern sides of the neighbourhood of the town to unite farther west at a place called Zaghba, whence they descend to the sea through the "mountains of the Tehama"—the rough country between Medina and its

1 This is a very rough estimate. The road from Yambu on the Red Sea, which runs somewhat north of east, is by Burton's estimate 132 m. From Medina to Mecca by the inland or high road he makes 245 m. The usual road near the coast by Tabibig and Khulesa and thence to W. Fatima cannot be very different in length. Caravans traverse it in about ten or eleven days.
port of Yambo—under the name of W. Idam. Southwards from Medina the plain extends unbroken, but with a slight rise, as far as the eye can reach. The convergence of torrent-courses in the neighbourhood of Medina makes this one of the best-watered spots in northern Arabia. The city lies close to one of the great volcanic centres of the peninsula, which was in violent eruption as late as A.D. 1266, when the lava stream approached within an hour's distance of the walls, and damsmed up W. Kanat. The result of this and older prehistoric eruptions has been to confine the underground water, so important in Arabian tillage, which can be reached at any point of the oasis by sinking deep wells. Many of the wells are brackish, and the natural salinity of the volcanic soil is in many places impaired by the salt with which it is impregnated; but the date-palm grows well everywhere, and the groves, interspersed with gardens and cornfields, which surround the city on all sides except the west, have been famous from the time of the Prophet. Thus situated, Medina was originally a city of agriculturists, not like Mecca a city of merchants; nor, apart from the indispensable trade in provisions, has it ever acquired commercial importance like that which Mecca owes to the pilgrimage. Landowners and cultivators and cultivators and cultivators are the popular type of Medina. The latter, who are called Nakhāwila, and more or less openly profess the Shi'a opinion, marry only among themselves. The townsman proper, on the other hand, are a very motley race.2 New settlers remain behind with each pilgrimage; attracted by the many offices of profit connected with the mosque, the stipends paid by the sultan to every inhabitant, and the gains to be derived by pilgrim-cicerones (Muwawir) or by those who make a business to say prayers at the Prophet's mosque for persons who send a fee from a distance, as well as the alms which the citizens are accustomed to collect when they go abroad, especially in Turkey. The population of the city and suburbs may be from 16,000 to 20,000.

The city proper is surrounded by a solid stone wall,3 with towers and four massive gateways of good architecture, forming an irregular oval running to a kind of angle at the north-west, where stands the castle, held by a Turkish garrison. The houses are good stone buildings similar in style to those of Mecca; the streets are narrow but clean, and in part paved.4 There is a copious supply of water conducted from a tepid source (ez-Zarkh) at the village of Kub, 2 m. south, and distributed in underground cisterns and in the arcades of the great Mosque of Medina.4 One of the most important buildings, is the mosque of the Prophet, in the eastern part of the city, a spacious enclosed court between 400 and 500 ft. in length from north to south, and two-thirds as much in breadth. The minarets and the lofty dome above the sacred graves are imposing features; but the circuit is hemmed in by houses or narrow lanes, and is not remarkable except for the principal gate (Bab al-Salam) at the southern end of the west front, facing the sacred graves, which is richly inlaid with marbles and fine tiles, and adorned with golden inscriptions. This gate leads into a deep portico, with ten rows of pillars, running along the southern wall. Near the farther end of the portico, but not at a general concourse at one time, and no fair like that of Mecca.

A small number of families in Medina still claim to represent the 1st ab. D. A. He, the "defenders" of Medina; there are also some Siddiqis, claiming descent from Abu Bekr. But it is natural that the old population emigrated en masse after the sack of Medina by the Persians in 683, and that there was no great influx of strangers when the place was opened up for repairs. Ibn Jubair (p. 103 seq.) and Samhūlī speak of a small casket adorned with silver, fixed in the eastern wall, which was supposed to be opposite the head of the Prophet, while a silver nail in the south wall indicated the point to which the corpse faced, and from which the salutation of worshippers was to be addressed (Burton misquotes). The European fable (mentioned and refuted, e.g. in Histoire des Arabes par l'abbé de Marigny, t. i. p. 46, Paris, 1750) of the coffin suspended by magnets is totally unknown to Moslem tradition. The smaller chamber of Fatima is comparatively modern. In the time of Ibn Jubair and of Ibn Batuta (unless

1 The pilgrimage to Medina, though highly meritorious, is not obligatory, and to a great extent has been superseded by a visit to a similar place in Timbucout. So that there is no general concourse at one time, and no fair like that of Mecca.

2 A small number of families in Medina still claim to represent the 1st ab. D. A. He, the "defenders" of Medina; there are also some Siddiqis, claiming descent from Abu Bekr. But it is natural that the old population emigrated en masse after the sack of Medina by the Persians in 683, and that there was no great influx of strangers when the place was opened up for repairs. 3 The space between the railing and the tomb is seldom entered except by the servants of the mosque. It contains the treasures of the mosque in jewels and plate, which are once very considerable, but have been repeatedly plundered, last of all by the Wahhabis in the beginning of the 19th century.

4 The word ra'ida also means a mausoleum and is applied by Ibn Jubair to the tomb itself. Thus the tradition that the space between the pupil and the tomb was called by the Prophet one of the gardens of Paradise probably arose from a mistake.
MEDINA—MEDINA SIDONIA, DUKE OF

the latter, as is so often the case, is merely copying his prede-
cessor) there was only a small marble trough north of the rauđa
(or grave) which "is said to be the house of Fatima or her
grave, but God only knows." It is more probable that Fatima
was buried in the Bākī, where her tomb was also shown in the
13th century (Ibn Jubair, pp. 190, 221). The

The mosque was again extended by the caliph Mahādī (A.D. 781)
and was burned down in 1256. Of its appearance before the fire
we have two authentic accounts by Ibn 'Abd Rabbīh early in
the 10th century, and by Ibn Jubair, who visited it in 1184. The
old mosque had a much finer and more regular appearance than
the present one; the interior walls were richly adorned with marble
and mosaic arabesques of trees and the like, and the outer walls
with stone marquetry; the pillars of the south portico (seventeen
in each row) were in white stone without gilt capitals, the other
pillars were of marble. Ibn 'Abd Rabbīh speaks of eighteen
gates, of which in Ibn Jubair's time, as at present, all but four
were walled up. There were then three minarets. After the
fire which took place just at the time of the fall of the caliphate,
the mosque long lay in a miserable condition. Its repair was
chiefly due to the Egyptian sultans, especially to Kālīt Bey,
whose restoration after a second fire in 1481 amounted almost to
a complete reconstruction. Of the old building nothing seems
to have remained but some of the columns and part of the
walls. The minarets have also been rebuilt and two new ones
added. The dome above the mihrāb, or prayer niche, has been
round it, and the pulpit, all date from Kālīt Bey's restoration.

The suburbs, which occupy as much space as the city proper,
and are partly walled in, lie south-west of the town, from which
they are separated by an open space, the halting-place of cara-
vans. Through the suburbs runs the watercourse called Wādi
Buthan, a tributary of W. Kanāt, which the Yanbu' road crosses
by a stone bridge. The suburbs are the quarter of the peasants.
Thirty or forty families with their cattle occupy a single court-
yard (bškh), and form a kind of community often at feud with
its neighbours. This provision was made in the same way as at the time of the Prophet. The famous
cemetery called Bākī' el-Gharkād, the resting-place of a multi-
tude of the "companions" of the Prophet, lies immediately to
the west of the city. It once contained many monuments, the
chief of which are described by Ibn Jubair. Burckhardt in 1815
found it a mere waste, but some of the mosques have since been
rebuilt.

History. — The story of the Amalekites in Yathrib and of their
conquest by the Hebrews in the time of Moses is purely fabulous
(see Nöldeke, Über die Amalekiten, 1884, p. 36). The oasis, when
it first comes into the light of history, was held by Jews, among
whom emigrants from Yemen afterwards settled. From the
time of the emigration of Mahomet (A.D. 622) till the Omayyads
removed the seat of empire from Medina to Damascus, the town
springs into historic prominence as the capital of the new power
that so rapidly changed the fate of the East. Its fall was not
less rapid and complete, and since the battle of Harra and the
sack of the city in 683 it has never regained political importance
(see CALIPHATE, B. §§ 1, 2, &c.). Mahomet invested the country
round Medina with an inviolable character like that of the Haram
round Mecca, and his provisions were observed with strictness.
After the fall of the caliphs, who maintained a
governor in Medina, the native amirs enjoyed a fluctuating
measure of independence, interrupted by the aggressions of the
sherifs of Mecca, or controlled by an intermittent Egyptian
protectorate. The Turks after the conquest of Egypt held
Medina for a time with a firmer hand; but their rule grew weak,
and was almost nominal long before the Wahhābīs took the city
in 1804. A Turk–Egyptian force retook it in 1812, and the
Turks now maintain a pasha with a military establishment, while
the cadi and chief digna of the mosque (a eunuch) are sent from
Constantinople. In late years the influence of the Turkish
government has been much strengthened, an important factor in
its consideration being the construction of the railway from Syria
to the Hejaz. Railway communication between Damascus and
Medina was effected in 1908.

Authorities. — Medina has been described from personal observation
by Burckhardt. He visited it in 1815, and Burton, who made
the pilgrimage in 1853. Sadrīdī on his journey from Kafrī to Yambūn
(1819) was not allowed to enter the holy city. Burckhardt was
prevented by ill-health from examining the city and country with
the thoroughness that he afterwards attacked the north of the
report of 'Abd el-Razzāqī, who performed the pilgrimage in 1878,
who medical commission from the English government. The
chief Arabic authority besides Ibn 'Abd Rabbīh and Ibn Jubair
is Samī'īdī, of whose history of Medina and its environs in the
Göttingen Abhandlungen, vol. ix. (1861). It goes down to
the end of the 15th century. The topography of the country about
Medina is charmingly described by geographicalically; Baleari,
Yāqūt and other Arabic geographers, supply much material on
this topic. Some good information concerning Medina is contained
in the 2nd volume of Doughty's Travels in Arabia Deserta.

MEDINA, a village of Orleans county, in north-west New
York, U.S.A., about 40 m. N.E. of Buffalo, and on Oak Orchard Creek.
Pop. (1900), 4716, (857 foreign-born); (1905, state census), 5114;
(1910) 5683. It is served by the New York Central & Hudson
River railroad, by the Buffalo, Lockport & Rochester (inter-
urban) railway, and by the Erie Canal. On Oak Orchard Creek
and near the city are electric power plants, at the Medina Falls
and at a large storage dam (60 ft. high) for water power, built
in 1902. In the neighbourhood are extensive apple, peach and pear
orchards; and vegetables, especially beans, are grown. There
are valuable quarries of Medina sandstone, a good building-
stone, quarried by the Medina Sandstone Co. In the vicinity is a
colony of Jews. The red, brownish
paving-stone, richly
decorated (hash), and the limestone of Medina are widely used.

MEDINA SIDONIA, DON ALONSO PEREZ DE GUZMAN EL
BUENO, 7TH DUKE OF (1530–1613), the commander-in-chief of
the Spanish Armada, was born on the 10th of September 1530.
He was the son of Don Juan Carlos de Guzman, eldest son of
the 6th duke, and of his wife Doña Leonor Manrique de Zúñiga y
Sotomayor. His father died in 1555, and Don Alonso became
duke, and master of one of the greatest fortunes in Europe, on
the death of his grandfather in 1530. The family of Guzman
was originally lords of Abiados, on the southern slope of the
Picos de Europa in the hill country of Leon. The name is believed to be a contraction or corruption of Gundamaris, i.e.
son of Gundamar. An early family tradition represents them as
having come from Britain, and they may have descended from
one Gundamar who lived in the north of Spain in the 10th century.
It is in the 10th century that they first appear, and they grew great
by the reconquest of the country from the Mahommades. The branch
to which the dukes of Medina Sidonia belonged was founded by Alonso Perez de Guzman (1256–1309),
known El Bueno, the good, in the sense of good at need, or stout-hearted. In 1296 he defended the
town of Tarifa on behalf of Sancho IV., and when the
bishops threatened to murder one of his sons whom they held as
a prisoner if he did not surrender, he allowed the boy to be killed.
He was rewarded by great grants of crown land. The duchy
of Medina Sidonia, the fourth largest in Spain, was conferred by John II.
in 1445 on one of his descendants, Juan Alonso de Guzman, count
of Niebla. The addition "El Bueno" to the family name
of Guzman was used by several of the house, which included many
statesmen, generals and colonial viceroys. The 7th
duke was betrothed in 1565 to Ana de Silva y Mendoza, who was
then four years of age, the daughter of the prince of Eboii.
In 1572 when the duchess was a little more than ten years of age,
the pope granted a dispensation for the consummation of the
marriage. The scandal of the time, for which there appears to be
no foundling, accused Philip II. of a love intrigue with the
princess of Eboii. The unvarying and unmerited favour he
showed the duke has been accounted for on the ground that he

1 The titles and grandeeship passed, in accordance with Castilian
law, by marriage of a daughter and heiress in 1777, to the marquess
of Villarfranca, and have since remained in that house.
MEDINA SIDONIA—MEDITERRANEAN SEA

took a paternal interest in the duchess. Don Alonso, though he bore the name of El Bueno, was a man of mean spirit. He made no serious effort to save his mother-in-law from the persecution she suffered at the hands of Philip II. His correspondence is full of whining complaints of poverty, and appeals to the king for pecuniary favours. In 1581 he was created a knight of the Golden Fleece, and was named captain-general of Lombardy. By pressing supplications to the king he got himself exempted on the ground of poverty and poor health. Yet when the marquis of Santa Cruz (q.v.) died, on the 9th of February 1585, Philip was so much moved at the loss of his favourite that he was chosen even before Santa Cruz was actually dead, and was forced to go in spite of his piteous declarations that he had neither experience nor capacity, and was always sick at sea. His conduct of the Armada justified his plea. He was even accused of showing want of personal courage, and was completely broken by the sufferings of the campaign, which turned his hair grey. The duke retained his posts of “admiral of the ocean” and captain-general of Andalusia in spite of the contempt openly expressed for him by the whole nation. When an English and Dutch armament assailed Cadiz in 1596 his sloth and timidity were largely responsible for the loss of the place. He was held up to ridicule by Cervantes in a sonnet. Yet the royal favour continued unabated even under the successor of Philip II. In 1606 the obstinacy and folly of the duke caused the loss of a squadron which was destroyed near Gibraltar by the Dutch. He died in 1615.

See Cesario Duro, La ArmadA invincible (Madrid, 1884), which gives numerous references to authorities.

MEDINA SIDONIA, or MEDIASDIONIA, a town of southern Spain, in the province of Cadiz, 21 m. by road E.S.E. of Cadiz. Pop. (1867), 11,040. Medina Sidonia is built on an isolated hill surrounded by a cultivated plain. It contains a fine Gothic church, several convents, and the ancestral palace of the dukes of Medina Sidonia. It has a small agricultural trade, chiefly in wheat, olives and oats.

Medina Sidonia has been identified by some with the Asido of Pliny, but this is uncertain. Under the Visigoths the place was erected into a bishopric (Assidonia), and attained some importance; in the beginning of the 8th century it was taken by Tariq. In the time of Idrisi (12th century) the province of Shinona or Shinoda included, among other towns, Seville and Carmona; later Arab geographers place Jadhda in the province of Seville.

MEDIOLANUM, or MEDIOLANUM (mod. Milan, q.v.), an ancient city of Italy, and the most important in Gallia Transpadana. Livy attributes its foundation to the Galli Insubes after Bellovesus after their defeat of the Etruscan, in the time of the older Tarquin. According to other authorities, the Etruscan city of Melpum which preceded it was destroyed in 396 B.C. Objects of the Bronze age have been found outside the city on the south. The name itself is Celtic. The Romans defeated the Insubes in 225–222 B.C., and restored Mediolanum itself in the latter year. Its inhabitants rebelled some twenty years later in the Hannibalic War, but were defeated and finally reduced to obedience in 156 B.C. They probably acquired Latin rights in 80, and full civic rights in 49 B.C., as did those of the other towns of Gallia Transpadana. It appears later on (but not before the 2nd century a.d.) to have become a colony. It acquired a certain amount of literary eminence, for we hear of youths going from Comum to Mediolanum to study. In Strabo’s time it was on an equality with Verona, but smaller than Pavia, but in the later times of the empire its importance increased. At the end of the 3rd century it became the seat of the governor of Aemilia and Liguria (which then included Gallia Transpadana also, thus consisting of the 9th and 11th regions of Augustus), and at the end of the 4th, of the governor of Liguria only, Aemilia having one of its own thenceforth. From Diocletian’s time onwards the praefectus praetorio and the imperial vicar of Italy also had their seat here; and it became one of the principal mints of the empire. The emperors of the West resided at Mediolanum during the 4th century, until Honorius preferred Ravenna, and in 402 transferred his court there. Its importance, described in the poems of Ausonius, is demonstrated by its many inscriptions, and the interest and variety of its contents. In these the rarity of the mention of its chief magistrates is surprising: and it is not impossible that owing to its very importance the right of appointing them had been taken from it (as Mommsen thinks). The case of Ravenna is not dissimilar. The inscriptions indicate a strong Celtic character in the population. Procopius speaks of it as the first city of the West, after Rome, and says that when it was captured by the Goths in 539, Pop. (1900), 11,040. In any case the inhabitants were killed. It was an important centre of traffic, from which roads radiated in several directions—as railways do to-day—to Comum, to the foot of the Lacus Verbanus (Lago Maggiore), to Novaria and Vercellae, to Ticinum, to Laus Pompeia and thence to Placentia and Cremona, and to Bergomum. None of these roads had an individual name, so far as we know. To its secular power corresponds the independent position which its Church took in the time of St Ambrose (q.v.), bishop of Milan in 374–397, who founded the church which bears his name, and here baptized St Augustine in a.d. 400. The latter, according to his history, were surrounded by the Goths, and later took the town, after a brave resistance. Uraia destroyed the whole of Milan in 539; and hence it is that this city, once so important a centre of Roman civilization, possesses so few remains of antiquity. Narses, in his campaigns against the Goths, had invited the Lombards to his aid. They came in a body under Alboin, their king, in 568, and were soon masters of north Italy. They entered Milan in the next year, but Pavia became the Lombard capital.

Of Roman remains little is to be seen above ground, but a portico of sixteen Corinthian columns near S. Lorenzo, which may belong to the baths of Hercules, mentioned by Ausonius, or to the palace of Maximian. Close to the Torre Sforzesco, and below remains of an ancient bridge and (possibly) of the walls of Maximian were found: and many remains of ancient buildings, including a theatre, have been discovered below ground-level. The objects found are preserved in the archaeological museum in the Castello Sforzesco. (See MILAN.)

Th. Mommsen in Corp. Inscrip. Latin. (Berlin, 1883), v. 617 sqq. (with full bibliography); Notizie degli Scavi, passim.

(T. As.)

MEDITERRANEAN SEA. The Mediterranean is all that remains of a great ocean which at an early geological epoch, before the formation of the Atlantic, encircled more than half the globe along a line of latitude. This ocean, already diminished in area, retreated after Oligocene times from the Iranian plateau, Turkestan, Asia Minor and the region of the north-west Alps. Next the plains of eastern Europe were lost, then the Aralo-Caspian region, southern Russia and finally the valley of the Danube. The “Mediterranean region,” as a geographical unit, includes all this area; the Black Sea and the Sea of Marmora are within its submerged portion, and the climate of the whole is controlled by the oceanic influences of the Mediterranean deep. Professor Sues, to whom the above description is due, finds that the Mediterranean forms no exception to the rule in according no evidence of elevation or depression within historic times; but it is noteworthy that its present basin is remarkable in Europe for its volcanic and seismic activity. Submarine earthquakes are in some parts sufficiently frequent and violent as seriously to interfere with the working of telegraph cables. Sues divides the Mediterranean basin into four physical regions, which afford probably the best means of description: (1) The western Mediterranean, from Gibraltar to Malta and Sicily,
MEDITERRANEAN SEA

enclosed by the Apennines, the mountains of northern Africa, and of southern and south-eastern Spain (Cordillère bétique). (2) The Adriatic, occupying the space between the Apennines and the Dinaric group (Suehs compares the Adriatic to the valley of the Brahmaputra). (3) A part surrounded by the fragments of the Dinaro-Taurus arch, especially by Crete and Cyprus. This includes the Aegean and the Black Sea, and its margin skirts the south coast of Asia Minor. These three parts belong strictly to Eurasia. (4) Part of the coastal region of Indo-Africa, terraced downwards in successive horizontal planes from the Slot, reaching the sea in the Little Syrt and continuing to the southern depressions of Syria. Malta and Gozo are the only islands of the Mediterranean which can be associated with this section, and, per contra, the mountain chain of north-west Africa belongs to Eurasia. Murray (1888) estimates the total area of the Mediterranean at 813,000 sq. m. Karsten (1894) breaks it up into parts as follows:

<table>
<thead>

</table>

Kümmel gives the total volume of the basin as 4,249,020 cubic kilometres or 1,019,400 cubic statute miles, and the mean depth as 1,290 fathoms. (See Ocean.)

Meteorology.—As already stated, the "Mediterranean region" forms a distinct climatic unit, chiefly due to the formation and exposition of the Mediterranean Sea. The prevailing winds in this region, which the sea traverses longitudinally, are westerly, but the sea itself causes the formation of bands of low barometric pressure during the winter season, within which cyclonic disturbances frequently develop, while in summer the region comes under the influence of the polar margin of the tropical high pressure belt. Hence the Mediterranean region characteristically has one of winter rains, the distinctive feature being more sharply defined from south to north, and the amount of total annual fall increasing in the same direction. The climate becomes more continental in type from west to east, but the local irregularities—the elevated plateaux of Algeria and Spain cause a rise of pressure in winter and delay the rainy seasons; the rains set in earlier in the west than in the east, and the total fall is greater. The driest months are January and February, and this is exaggerated in the eastern region by local land winds, which replace the cool sea-breezes of summer: overcoats are ordinarily worn in Spain and Italy till July, and are then put aside till October. Local winds form an important feature in nearly all the coast climates of the Mediterranean, especially in winter, where they are primarily caused by the rapid change of temperature from land to sea. Their occurrence, together with the weak Alderney and Great Western currents, produces great violence, occur in the Rhone valley (the Mistral), in Istria, and Dalmatia (the Bora), and in the northern Caucasus. In summer a north-west trade wind, the Maestra, occurs in the Adriatic. A similar feature is a combination of the westerly and the winter monsoon; in the Adriatic it is usually accompanied by cloud and moisture, often by rain. In Sicily and southern Italy the Sirocco occurs at all seasons; it is a dry, dusty wind from south-east or south-west. The dust is chiefly of local origin, but part comes from the Sahara. Similar winds are met with in Spain (the Leveche), but they reach their greatest development in the Siroomos of Algeria and Syria, and the Khamsin of Egypt.

Temperature.—The mean surface temperature of the waters of the Mediterranean falls from south-east, where it is over 70° F., to north-west, the average at the coast of the Gulf of Lyons being 63°. In the Gulf of Genoa the surface water of the Gulf of Lion is lighter and colder than in the Gulf of Genoa, and thence by the Strait of Messina to the Gulf of Corinth. A similar distribution is found 100 fathoms from the surface, temperature falling from 66° to 57° within 55° east of Gibraltar. At a depth of 200 fathoms the temperature falls in the Gulf of Lion, but below 250 fathoms temperatures are practically uniform to the bottom, 55° in the western basin and 56° in the eastern. The basin has expressed the observed in the Pola Deep was 63°.

Salinity.—In the extreme west the salinity of the surface water is about 35-3 per mille, and it increases eastwards to 37-6 east of Sardinia and 39-0 and upwards in the Levant. Observations of salinity in the depths of the western Mediterranean are very deficient, but the average is probably between 38-0 and 38-5. In the eastern basin the Pola expedition observed salinities of 38-7 to 39-0 to the east of a line joining Cape Matapan with Alexandria, and 38-2 to 39-0 west of this. The saltier waters apparently tend to make their way westwards close to the African coast, and at the bottom the highest salinities have been observed south of Crete. Etmitchtzi states that the saltiest water of the whole basin occurs in the Aegean Sea.

Circulation.—There is little definite circulation of water within the Mediterranean itself. In the straits joining it with the Atlantic and Black Sea the fresher surface waters flow inwards to assist in making good the loss by evaporation at the surface of the Mediterranean, and in both cases dense water makes its way outwards along the bottom of the channels, the currents being less in volume and delivery than the inflowing. Elsewhere local surface currents are developed, either drifts due to the direct action of the winds, or streams produced by wind action in the straits. In the Adriatic the currents are moderately strong, and possibly at times have caused the development of a distinct current system, although they are often sufficient to obliterate the feebly tidal action characteristic of the Mediterranean. Dr Natterer, the chemist of the Pola expedition, has expressed the belief that the pelagic fauna is solely due to the want of circulation in the depths.
DEPOSITS.—A great part of the bottom of the Mediterranean is covered with blue mud, frequently with a yellow upper layer containing a considerable proportion of carbonate of lime, chiefly shells of pelagic Foraminifera. In many parts, particularly in the eastern basin, a calcareous ooze about a foot to three inches in thickness, is met with; and Natterer suggested that the formation of this crust may be due to the production of carbonate of lime by the organisms of the nature are undergoing oxidation, and the consequent precipitation of carbonate of lime and other substances from the waters nearer the surface. This view, however, has not met with general acceptance.

MEDIUM, primarily a person through whom, as an intermediary, communication is deemed to be carried on between living men and spirits of the departed, according to the spiritualistic hypothesis; such a person is better termed sensitive or automatist. The phenomena of mediumship fall into two classes, (1) "physical phenomena" (q.v.) and (2) trance and automatic phenomena (utterances, script, &c.); both these may be manifested by the same person, as in the case of D. D. Home and Stainton Moses, but are often independent.

I. No sufficient mass of observations is to hand to enable us to distinguish between the results of trickery or hallucination on the one hand, and genuine supernatural phenomena on the other; but the evidence for raps and lights is good; competent observers have witnessed supposed materializations and there is respectable evidence for movements of objects.

Mediumship in the modern sense of the term may be said to have originated with the Rochester rappings of 1848 (see Spiritualism); but similar phenomena had been reported by such authors as Apollonius of Tyana; they figure frequently in the lives of the saints; and the magician in the lower stages of culture is in many respects a counterpart of the white medium. Among physical mediums who have attained celebrity may be mentioned D. D. Home (q.v.), Stainton Moses and Eusapia Palladino; the last has admittedly been fraudulent at times, but no deceit was ever proved of Home; Stainton Moses sat in a private circle and no suspicion of his good faith was ever aroused.

W. Stainton Moses (1839-1892) was a man of university education, a clergyman and a schoolmaster. In 1857 he became interested in spiritualism and soon began to manifest mediumistic phenomena, which continued for some ten years. These included, besides trance communications, raps, telekinesis, levitation, production of lights, perfumes and musical sounds, apparitions and materialized hands. But the conditions under which the experiments were tried were not sufficiently rigid to exclude the possibility of normal causes being at work; for no amount of evidence that the normal life is marked by no lapse from rectitude affords a presumption that uprightness will characterize states of secondary personality.

Eusapia Palladino has been observed by Sir O. Lodge, Professor Richet, F. W. H. Myers, and other eminent investigators; the first named reported that none of the phenomena in his presence went beyond what could be accomplished in a normal manner by a free and unconquered person; but he was convinced that movements were produced without apparent contact.

Among other phenomena ascertained to characterize the mediumship of Eusapia are the production of temporary prolongations from the medium's body; these have been seen in a good light by competent witnesses. It was shown in some sittings held at Cambridge in 1895 that Eusapia produced phenomena by fraudulent means: but though the evidence of this is conclusive it has not been shown that her mediumship is entirely fraudulent. Automatic records of seances can alone solve the problems raised by physical mediumship. It has been shown in the Davey-Hodgson experiments that converse observation, even for a short period, is not reliable, and that in the processing of the observations many omissions and errors are inevitable. Even were it otherwise, no care could provide against the possibility of hallucination.

II. The genuineness of trance mediumship can no longer be called in question. The problem for solution is the source of the information. The best observed case is that of Mrs Piper of Boston; at the outset of her career, in 1854, she did not differ from the ordinary American trance medium. In 1883 the attention of Professor William James of Harvard was attracted to her; and for twenty years she remained under the supervision of the Society for Psychical Research. During that period three phases may be distinguished: (1) 1884-1891, trance utterances of a "control" calling himself Dr Phinuit, a French physician, of whose existence in the body no trace can be found; (2) 1892-1896, automatic writing by a "control" known as "George Pelham," the pseudonym of a young American author; (3) 1896 onwards, supervision by "controls" purporting to be identical with those associated with Stainton Moses. There is no evidence of regarding Mrs Piper as anything but absolutely honest. Much of the material remains unpublished, partly on account of its intimate character. Many of those to whom the communications were made have been convinced that the "controls" are none other than discarnate spirits. Probably no absolute proof of identity can be given, though the reading of sealed letters would come near it; these have been left by more than one prominent psychical researcher, but so far the "controls" who claim to be the writers of them have failed to give their contents, even approximately.

Professor Flournoy has investigated a medium of very different. nature, as the late Eusapia Palladino is known as Madame Gauthier; her good faith nothing but her phenomena—trance utterance and glossolalia—have undoubtedly been produced by her own mind. These represent her to be the reincarnation of a Hindu princess, and of Marie Antoinette among others, but no evidence of identity has been produced. The most striking phenomenon of her trance was the so-called Martian language, eventually shown by analysis to be a derivative of French, comparable to the languages invented by children in the nursery, but more elaborate.

Podmore, Modern Spiritualism; the Proceedings and Journal of the Society for Psychical Research, passim; for a convenient survey of the Piper case, see: F. Sage, Madame Piper; J. Maxwell, Les Phénomènes psychiques (1903; Eng. trans., 1905); Th. Flournoy, Des Indes à la planète Mars, For fraudulent methods, see Confessions of a Medium (London, 1882); Truesdell, Bottom Facts of Spiritualism, and works cited by Myers, II., 592-593. (N. W. T.)

MEDJIDE, or MEJIDE, the name of a military and knightly order of the Turkish Empire, and also of a silver Turkish coin, worth twenty piastres. The coin was first struck in 1844, and is still in circulation in 1872 by Sultan Abdul Medjid, whose name was therefore given to them. (See KNIGHTHOOD AND CHIVALRY: § Orders of Knighthood.)

MEDLAR, Mespilus germanica, a tree of the tribe Pomeae of the order Rosaceae, closely allied to the genus Pyrus, in which it is sometimes included; it is a native of European woods, &c., from Holland southwards, and of western Asia. It occurs in hedges, &c., in middle and south England, as a small, much-branched, deciduous, spiny tree, but is not indigenous. The medlar was well known to the ancients. Pickering (Chron. Hist. Pl. p. 201) identifies it with a tree mentioned in a Shao-yin ode (She-King, ii. 1, 2, 827 b.c). It is theâymdh of Theophrastus and Mespilus of Pliny. The Latin mespilus or mespilium became in Old French mesle or medle, "the fruit," meslier, medlier, "the tree." The modern French nèfle is from a corruption nespilum of the Latin. The German Mispel preserves the original more closely. The well-known fruit is globular, but depressed above, with leafy persistent sepals, and contains stones of a hemispherical shape. It is not fit to eat until it begins to decay and becomes "bledted," when it has an agreeable acid and somewhat astrin- gent flavour. Several varieties are known in cultivation. The large Dutch medlar, which is very widely cultivated, is a naturally crooked growths, the larger, much-fattened fruit is inferior in quality to the Nottingham, which is a tree of upright habit with fruits of about 1 in. diameter, superior to any other variety. There is also a stoneless variety with still smaller fruits, but the quality is not so good.

The medlar is propagated by budding or grafting upon the white-thorn, which is most suitable if the soil is dry and sandy, or on the quince if the soil is moist; the pear stock also succeeds
MÉDOC—MEDUSA

well on ordinary soils. It produces the best fruit in rich, loamy, somewhat moist ground. The tree may be grown as a standard, and chiefly requires pruning to prevent the branches from rubbing each other. The fruit should be gathered in November, on a dry day, and laid out upon shelves. It becomes "bitten" and fit for use in two or three weeks. The Japanese medlar is *Eriobotrya japonica* (see LOQUAT), a genus of the same tribe of Rosaceae.

MÉDOC, a district in France adjoining the left bank of the Gironde from Blanquefort (N. of Bordeaux) to the mouth of the Gironde. Its length is about 50 m., its breadth averages between 6 and 7 m. It is formed by a number of low hills, which separate the Landes from the Gironde, and is traversed only by small streams; the Gironde itself is muddy, and often enveloped in fog, and the region as a whole is far from picturesque. Large areas of its soil are occupied by vineyards, the products of which form the finest growths of Bordeaux.

(See WINE.)

MEDUSA, the name given by zoologists to the familiar marine animals known popularly as jelly-fishes; or, to be more accurate, to those jelly-fishes in which the form of the body resembles that of an umbrella, bell or parachute. The name medusa is suggested by the tentacles, usually long and often numerous, implanted on the edge of the umbrella and bear the stinging organs of which sea-bathers are often disagreeably aware. The tentacles serve for the capture of prey and are very contractile, being drawn into a tube or, as it is termed, retracted and forming corkscrew-like curls. Hence the animals have suggested to vivid imaginations the head of the fabled Gorgon or Medusa with her *chevelure* of withering snakes.

The medusa occurs as one type of individual in the class Hydrozoa (q.v.), the other type being the polyp (q.v.). In a typical medusa we can distinguish the following parts. The umbrella-like body bears a circle of tentacles at the edge, whereby the body can be divided into a convex *exumbrella* or exumbrellal surface and a concave *subumbrella* or subumbrellal surface. The vast majority of jelly-fishes, especially Crustacea, are suspended from the exumbrella upwards, the subumbrella downwards. A few species, however, attach themselves temporarily or permanently to some firm object by the exumbrellal surface of the body, and then the subumbrellal surface is directed upwards. From the centre of the subumbrellal surface hangs down the *manubrium*, like the handle of an umbrella or the clapper of a bell, bearing the mouth at its extremity. In addition to the tentacles, the margin of the umbrella bears sense-organs, which may be of several kinds and may attain a high degree of complexity. Medusae capture their prey, consisting of small organisms of various kinds, especially Crustacea, by means of the tentacles which hang out like fishing-lines in all directions. When the prey comes into contact with the tentacles it is paralyzed, and at the same time held firmly, by the barbed threads shot out from the stinging organs or nematocysts. Then by contraction of the tentacles the prey is drawn into the mouth. Medusae thus form an important constituent of the plankton or floating fauna of the ocean, and compete with fish and other animals for the food-supply furnished by minuter forms of life.

A medusa has a layer of muscles, more or less strongly developed, running in a circular direction on the surface of the subumbrella, the contractions of which are antagonized by the elasticity of the gelatinous substance of the body. By the contraction of the subumbrellar circular muscles the concavity of the subumbrella is increased, and as water is thereby forced out of the subumbrellar cavity the animal is jerked upwards. In this way jelly-fish progress feebly by the pumping movements of the umbrella. Besides the circular subumbrellar muscles, there may be others running in a radial direction, chiefly developed as the longitudinal retractor muscles of the manubrium. In some cases the circular subumbrellar muscles form a rim known as the *velum* (q.v., see fig. 1), projecting into the subumbrellar cavity just within the ring of marginal tentacles. The two principal divisions of the medusae are characterized by the presence or absence of a velum.

Correlated with the well-developed muscular system and sense-organs of the medusa, we find also a distinct nervous system, either, when there is no velum, in the form of concentrations of nervous matter in the vicinity of each sense-organ, or, when a velum is present, as two continuous rings running round the margin of the umbrella, one external to the velum (exumbrellar nerve-ring, *n.r.* 1, see fig. 1), the other internal to it (subumbrellar nerve-ring, *n.r.* 2). The exumbrellar nerve-ring is the larger and supplies the tentacles; the subumbrellar ring supplies the velum.

Every possible variety of body-form compatible with the foregoing description may be exhibited by different species of medusae. The bell may show any form which can be compared to a shallow saucer, a cup, a bell or a saucer-like umbrella, the marginal tentacles may be very numerous or may be few in number or even absent altogether; and they may be simple filaments, or branched in a complicated manner. The manubrium may be excessively long or very short, and in rare cases absent, the mouth then being flush with the subumbrellar surface. The mouth may be circular or four-cornered, and in the latter case the manubrium at the angles of the mouth may become drawn out into four lappets, the oral arms, each with a groove on its inner side continuous with the corner of the mouth. The oral arms are the starting-point of a further series of variations; they may be simple flaps, crinkled and folded in various ways, or they may be subdivided, and then the branches may simulate tentacles in appearance. In the genus *Rhizostoma*, common on the British coasts and conspicuous on account of its large size, the oral arms, originally distinct and four in number, undergo concentric growth, so that the entrance to the mouth is reduced to numerous fine pores and canals.

Like the external structure, the internal anatomy of the medusa shows a complete radial symmetry, and is simple in plan but often complicated in detail (see fig. 1). As in all Hydrozoa (q.v.) the body wall is composed of two cell-layers, the ectoderm and endoderm. Between which is a structureless gelatinous secreted layer, the mesogloea. As the name jelly-fish implies, the mesogloea is greatly developed and abdomen quality for processes of the cells of the ectoderm and endoderm, or it may contain cells which have migrated into it from these two layers. The ectoderm covers the whole external surface of the animal, while the endoderm lines the coelenteron or gastrovascular space; the two layers meet each other, and become continuous, at the edge of the mouth. The mouth leads at once into the true digestive cavity, divisible into an oesophageal region in the manubrium and a more dilated cavity, the stomach (*s.l*), occupying the centre of the umbrella. From the stomach, canals arise termed the radial canals (*r.c.*); typically four in number, they run in a radial direction to the edge of

---

1 For other variations of the medusa, often of importance for systematic classification, see HYDROMEDUSAE and SCYPHOMEDUSAE.
of the umbrella. There the radial canals are joined by a ring-canal (C.) which runs round the margin of the umbrella. From the ring-canal are given off tentacle-canals which run down the axis of each tentacle; in many cases, however, the cavity of the tentacle is obliterated and instead of a canal the tentacle contains a ring of ciliated tentacle-ends. As the gassters approach the mouth, the ring-canal and tentacle-canals, constitute together the gastrovascular system and are lined throughout by endoderm, which forms its floor. It is supplied by its subumbrellar surface, its tentacle, and ring canal together as a web; this is the so-called endodermallamella (e.). a most important feature of medusan morphology, the nature of which will be apparent when the development is described. As a general rule, a basement of mesogloea may become elaborated into eye-like structures with lens, retina and vitreous body; (2) organs of the sense of balance or orientation, commonly termed otocysts or statocysts. The sense-organs are always situated at the margin of the umbrella and may be distinguished from the morphological point of view into two categories, as the one they are, or are not, derived from modifications of tentacles; in the former case they are termed endotendrils. (For fuller information upon the sense-organs see HYDROMEDUSAE.)

MEDWAY—MEEK

MEDWAY, a river in the south-east of England. It rises in the Forest Ridges, S.W. of East Grinstead in Sussex, and, increased by many feeders from these picturesque hills, has an easterly course to the county boundary, which it forms, turning northward for a short distance. Entering Kent near Ashurt, its course becomes north-easterly, and this direction is generally maintained to the mouth. The river passes Tonbridge, receiving the Eden from the west, and later the Tese and Beult from the south-west, all these being eastwards flowing, and reaching to the south of the North Downs. These hills are breached by the Medway in a beautiful valley, in which lies Maidstone, generally much narrower than the upper valley. The characteristic structure of this part of the valley is considered under the heading Downs. Below Maidstone the valley forms a perfect basin, the hills descending upon it closely above Rochester. Below this city the river enters a broad, winding estuary, passing Chatham, and at Sheerness joining that of the Thames, so that the Medway may be considered a tributary, and its drainage area of 680 sq. m. reckoned as part of that of the greater river.

Stems, the length of the Medway is about 60 m., excluding its many lesser windings. The estuary is navigable for sea-going vessels drawing 24 ft. up to Rochester Bridge. A considerable traffic is carried on by small vessels up to Maidstone, and by barges up to Tonbridge, the total length of the navigation being 43 m. The marshy lowlands along the course of the river have yielded extensive remains of Roman pottery, a plain ware of dark slate-colour.

MEANEER, or MIAIR, a village in Sind, India, on the Indus 6 m. N. of Hyderabad. Pop. (1901), 962. It is famous as the scene of the battle in which Charles Napier, with only 2,000 and the native force of 20,000, was defeated by the native force of 20,000. The battle took place on 17th Feb. 1843. The result of this victory was the conquest and annexation of Sind.

MEEK, FIELDING BRADFORD (1817-1876), American geologist and palaeontologist, the son of a lawyer, was born at Madison, Indiana, on the 10th of December 1817. In early life he was in business as a merchant, but his leisure hours were devoted to collecting fossils and studying the rocks of the neighbourhood of Madison. Being unsuccessful in business he turned his whole attention to science, and in 1838 he gained employment under Mr. John Allen, of Iowa, Wisconsin and Minnesota. In 1852 he became assistant to Professor James Hall at Albany, and worked at palaeontology with him until 1858. Meanwhile in 1853 he accompanied Dr. F. V. Hayden in an exploration of the "Bad Lands" of Dakota, and brought back valuable collections of fossils. In 1858 he went to Washington, where he devoted his time to the palaeontological work of the United States Geological and geographical surveys, his work bearing "the stamp of the most faithful and conscientious research," and raising him to the highest rank as a palaeontologist. Besides many separate contributions to science, he prepared with W. M. Gailb (1839-1878), two volumes on the palaeontology of California (1864-1866); and also a Report on the Invertebrate Cretaceous and Tertiary Fossils of the Upper Missouri Country (1876). He died at Washington, on the 22nd of December 1876.
MEER—MEERSCHAUM

MEER, JAN VAN DER (1621–1679), more often called Vermeer of Delft—not to be confounded with the elder (1628–
1691) or younger (1669–1705) Van der Meer of Haarlem, or with Van der Meer of Utrecht—is one of the excellent Dutch painters
about whom the Dutch biographers give us little information.1 Van der Meer, or Vermeer, was born in Delft, and was a pupil of Carel Fabritius, whose junior he was by only eight years. The works by Fabritius are few, but contemporaries speak of him as a man of remarkable power, and the paintings now ascertained to be from his hand, and formerly ascribed to Rem-
brandt, prove him to have been deeply imbued with the spirit and manner of that master. Whether Van der Meer had ever
any closer relation to Rembrandt than through companionship with Fabritius remains uncertain. In 1653 he married Catherine
Bolens, and in the same year he entered the gild of St Luke of
Delft, becoming one of the heads of the gild in 1661 and again in 1670. He died at Delft in 1675, leaving a widow and eight
children. His circumstances cannot have been flourishing, for
at his death he left twenty-six pictures undisposed of, and his widow had to apply to the court of insolvency to be placed under
a tutor, a woman who was Leuwenhoek, the naturalist.

For more than two centuries Van der Meer was almost com-
pletely forgotten, and his pictures were sold under the names
and forged signatures of the more popular De Hooch, Metsu,
Ter Borch, and even of Rembrandt. The attention of the
art-world was first recalled to this most original painter by Thoré,
an exiled Frenchman, who described his then known works in
Musées de la Hollande (1858–1860), published under the assumed
name of W. Burger. The result of his researches continued in
his Galerie Swermondt and Galerie d'Armen, was afterwards
given by him in a charming, though incomplete, monograph
(Gazette des beaux-arts, 1866, pp. 297, 458, 542). The task was
prosecuted with success by Havard (Les Artistes hollandais,
and by Obreen (Nederlandsche Kunstgeschiedenis, D. iv.), and
we are now in a position to refer to Van der Meer's works. His
pictures are rarely dated, but one of the most important, in
the Dresden Gallery, bears the date 1650, and thus gives us a
key to his styles. With the exception of the "Christ with
Martha and Mary" in the Coats collection at Glasgow, it is
perhaps the only one, hitherto recognized, that has figures of
life size, though his authorship is claimed for several others.
The Dresden picture of a "Woman and Soldier," with only
figures, is painted with remarkable power and boldness, with
great command over the resources of colour, and with
wonderful expression of life. For strength and colour it more
than holds its own beside the neighbouring Rembrandts. To this early
period of his career belong, from internal evidence, the "Reading
Girl" (now in a date gallery, the important historical and master-
"Woman of Dresden") in the museum of the Hague, the "Milk-Woman"
and the small street view, both identified with the Six collection
at Amsterdam, the former now in the Rijksmuseum; the magnifi-
cent "The Letter" also at Amsterdam, "Diana and the Nymphs"
(formerly ascribed to Vermeer of Utrecht) at the Hague Gallery,
and others. In all these we find the same brilliant style and
vigorous work, a solid impasto, and a crisp, sparkling touch.
His first manner seems to have been influenced by the plein
air style of the rembrandted Rembrandts, and also of Duykens
in Holland in the last quarter of the century. During the final
ten or twelve years of his life Van der Meer adopted a second
manner. We now find his painting smooth and thin, and his
colours paler and softer. Instead of masculine vigour we have
refined delicacy and subtlety, but in both styles beauty of tone
and perfect harmony are conspicuous. Through all his work
may be traced his love of lemon-yellow and of blue of all shades.
Of his second style typical examples are to be seen in "The
Coquette" of the Branswick Gallery, in the "Woman Reading"
in the Van der Hoop collection now at the Rijksmuseum at
Amsterdam, in the "Lady at a Casement" belonging to Lord
Powerscourt (exhibited at the Royal Academy, 1876) and in
the "Music Master and Pupil" belonging to the King (exhibited
at the Royal Academy, 1876).

Van der Meer's authentic pictures in public and private
collections amount to about thirty. There is but one in the
Louvre, the "Lace Maker"; Dresden has the two afore-
mentioned, while Berlin has three, all acquired in the Swermond
collection, and the Czernin Gallery of Vienna is fortunate in
possessing a fine picture, believed to represent the artist in his
studio. In the Arenberg Gallery at Brussels there is a remark-
able head of a girl, half the size of life, which seems to be inter-
between between his two styles. Several of his paintings are
in private foreign collections.

In all his work there is a singular completeness and charm.
His tone is usually silvery with nearly golden, and the lighting of his interiors is equal and
natural. In all cases his figures seem to move in light and air,
and in this respect he resembles greatly his fellow-worker De
Hooch. It is curious to read that, at one of the auctions in
Amsterdam about the middle of the 18th century, a De Hooch
is praised as being "nearly equal to the famous Van der Meer of
Delft."

In the Delft Museum at the Hague, in the Rijksmuseum
at Amsterdam, and in the Czernin Gallery at Vienna are found
a few of his pictures and drawings of the 17th century, but with
a few exceptions these are all of the "second" style, that is
early 18th century, and are usually unsigned.

MEERSCHAUM

MEERANE, a town in the kingdom of Saxony, 9 m. N.
of Zwickau and 37 S. of Leipzig by rail. Pop. (1905),
26,005. It contains a fine medieval church (Evangelical).
It is one of the most important woollen industrial centres of Germany for the manufacture
of woollen and mixed cloths, and in these products has a large
export trade, especially to America and the Far East. There
are also extensive dyeworks, tanneries and machine factories.

See Leopold, Chronik und Beschreibung der Fabrik- und
Handelsstadt Meerane (1863).

MEERSCHAUM. German word designating a soft white
mineral sometimes found floating on the Black Sea, and rather
suggestive of sea-foam (Meerschaum), whence also the French
name for the same substance, écume de mer. It was termed
by E. F. Glocker sepilite, in allusion to its remote resemblance
to the "bone" of the sepa or cuttle-fish. Meerschaum is
an opaque mineral of white, grey or cream colour, breaking
with a conchoidal or fine earthy fracture, and occasionally
though rarely, fibrous in texture. It can be readily scratched
with the nail, its hardness being about 2. The specific gravity
varies from 0.968 to 1.179, but the porosity of the mineral may
lead to error. Meerschaum is a hydrous magnesium silicate,
with the formula Mg[SiO4]2, or MgSiO3·H2O.

Most of the meerschaum of commerce is obtained from Asia
Minor, chiefly from the plain of Eskî-Shehr, on the Haidar
Pasha-Angora railway, where it occurs in irregular nodular
masses, in alluvial deposits, which are extensively worked
for its extraction. It is said that in this district there are 4000
shafts leading to horizontal galleries for extraction of the
meerschaum. The principal workings are at Sępcej-Łodzha
and Kemikdji-Łodzha, about 80 m. S.E. of Eskî-Shehr. The
mineral is associated with magnesite (magnesium carbonate),
the primitive source of both minerals being a serpentine. When
first extracted the meerschaum is soft, but it hardens on exposure
to solar heat or when dried in a warm room. Meerschaum
is found also, though less abundantly, in Greece, as at Thebes,
and in the islands of Euboea and Samos; it occurs also in
serpentine at Hrubieszitz near Kromau in Moravia. It is found
in a limited extent at certain localities in France and Spain,
and is known in Morocco. In the United States it occurs in
extensive beds in Chester (county), Pennsylvania, and in
South Carolina and Utah.

Meerschaum has occasionally been used as a substitute for
soap and fuller's earth, and it is said also as a building material;
but its chief use is for tobacco-pipes and cigar-holders. The
natural nodules are first scraped to remove the rough earthy matrix, then dried, again scraped and polished with wax. The rudely shaped masses thus prepared are sent from the East to Vienna and other manufacturing centres, where they are turned and carved, smoothed with glass-paper and Dutch rubes, heated in wax or stearine, and finally polished with bone-ash, &c. Imitations are made in plaster of Paris and other preparations.

The soft, white, earthy mineral from Långbanshyttan, in Vormland, Sweden, known as apophite (δροσός, foam), is closely related to meschaum. It may be noted that meschaum has sometimes been called magnesite (q.v.).

MEERUT, a city, district and division of British India, in the United Provinces. The city is half-way between the Ganges and the Jumna, and has two stations on the North-Western railway, 37 m. N.E. from Delhi. Pop. (1901), 118,129. The city proper lies south of the cantonments, and although dating back to the days of the Buddhist emperor Asoka (c. 250 B.C.) Meerut owes its modern importance to its selection by the British government as the site of a great military station. In 1805 it is mentioned as “a ruined, depopulated town.”

The cantonment was established in 1806, and the population rose to 29,014 in 1847, and 82,035 in 1853. The town is an important centre of the 7th division of the northern army, with accommodation for horse and field artillery, British and native cavalry and infantry. It was here that the first outbreak of the Mutiny of 1857 took place. (See Indian Mutiny.)

The District of Meerut forms part of the upper Doab, or tract between the Ganges and the Jumna, extending from river to river. Area, 23,54 sq. m. Though well wooded in places and abundantly supplied with mango groves, it has but few patches of jungle or waste land. Sandy ridges run along the low watersheds which separate the maps in Jan but with this exception the whole district is one continuous expansion of careful and prosperous tillage. Its fertility is largely due to the system of irrigation canals. The Eastern Jumna canal runs through the whole length of the district, and supplies the rich tract between the Jumna and the Hindan with a network of distributary streams. The main branch of the Ganges canal passes across the centre of the plateau in a sweeping curve and waters the middle tract. The Anupshahr branch supplies irrigation to the Ganges slope, and the Agra canal passes through the southern corner of Loni pargana from the Hindan to the Jumna. Besides these natural and artificial channels, the country is everywhere cut up by small water-courses. The Burh Ganga, or ancient bed of the Ganges, lies at some distance from the modern stream; and on its bank stood the abandoned city of Hastinapura, the legendary capital of the Pandavas at the period of the Mahabharata, said to have been deserted many centuries before the Christian era, owing to the encroachments of the river.

The comparatively high latitude and elevated position of Meerut make it one of the healthiest districts in the plains of India. The average temperature varies from 57° F. in January to 89° in June. The rainfall is small, less than 30 in. annually. The only endemic disease in the district is malarial fever; but small-pox and cholera occasionally visit it as epidemics. The population in 1901 was 1,540,175, showing an increase of 10-6% in the decade. The principal crops are wheat, pulse, millet, sugar-cane, cotton and indigo, but this last crop has declined of late years almost to extinction. The district is traversed by the North-Western railway, and also contains Ghaziabad, the terminus of the East Indian system, whence a branch line runs to Delhi, while a branch of the Oudh & Rohilkhand railway from Moradabad to Ghaziabad was opened in 1900.

The authentic history of the district begins with the Moslem invasions. The first undoubted Mahommedan invasion was that of Kutbeddin in 1191, when Meerut town was taken and all the Hindu temples turned into mosques. In 1398 Timur captured the fort of Loni after a desperate resistance, and put all his Hindu prisoners to death. He then proceeded to Delhi, and after his memorable sack of that city returned to Meerut, captured the town, razed all the fortifications and houses of the Hindus, and put the male inhabitants to the sword. The establishment of the great Mogul dynasty in the 16th century, under Baber and his successors, gave Meerut a period of internal tranquillity and royal favour. After the death of Aurangzeb, however, it was exposed to alternate Sikh and Marhatta invasions. From 1707 till 1775 the country was the scene of perpetual strife, and was only rescued from anarchy by the exertions of the military adventurer Walter Reinhardt, afterwards the husband of the celebrated Begum Samru, who established himself at Sardhana in the north, and ruled a large estate. The southern tract, however, remained in its anarchic condition under Marhatta exactions until the fall of Delhi in 1853, when the whole of the country between the Jumna and the Ganges was ceded by Sindia to the British. It was formed into a separate district in 1818. In the British period it has become memorable for its connexion with the Mutiny of 1857.

The Division of Meerut comprises the northern portion of the Doab. It consists of the six districts of Dehra Dun, Saharanpur, Muzaffarnagar, Meerut, Bulandshahr and Aligarh. Area, 11,392 sq. m.; pop. (1901), 5,970,711, showing an increase of 10-6% over the decade. (See Meerut District Gazetteer (Allahabad, 1904).)

MEETING (from “to meet,” to come together, assemble, O. Eng. mîten; cf. Du. moeten, Swed. mûta, Goth. gamotan, &c., derivatives of the Teut. word for a meeting, seen in O. Eng. mût, moot, an assembly of the people; cf. witanagemot), a gathering together of persons for the purpose of discussion or for the transaction of business. Public meetings may be either those of statutory bodies or assemblies of persons called together for social, political or other purposes. In the case of statutory bodies, by-laws usually fix the quorum necessary to constitute a legal meeting. That of limited companies may be either by reference to the capital held, or by a fixed quorum or one in proportion to the number of shareholders. It has been held that in the case of a company it takes at least two persons to constitute a meeting (Sharp v. Dave, 1886, 2 Q.B.D. 26). In the case of public meetings for social, political or other purposes no quorum is necessary. They may be held, if they are for a lawful purpose, in any place, on any day and at any hour, provided they satisfy certain statutory provisions or by-laws made under the authority of a statute for the safety of persons attending and for the orderly conduct of business. If, however, a meeting is held in the street and it causes an obstruction those convening the meeting may be proceeded against for obstructing the highway. The control of a meeting and the subjects to be discussed are entirely within the discretion of those convening it, and whether the meeting is open to the public without payment, or subject to a charge or to membership of a specified body or society, those present are there merely by virtue of a licence of the conveners, which licence may be revoked at any time. The person whose licence is revoked may be requested to withdraw from the meeting, and on his refusal may be ejected with such force as is necessary. If he employs violence to those removing him he commits a breach of the peace for which he may be given into custody. An important English act has dealt for the first time with the disturbance of a public meeting. The Public Meeting Act 1908 enacted that any person who at a lawful public meeting acts in a disorderly manner for the purpose of preventing the transaction of the business for which the meeting was called together shall be guilty of an offence, and if the offence is committed at a political meeting held in any parliamentary constituency between the issue and return of a writ, the offence is made an illegal practice within the meaning of the Corrupt and Illegal Practices Prevention Act 1883. Any person who incites another to commit the offence is equally guilty. A public meeting is usually controlled by a chairman, who may be appointed by the conveners or elected by the meeting itself. On the chairman falls the duty of preserving order, of calling on persons to speak, deciding points of order, of putting questions to the meeting
MEGALOPOLIS

for decision, and declaring the result and other incidental matters.

In England it is illegal, by a statute of George III. (Seditious Meetings Act 1817), to hold a public meeting in the open air within 1 m. of Westminster Hall during the sitting of Parliament.

MEGALOPOLIS, an ancient city of Arcadia, Greece, situated in a plain about 20 m. S.W. of Tegea, on both banks of the Helisson, about 21 m. above its junction with the Alpheus. Like Messene, it owed its origin to the Theban general Epaminondas, and was founded in 370 B.C., the year after the battle of Leuctra, as a bulwark for the southern Arcadians against Sparta, and as the seat of the Arcadian Federal Diet, which consisted of ten thousand men. The builders were protected by a Theban force, and directed by ten native oecists (official "founders"), an attempt to reduce Megalopolis; but the Thebans sent assistance, the Megalopolitans had appealed to Athens, an appeal which gave occasion to the narration of Demosthenes, Ἱππος Μεγαλοπόλιτος. The Spartans were now obliged to conclude peace with Megalopolis and acknowledge her autonomy. Nevertheless their feeling of hostility did not cease, and Megalopolis consequently entered into friendly relations with Philip of Macedon. Twenty years later, when the Spartans and their allies rebelled against the power of Macedon, Megalopolis remained firm in its allegiance, and was subjected to a long siege. After the death of Alexander, Megalopolis was governed by native tyrants. In the war between Cassander and Polyperchon it took part with the former and was besieged by the latter. On this occasion it was able to send into the field an army of fifteen thousand.

who likewise attended to the peopling of the new city, which apparently drew inhabitants from all parts of Arcadia, but especially from the neighbouring districts of Maenalus and Parrhasia. Forty townships are mentioned by Pausanias (viii. 27, 3-5) as having been incorporated in it. It was 50 stadia in circumference, and was surrounded with strong walls. Its territory was the largest in Arcadia, extending northward 24 m. The city was built on a magnificent scale, and adorned with many handsome buildings, both public and private. Its temples contained many ancient statues brought from the towns incorporated in it. After the departure of Epaminondas, Lycomedes of Mantinea succeeded in drawing the Arcadian federation away from its alliance with Thebes, and it was consequently obliged to make common cause with Athens. An attempt on the part of the federation to use the treasures of the temple of Zeus at Olympia led to internal dissensions, so that in the battle of Mantineia (362) one half of the Arcadians fought on the side of the Spartans, the other on that of the Thebans. After this battle many of the inhabitants of Megalopolis sought to return to their former homes, and it was only by the assistance of three thousand Thebans under Pammenes that the authorities were able to prevent them from doing so. In 355, when Thebes had her hands full with the so-called Sacred War, the Spartans made

In 234 B.C. Lydiades, the last tyrant of Megalopolis, voluntarily resigned his power, and the city joined the Achaean League. In consequence of this it was again exposed to the hatred of Sparta. In 222 Cleomenes plundered it and killed or dispersed its inhabitants, but in the year following it was restored and its inhabitants reinstated by Philopoemen, a native of the city. After this, however, it gradually sank into insignificance. The only great men whom it produced were Philopoemen and Polybius the historian. Lycurgas, the father of the latter, may be accounted a third. In the time of Pausanias the city was mostly in ruins.

The site of Megalopolis was excavated by members of the British School at Athens in the years 1890-1892. The description of Pausanias is so clear that it enabled Curtius, in his Peloponnesos, to give a conjectural plan that was found to tally in most respects with the reality. The town was divided into two approximately equal parts by the river Helisson, which flows through it from east to west. The line of the walls may be traced, partly by remains, partly by the contours it must have followed, and confirms the estimate of Polybius that they had a circuit of 50 stades, or about 53 m. It is difficult to see how the river bed, now a byroad and shingly waste, was dealt with in ancient times; it must have been embanked in some way, but there are no remains to show whether the fortification wall

MEGALOPOLIS.

By permission from plans by R.W.Schulte &"A Topographical Survey of Megalopolis (Society for the Promotion of Hellenic Studies)"
was carried across the river at either end or along the parallel embankments so as to make two separate enclosures. There must have been, in all probability, a bridge to connect the two halves of the city, but the foundations seen by Leake and others, and commonly supposed to belong to such a bridge, proved to be only the substructures of the precinct of Zeus Soter. The buildings north of the river were municipal and were grouped round the square agora. One of the complete plans has been recovered, the portico of Philip, a splendid building, which bounded the agora on the north; it was 300 ft. long, with three rows of columns running its whole length, three in the outer line to each one in the two inner lines; it had a shaded colonnade at its back. When one of the lowest rows of seats of the agora was found the precinct of Zeus Soter: it consists of a square court surrounded by a double colonnade, and faced on the west side by a small temple; on the east side was an entrance or propylaeum approached by a ramp. In the midst of the court was a structure which has been variously interpreted as an altar or as the base of the great group of Zeus and Megalopolis, which is recorded to have stood here. North of this was the Stoa Myropolis, forming the east boundary of the agora, and, between this and the Stoa of Phillip, the Arched it were the foundations for an earlier wooden parvis, dates, but seem all to fit into a harmonious plan. The buildings on the south and west of the agora have been almost entirely destroyed by the Helisson and a tributary brook. On the south bank of the river were the chief federal buildings, the theatre (noted by Pausanias as the largest in Greece), and the Thersilion or parliament hall of the ten thousand Arcadians. These two buildings form part of a common design, the great portico of the Thersilion facing the orchestra of the theatre. As a consequence of this arrangement, the plan of the theatre is abnormal. The auditorium has as its lowest row of seats a set of "three" or ornamental beaches, which, as well as the gutter in front, were dedicated by a certain Antiochus; the orchestra is about 100 ft. in diameter; and in place of the western parados is a closed room called the Scanotheca. The chief peculiarity, however, lies in the great portico already mentioned, which has its base about 4 ft. 6 in. above the level of the orchestra. It was much too lofty to serve as a proscenium; yet, if a proscenium of the ordinary Greek type were erected in front, it would hide the lower part of the columns. Such a proscenium was actually erected in later times; and beneath it were the foundations for an earlier wooden parvis, which was probably erected only when required. In later times steps were added, leading from the base of the portico to the level of the orchestra. The theatre was probably used, like the theatre at Athens, for political assemblies; but the adjoining Thersilion provided covered accommodation for the Arcadian ten thousand in wet weather. It is a building unique in plan, sloping up from the centre towards all sides like a theatre. The roof was supported by columns which were placed in lines radiating from the centre, so as to obscure as little as possible the view of an orator in this position from all parts of the building; there were two entrances in each side.

MEGANUCLEUS (also called Macronucleus), in Infusoria (q.v.), the large nucleus which undergoes direct (amitotic) division in fission, and is lost during conjugation, to be replaced by a nucleus, the result of the karyogamy of the microgametid.

MEGAPODE (Gr. μηγαπός, great and πόδα, foot), the name given generally to a small but remarkable family of birds, characteristic of some parts of the Australian region, to which it is almost peculiar. The Megapodidae, with the Cracidae and Phasianidae, form that division of the sub-order Galli named by Huxley

Peristeropodes (Proc. Zool. Soc., 1868, p. 296). Their most remarkable habit is that of leaving their eggs to hatch without incubation in a nest or in the ground (as many reptiles do), or in a mound of earth, leaves and rotten wood which they scratch up. This habit attracted attention nearly four hundred years ago, but the accounts given of it by various travellers were generally discredited, and as examples of the birds, probably from their unattractive plumage, appear not to have been brought to Europe, no one of them was seen by any ornithologist or scientifically described until near the end of the first quarter of the 19th century. The first member of the family to receive authoritative recognition was one of the brush turkeys of the New Holland vulture. It is the Catheturus lathami of modern ornithologists, and is nearly the size of a hen turkey. This East Australian bird is of a sooty-brown colour, relieved beneath by the lighter edging of some of the feathers, but the head and neck are nearly bare, beset with fine bristles, the skin being of a deep pinkish-red, passing above the breast into a large wattle of bright yellow. The tail is commonly carried upright and partly folded, something like that of a domestic fowl. Allied to it are three or four species of Tuletulus, from New Guinea and adjacent islands.

Another form, an inhabitant of South and West Australia, commonly known in England as the mallee-bird, but to the colonists as the "native pheasant"—the Lipoa ocellata, as described by J. Gould in the Proc. Zool. Soc. (1840), p. 126, has much shorter tarsi and toes, the head entirely clothed, and the tail expanded. Its plumage presents a combination of greys and browns of various tints, interspersed with black, white and buff, the wing-coverts and feathers of the back being dark near the neck, then white. On the left wing is a white patch, beneath which the scientific name of the bird is given, while a stripe of black feathers with a median line of white exceeds down the front of the throat from the chin to the breast. There is but one species of this genus known, as is also the case with the next to be mentioned, a bird long known to inhabit Cebelles, but not fully

1 Antonio Pigafetta, one of the survivors of Magellan's voyage, records in his journal, under date of April 1521, among the peculiarities of the Philippines, that in the first discoveries of the extent of the existence of a bird there, about the size of a fowl, which laid its eggs, as big as a duck's, in the sand, and left them to be hatched by the heat of the sun, was brought by the natives of the islands (described by Valentyn, du Plessis, W. Nieremberg, and published in 1651 in his Historia naturae, published at Antwerp in 1635, described (p. 207) a bird called "Daic," and by the natives named Tapam, "not so large as a dove, and in the crook of its wing there was a white and feet excavated a nest in sandy places and laid therein eggs bigger than those of a goose. The publication at Rome in 1631 of Hernández's Hist. avium novae Hispaniae shows that his papers must have been accessible to Nieremberg, who took from them the passage just mentioned, but, as not used with him, misprinted the names which stand in Hernández's work (p. 56, cap. 220) "Daic" and "Tapam" respectively, and omitted his predecessor's important addition "Vulci in Philippi." Not long after, the Dominican Navarrete, a missionary to China, made a considerable stay in the Philippines, and returning to Europe in 1673 wrote an account of the Chinese egg-laying birds in which Gmelin (Narr. div. ornith. vol. i.) gave an English translation in 1794. It is therein stated (p. 45) that in many of the islands of the Malay Archipelago "there is a very singular bird call'd Tobon," and that "I and many more admire is, that it being no bigger in body than an ordinary chicken, tho' long leg'd, yet it lays an egg larger than a goose, so that the egg is bigger than the bird itself. In order to lay its eggs, it digs in the sand above a yard or in depressions of the ground, holes and middens even with the rest; there the eggs hatch with the heat of the sun and sand." Gemelli Careri, who travelled from 1663 to 1699, and in the latter year published an account of his voyages in the world of science respecting this bird, which he calls "tavon," in the Philippine Islands (Voy. du tour du monde, ed, Paris, 1727, v. 157, 158). The megapode of Luzon is fairly described by Camel or Camelli in the relations of his voyages in the islands, and the Royal Society of London in 1703 (Phil. Trans. xxii. 138). In 1765 Valentyn published his elaborate work on the East Indies, wherein (deel iii. bk. v. p. 320) he correctly describes the megapode under the name of "malleo," and also a larger kind found in Cebelles.
pioneers of Greek commerce. In the Sea of Marmora they had to face the competition of the Samians, with whom they waged a war concerning the town of Perinthus, and of Miletus; but on the Bosphorus they established themselves by means of settlements at Chalcedon and, above all, Byzantium (founded, according to tradition, 675 and 658 respectively). In the Black Sea, they sought to establish colonies in Scythia, whose products they exchanged for textiles spun from the wool of their own country. Their chief colonies in this sea were Astacus and Hercules in Bithynia, and another Hercules in the Crimea. In the later 7th century this current of trade dwindled in face of the great commercial and colonizing activity of Miletus; it probably received further injury through the subsequent interference of Athens on the Hellespont. Simultaneously Megarian commerce in Sicily began to be supplanted by Corinth and Corcyra.

Megara's economic development entailed a change in the distribution of wealth, and consequently of political power, which is commented upon in the elegies of Theognis (g.e.). The original land-holding aristocracy, which had probably initiated and for a time monopolized commerce, was partly supplanted by prosperous columnists, who watched the market, and with the growth of cities retained its hold upon the community of artisans. In the ensuing party struggles the city passed under a tyrant, Theagenes (about 640), who levied duties on the Megaritans and produce great changes. The power of the nobles would seem to have been more effectively broken in a war with Athens, in which Megara ultimately lost the island of Salamis (about 570, see SOLON), for shortly afterwards the commercial supremacy of Athens, and eventually was fixed as an oligarchy of a moderate type.

During the Persian wars the state, which had recently joined the Peloponnesian League, could still muster 3000 hoplites. But the subsequent expansion of Athens ruined the commerce of Megara, and the town itself was threatened with absorption by some powerful neighbour. In 459 an attack by Corinth, which had always coveted Megara's territory, induced the populous Athenians to persuade the Megaritans, who secured Megara in battle and by the construction of long walls between the capital and its port Nisaea. In 445 a revolution of feeling led the Megaritans to massacre their Athenian garrison. The Athenians retaliated by placing an embargo on Megarian trade throughout their empire (432), and in the Peloponnesian War, which the Megaritans had consequently striven to hasten, reduced their neighbours to misery by blockade and devastation. In 424 they nearly captured Megara, in collusion with a democratic party within the town, and succeeded in securing Nisaea, which they held till 410. In the 4th century Megara recovered some of its prosperity, and enjoyed a considerable part in politics, its only notable move being the participation in the final conflict against Philip II. of Macedon (338). During the Macedonian supremacy the town passed in turn from Cassander and Antigonus to the Romans and the Achaemenids. Antius Pollio was incorporated in the Achaean League. Megara suffered severely during the Civil War of 48 b.c., but seems to have lived a considerably new state. It maintained itself as a place of some size in subsequent centuries, and was described by Strabo in a.d. 1500. The inhabitants of the modern village are mostly of Albanian origin.

In literature Megara figures as the reputed home of the comedian Sosion, and in the 4th century gave its name to a school of philosophy founded by Euclid.
northern portion of the western town wall, which in one section served at the same time as an embankment against floods (it was apparently more conspicuous in the time of P. Cluver, Sicilia, p. 133), of an extensive necropolis, about 1000 tombs of which have been explored, and of a deposit of votive objects from a temple. The harbour lay to the north of the town.

See P. Orsi in Monumenti dei Lincei (1891), i. 689–950; and Atti del congresso delle scienze storiche, v. 181 (Rome, 1904). (T. As.)

MEGARIAN SCHOOL OF PHILOSOPHY. This school was founded by Euclides of Megara, one of the pupils of Socrates. Two main elements went to make up the Megarian doctrine. Like the Cynics and the Cyrenaics, Euclides started from the Socratic principle that virtue is knowledge. But into combination with this he brought the Eleatic doctrine of Unity. Perceiving the difficulty of the Socratic dictum he endeavoured to give to the word "knowledge" a definite content by divorcing it absolutely from the sphere of sense and experience, and confining it to a sort of transcendent dialectic or logic. The Eleatic unity is Goodness, and is beyond the sphere of sensible apprehension. This goodness, therefore, alone exists; matter, motion, growth and decay are figments of the senses; they have no existence for Reason.

"Whatever is, is!" Knowledge is of ideas and is in conformity with the necessary laws of thought. Hence Plato in the Sophist describes the Megarians as "the friends of ideas." Yet the Megarians were by no means in agreement with the Platonic idealism. For they held that ideas, though eternal and immovable, have neither life nor action nor movement.

This dialectic, initiated by Euclides, became more and more opposed to the testimony of experience; in the hands of Eubulides and Alexinus it degenerated into hair-splitting, mainly in the form of the reductio ad absurdum. The strength of these men lay in destructive criticism rather than in construction; as dialecticians they were successful, but they contributed little to ethical speculation. They spent their energy in attacking Plato and Aristotle, and hence earned the opprobrious epithet of Eristic. They used their dialectic subtlety to dispove the possibility of motion and decay; unity is the negation of change, increase and decrease, birth and death. None the less, in ancient times they received great respect owing to their intellectual pre-eminence. Cicero (Academica, ii. 42) describes their doctrine as a "nobilis disciplina," and identifies them closely with Parmenides and Zeno. But their most immediate influence was upon the Stoics (p. 2), whose founder, Zeno, studied under Stilpo. This philosopher, a man of striking and attractive personality, succeeded in fusing the Megarian dialectic with Cynic naturalism. The result of the combination was in fact a juxtaposition rather than a compound; it is manifestly impossible to find an organic connexion between a practical code like Cynicism and the transcendental logic of the Megarians. But it served as a powerful stimulus to Zeno, who by descent was imbued with oriental mysticism.

For bibliographical information about the Megarians, see Euclides; Eubulides; Diogenes Laertius; Stilpo. See also Eleatic School; Cynics; Stoics; and, for the connexion between the Megarians and the Eleatics, Menenodemus and Phaedo. Schule; Franz, Geschichte der Logik, i. 52; Henne, L'école de Mégare (Paris, 1842); Gomperz, Greek Thinkers (Eng. trans. 1905), ii. 170 seq.

MEGARON, the principal hall of the ancient Greek palace, situated in the andron or men's quarter. Examples have been found at Tiryns and Mycenae, and references are made to it in the Iliad and the Odyssey.

MEGATHERIUM (properly Megatherium), a huge extinct edentate mammal from the Pleistocene deposits of Buenos Aires, typifying the family Megatheriidae (or Megatheriidae), and by far the largest representative of the Edentata. Except, indeed, for its relatively shorter limbs Megatherium americanum rivalled an elephant in bulk, the total length of the skeleton being 18 feet, five of which are taken up by the tail. The Megatheriidae, which include a number of genera, are collectively known as ground-sloths, and occupy a position intermediate between the sloths and the ant-eater: their skulls being of the type of the former, while their limbs and vertebrae conform in structure to those of the latter. As in the other typical South American edentates, there are no teeth in the front of the jaws, while those of the cheek-sequences usually comprise five pairs in the upper and four in the lower. In nearly all the other Pleistocene forms these teeth were subcylindrical in shape, with the summit of the crown (except sometimes in the first pair) forming a cup-like depression; enamel being in all cases absent. From all these Megatherium differs in the form and structure of the teeth.

In form, as shown in fig. 2, the teeth are quadrangular prisms, each of which is surmounted by a pair of transverse ridges. They grew apparently throughout life, and were implanted to a great depth in the jaws, being 7 or 8 in. in length, with a cross-section of at least an inch and a half. The ridges on the crown are due to the arrangement of the vertical layers of hard dentine (fig. 3 d), softer vaso-dentine (c) and cement (e). The skull is relatively small, with the lower jaw very deep in its central portion, and produced in part into a long snout-like symphysis for the reception, doubtless, of a large and fleshy tongue (fig. 2). Unlike sloths, the megatherium has seven cervical vertebrae; and the spines of all the trunk-vertebrae incline backwards. The pelvis and hind-limbs are much more powerful than the fore-quarters; thereby enabling these animals, in all probability, to rear themselves on their hind-quarters, and thus pull down the branches of trees: if not, indeed, in some cases to bodily uproot the trees themselves. Large chevron-bones are suspended to the vertebrae of the tail, which was massive, and probably afforded a support when the monster was sitting up. The humerus has no foramen, and the

FIG. 1.—Skeleton of the Megatherium, from the specimen in the Museum of the Royal College of Surgeons of England. (X$\frac{1}{2}$.)

FIG. 2.—Lower Jaw and Teeth of Megatherium.
whole fore-limb was very mobile. The first front toe was rudimentary, having no phalanges, but the fifth was rather less aborted, although clawless; the other three carried enormous claws, protected by reflected sheaths. The hind-foot is remarkable for the great backward projection of the calcaneum, and likewise for the peculiar shape of the astragalus; the middle toe alone carries a claw, this being of huge size, and endeared like those of the fore foot. No trace of a bony armour in the skin has been detected; but, from the evidence of other genera, it may be assumed that the body was clothed in a coat of long, coarse hair. Although similar teeth occur in the phosphorite beds of South Carolina, which may have been transported from elsewhere, no undoubted remains of *Megatherium* are known from North America.

The typical species ranged from Argentina and Chili to Brazil. For certain small ground-sloths from Patagonia with *Megatheriun*-like teeth, see *Mylodon* (R. L.*).

MEGHNA, a river of India. It forms, in the lower part of its course, the great estuary of the Bengal delta, which conveys to the sea the main body of the waters of the Ganges and the Brahmaputra, which unite at Goalanda in Faridpur district. The united waters, turbid and of great depth, are sometimes split into half a dozen channels by sand-banks, sometimes spread into a wide sheet of water. The river enters the sea by four principal mouths, enclosing the three large islands of Dakshin Shahbazpur, Hatia and Sandwip. It is navigable by native boats and river steamers all the year; but the navigation is difficult and sometimes dangerous on account of shifting sand-banks and snags, and boisterous weather when the monsoon is blowing. The most favourable season is between November and February. Alluvion and diluvion are constantly taking place, especially along the seaboard, and in Noakhali district the land is said to have made rapid advance on the sea; while the islands fringing the mouth are annually being cut away and redeposited in fresh shapes.

The regular rise of the tide is from 10 to 15 ft., and at springs the sea rushes up in a dangerous bore. It is greatest at the time of the biennial equinoxes, when navigation is sometimes impeded for days together. The tidal wave advances like a wall topped with foam of the height of nearly 20 ft., and at the rate of 15 m. an hour; in a few minutes it is past, and the river has changed from ebb to flood tide. A still greater danger is the "storm wave" which occasionally sweeps up the Meghna under a cyclone.

MEHÁDIA, a market town of Hungary, in the county of Krassó-Szörény, 287 m. S.E. of Budapest by rail. Pop. (1890), 2492. The town is the site of the ancient Roman colony *Ad Mediam*, near which passed the Roman road from the Danube to Dacia. It contains the ruins of a fortress, and other Roman remains. In its neighbourhood are the famous Hercules baths (Hungarian, *Herculesfürdö*). These are situated in a narrow rocky ravine in the valley of the Cserna, where there are 22 hot springs, of which nine are in use, the most powerful being the Hercules spring. The springs are all strongly impregnated with salts of sulphur, iodine, bromine and chlorine, and their average temperature is 70° to 145° F. They were famous in the Roman period under the name of *Thermae Herculis* or *Fontes Herculis*. Their popularity is attested by numerous inscriptions and relics. After the fall of the Roman Empire they fell into disuse until 1735, but the eastern born times they have been much frequented.

MEHEMET ALI (1769-1849), pasha and afterwards viceroy of Egypt, was born at Kavala, a small seaport on the frontier of Thrace and Macedonia. His father, an Albanian, was an agha, a small yeoman farmer, and he himself lived in his native town for many years as a petty official and trader in tobacco. In 1798 he became second in command of a regiment of bashi-bazouks, or volunteers, recruited in his neighbourhood to serve against Napoleon in Egypt. He took part in the battle of Aboukir (July 25, 1799), was driven into the sea with the routed Turks, and was saved from drowning by the gig of the British admiral, Sir Sidney Smith. In 1801 he returned to Egypt, in command of his regiment, and on the 9th of May distinguished himself by heading a bold cavalry charge at the battle of Rahmanieh. In the troubled years that followed, Mehemet Ali, leader of a compact body of Albanian clansmen, was in the best position to draw advantage from the struggle for power between the Mamelukes and the representatives of the Porte. In 1803 he cast in his lot with the former; in 1804 he turned against them and proclaimed his loyalty to the sultan; in 1805 the sheiks of Cairo, in the hope of putting a stop to the intolerable anarchy, elected him pasha, and a year later an imperial firman confirmed their choice.

The disastrous British expedition of 1807 followed; and while at Constantinople the prestige of the sultan was being undermined by the series of revolutions which in 1808 brought Mahmund II. to the throne, that of Mehemet Ali was enhanced by the exhibition at Cairo of British prisoners and an avenue of stakes decorated with the heads of British slain.

The situation revealed to the astute Albanian boundless possibilities; his great ambition, in spite of his chance victories, he was too shrewd an observer not to recognize the superiority of European methods of warfare; and as the first step towards the empire of which he dreamed he determined to create an army and a fleet on the European model. In 1808 the building and organization of the navy was begun with the aid of French officers and engineers. In 1811 the massacre of the Mamelukes left Mehemet Ali without a rival in Egypt, while the foundations of his empire beyond were laid by the war against the Wahhabí and the conquest of the holy cities of Mecca and Medina. The Wahhabí War, indeed, dragged on till 1818, when Ibrahim (q.v.), the pasha's son, who in 1816 had driven the remnant of the Mamelukes into Nubia, brought it to an end. This done, the pasha turned his attention southward to the vast country watered by the Upper Nile. In 1820 the oasis of Siwa was subdued by his arms; in 1823 he laid the foundations of Khartum.

By this time Mehemet Ali was the possessor of a powerful fleet and of an army of veterans disciplined and drilled by European officers. To obtain these money had been necessary; and to raise money the pasha had instituted those internal "reforms"—the bizarre system of state monopolies and the shrewy experiments in new native industries which are described in the article Egypt (q.v.). The inherent viciousness of these expedients had, however, not as yet been revealed by their inevitable results, and Mehemet Ali in the eyes of the world was at once the most enlightened and the most powerful of the sultan's vails. To Mahmund II., whose whole policy was directed to strengthening the authority of the central power, this fact would have sufficed to make him distrust the pasha and desire his overthrow, and it was sorely against his will that, in 1822, the ill-success of his arms against the insurgent Greeks forced him to summon Mehemet Ali to his aid.

The immediate price was the pashalik of Crote; in the event of the victory of the Egyptian arms the pashaliks of Syria and Damascus were to fall to Mehemet Ali, that of the Morea to his son Ibrahim. The part played by Mehemet Ali in the Greek War is described elsewhere (see Turkey: History; Greece: History; Greek Independence, War of
Ibrahim). The intervention of the powers, culminating in the shattering of the Egyptian fleet at Navarino (q.v.), robbed him of his reward so far as Greece was concerned; the failure of his arms in face of this intervention gave Sultan Mahmud the excuse he desired for withholding the rest of the stipulated price of his assistance.

This disappointment of his ambition would not perhaps in itself have sufficed to stir Mehemet Ali to revolt against his master. His desire for prestige was too strong in his nature to allow of this. On the contrary, he now felt that his revolution was justified. But he was now possessed with the idea of shattering the power of the vassals; and, since he was surrounded and counselled by the personal enemies of the pasha of Egypt, it was likely that, so soon as he should feel himself strong enough, he would deal in like manner with Mehemet Ali. It was to anticipate this peril that Mehemet Ali determined himself to open the struggle: on the 1st of November 1832 a force of 9000 Egyptian infantry and cavalry crossed the frontier into Syria and met at Jaffa the fleet which brought Ibrahim as commander-in-chief. The combined forces at once laid siege to St Jean d'Acre.

The stubborn resistance of the garrison delayed Ibrahim's progress; and, meanwhile, wild rumours went abroad as to Mehemet Ali's intentions. He was master of the holy cities, and the official Moniteur Ottoman denounced his supposed plan of aiming at the caliphate in collusion with the sherry of Mecca. As for the pasha himself, he loudly disclaimed any such disloyal pretensions; his aim was to chastise Abdullah, pasha of Acre, who had harboured refugees from his 'reforms' to come, to overthrow the Khurev, who had encouraged him in his refusal to surrender them; to secure the fulfilment of the sultan's promise with regard to Syria and Damascus. Mahmud, on the other hand, was torn between hatred of the pasha and hatred of the Christian powers which had forced him to make concessions to the Greeks. Voices urged him to come to terms with Mehemet Ali, secure peace in Islam, and turn a united face of defiance against Europe; and for a while he harboured the idea. He was conscious of his own intense unpopularity, the outcome of his efforts at reform; he knew that in popular opinion Mehemet Ali was the champion of Islam; the instigations of the infidel caliph, and that the issue of a struggle with him was more than doubtful. He was hampered by the unpaid debt to Russia; by unrest in Bosnia and Albania; above all, by the revolt of the Greek islands, which had left his navy, deprived of its best sailors, in no condition to dispute the Egyptian command of the sea. In the end, however, his pride prevailed; in April 1833 the Turkish commander-in-chief Hussein Pasha left Constantinople for the front; and in the third week in May the ban of outlawry was launched against Mehemet Ali.

Meanwhile, Ibrahim had occupied Gaza and Jerusalem as well as Jaffa; on the 27th of May, a few days after the publication of the ban, Acre was stormed; on the 13th of June the Egyptians occupied Damascus. Ibrahim pressed on with characteristic rapidity, his rapid advance being favoured by the friendly attitude of the various sections of the Syrian population, whom he had been at pains to conciliate. He defeated the Ottoman advance-guard at Homs on the 9th of July and at Hamah on the 11th, entered Aleppo on the 17th, and on the 29th inflicted a crushing defeat on the main Turkish army under Hussein Pasha at the pass of Belban. All Syria was lost to the sultan, and the Egyptian advance-guard passed the mountain defiles into Adana in Asia Minor.

Mahmud, in desperation, now turned for help to the powers. Russian aid, though promptly offered, was too double-edged a weapon to be used save at the last extremity. Austrian diplomacy was, for the moment, that of Russia. France had broken her long tradition of friendship for Turkey by the occupation of Algiers. Great Britain, prodigal of protestations of goodwill, alone remained; and to her Mahmud turned with a definite offer of an offensive and defensive alliance. Stratford Canning, who was at Constantinople for the purpose of superintending the negotiations for the delimitation of the frontiers of Greece, wrote home urging the government to accept, and suggesting a settlement of the Egyptian question which foreshadowed that of 1841. Palmerston, however, did not share Canning's belief in the possible regeneration of Turkey; he held that an isolated intervention of Great Britain would mortally offend not only Russia but France, and that Mehemet Ali, disappointed of his ambitions, would find in France a support that would make him doubly dangerous.

The autumn Sultan Mahmud, as a last independent effort, despatched against Ibrahim the army which, under Rezib Pasha, had been engaged in pacifying Albania. The result was the crowning victory of the Egyptians at Konia (Dec. 21). The news reached Constantinople at the same time as Count Muravyev arrived on a special mission from the tsar. The Russian offers were at once renewed of a squadron of battleships and of a land force for the protection of the capital. Efforts were made to escape the necessity of accepting the perilous aid. Ottoman agents, backed by letters from the French chargé d'affaires, were sent to Mehemet Ali and to Ibrahim, to point out the imminence of Russian intervention by Mehemet Ali of the sultan's terms. Ibrahim himself went to Alexandrie, where, backed by the Austrian agent, Count Prokesch-Osten, he announced to the pasha the tsar's immutable hatred of rebels. Mehemet Ali merely protested the complete loyalty of his intentions; Ibrahim, declaring that as a soldier he had no choice but to obey his father's orders, advanced to Afiun-Karahissar and Kutiah, whence he wrote to the sultan asking his gracious permission to advance to Brusa. He was at the head of 100,000 men, well organized and flushed with victory; the Ottoman army survived only as demoralized rabble. Panic seized the Seraglio; and at the beginning of February the assistance of Russia was formally demanded. The representatives of France and Great Britain made every effort to secure a reversal of this fatal step; but, while they were threatening and promising, Russia was acting, and on the 20th of February a Russian squadron entered the Bosphorus.

In view of this it became necessary for the objecting powers to take a new line. The new French ambassador, Admiral Roussin, had arrived on the 17th; he now, with the full concurrence of Maunder, the British chargé d'affaires, persuaded the Porte to invite the Russians to withdraw, undertaking that France would secure the acceptance by Mehemet Ali of the sultan's terms. A period of suspense followed. The Russian squadron was detained by contrary winds, and before it could sail peremptory orders arrived from the tsar for it to remain until Ibrahim should have repassed the Taurus mountains. Meanwhile, Mehemet Ali had scornfully rejected the offers of the Porte; he would be content with nothing but the concession of his full demands—Syria, Iclleli, Aleppo, Damascus and Adana. The crisis was precipitated by the arrival on the 5th of April of a second division of the Russian fleet in the Bosphorus, and of a Russian force of 6000 men, which landed on the Asiatic shore. The Porte now tried once more to modify its terms; but the Western powers were now intent on getting rid of the Russians at all costs, and as a result of the pressure they brought to bear on both parties the preliminary convention of Koutiaia, conceding all the Egyptian demands, was signed on the 8th of April, and Ibrahim began his withdrawal. The convention stipulated for the bestowal of the pashalik of Adana on Ibrahim; but when on the 16th he received the official list of appointments, he found that the list had been already reserved by the sultan. He at once arrested his march; but the pressure of famine in the capital, caused by the cutting off of supplies from Asia and the presence of the large Russian force, compelled Mahmud to yield, and on the 3rd of May a firman ceded Adana to Ibrahim under the pretext of appointing him muhassil, or collector of the revenue.

When Lord Ponsonby, the new British ambassador, arrived at
Constantinople on the 1st of May he found Russia practically in possession. Sultan Mahmod was to the last degree embittered against the powers which, with lively protestations of friendship, had forced him to humiliate himself before his hated vassal. Russia had given him deeds, not words; and to Russia he committed himself. At the beginning of the summer several Russian frigates and gunboats had arrived on the 22nd of April; Russian engineers were busy with the fortifications along the Straits; Russian agents alone were admitted to the sultan's presence. "It is a manifest," wrote Lord Ponsonby, "that the Porte stands in the relation of vassal to the Russian government." The relation was soon to be yet more manifest. Before, on the 9th of July, the Russian fleet, with the Russian troops on board, weighed anchor for the Black Sea, there was signed at the palace of Unkia Skhessi the famous treaty (July 8, 1833) which, under the guise of an offensive and defensive alliance, practically made Russia the custodian of the gates of the Black Sea. (See Turkey: History.)

Mehemet Ali had triumphed, but he was well aware that he held the fruits of his victory by a precarious tenure. He was still but a vassal among the rest, holding his many pashaliks nominally by the sultan's will and subject to annual reappointment; and he knew that both his power and his life would be forfeit so soon as the sultan should be strong enough to deprive of them. To achieve this one end he had, indeed, become the overmastering passion of Mahmod's life, to defeat it the object of all Mehemet Ali's policy. So early as 1834 it seemed as though the struggle would be renewed; for Mehemet Ali had extended to his new pashalis his system of monopolies and conscription, and the Syrians, finding that they had exchanged Turkish whips for Egyptian scorpions, rose in a passion of revolt. It needed the intervention of Mehemet Ali in person before, in the following year, they were finally subdued. Meanwhile it had need of all the diplomatic armoury of the powers to prevent Mahmod hastening to the assistance of his "oppressed subjects." The threats of Great Britain and France, the failure of Russia to back him up, induced him to refrain; but sooner or later a renewal of the war was inevitable; for the sultan, with but one end in view, was reorganizing his army, and Mehemet Ali, who in the autumn of 1834 had assumed the style of vicecy and sounded the powers as to their attitude in the event of his declaring his complete independence, refused to continue to pay tribute which he knew would be used against himself.

The crisis came in 1838. In March the Egyptians were severely defeated by the revolted Arabs of the Hauran; and the Porte, though diplomatic pressure kept it quiet, hurried on preparations for war. Mehemet Ali, too, had small reason for postponing the conflict. The work of Moltke, who with other German officers who had been engaged in organizing the Turkish army, threatened to destroy his superiority in the field; the commercial treaty signed by the Ottoman government with Great Britain (Aug. 10), which applied equally to all the territories under his rule, threatened to destroy at a blow the lucrative monopolies which supplied him with the sinews of war. Months of suspense followed; for the powers had threatened to cast their weight into the scale against whichever side should prove the aggressor, and Mehemet Ali was too astute to make the first move. In the end Mahmod's passion played into his hands. The old sultan thirsted to crush his rebellious vassal, at any cost; and on the 21st of April 1839 the Ottoman army, stationed at Bir on the Ephrates, crossed the stream and invaded Syria. On the 23d of June it was attacked and utterly routed by the Egyptians. On the 28th the old sultan died, unconscious of the fatal news, leaving his throne to Abd-ul-Mejid, a lad of sixteen. To complete the desperateness of the situation the news reached the capital that Ahmed Pasha, the Ottoman admiral-in-chief, had sailed to Alexandria and surrendered his fleet to Mehemet Ali, on the pretext that the sultan's advisers were sold to the Russians.

So far as the forces of the Ottoman Empire were concerned, Mehemet Ali was now absolute master of the situation. The grand vizier, in the sultan's name, wrote beseeching him to avoid the further shedding of Musulman blood, offering him a free pardon, the highest honours of the state, the hereditary pashalik of Egypt for himself, and Syria for Ibrahim until he should succeed his father in Egypt. Mehemet Ali replied diplomatically; for, though these offers fell far short of his ambitions, a studious moderation was essential in view of the doubtful attitude of the European powers.

On the 27th of July the ambassadors of the five powers presented to the Porte a joint note, in which they declared that an agreement on the Eastern Question had been reached by the five Great Powers, and urged it "to suspend all definite decision made without their concurrence, pending the effect of their interest in its welfare." The necessity for showing a united front justified the diplomatic inexactitude; but the powers were agreed on little except the need for agreement. Especially was this need realized by the British government, which feared that Russia, would seize the occasion for an isolated intervention under the treaty of Unkia Skhesi. On the 1st of August Palmerston wrote to Ponsonby impressing upon him that the representatives of the powers, in their communications with the Porte, "should act not only simultaneously in point of time, but identically in point of manner"—a principle important in view of later developments. It was, however, impossible to preserve the appearance of unanimity in view of the divergent views within the concert. France and Great Britain had hitherto acted together through common opposition to the supposed designs of Russia. Austria, too, now that the revolutionary spectres of 1848 had been laid, was reverting to her traditional opposition to Russia in the affairs of the Near East, and Metternich supported Palmerston's proposal of an international conference at Vienna. Everything depended on the attitude of the emperor Nicholas. This was ultimately determined by his growing disaffection towards France and his personal hatred of the democratic regime of France. The first caused him to reject the idea of a conference of which the activities would have been primarily directed against Russia; the second led him to drive a wedge into the Anglo-French entendre by making direct overtures to Great Britain. Palmerston listened to the tsar's proposals, conveyed through Baron Brunnow, with "surprise and admiration." The emperor Nicholas was prepared to accept the views of Great Britain on the Turco-Egyptian question; to allow the Treaty of Unkia Skhesi to lapse; to act henceforth in the Ottoman Empire only in concert with the other powers; to resist the pashalik of Egypt for himself; and, lastly, to pluck the benefit of the Dardanelles to the war-ships of all nations and to extend the same principle to the Bosporus. Finally, Brunnow was empowered to arrange a coalition of the great powers with a view to the settlement of the Egyptian question; and in this coalition the tsar was willing, for political reasons, that France should be included, though he stated his personal preference for her exclusion.

To these views Austria and, as a natural consequence, Prussia acceded without difficulty. The attitude of France was a more doubtful quantity. In France Mehemet Ali had become a popular hero; under him French civilization had gained a foothold in Egypt; he was regarded as invincible; and it was hoped that in alliance with him French influence in the Mediterranean would be supreme. Palmerston, on the other hand, believed that the Ottoman empire would never become sure until "the desert had been placed between the pasha of Egypt and the sultan; and the view that the coalition should be directed against Mehemet Ali was shared by the other powers. In the circumstances France should either have loyally accepted the decision of the majority of the conference, or return for an agreement closing the Dardanelles to the war-ships of all nations and to extend the same principle to the Bosporus. Finally, Brunnow was empowered to arrange a coalition of the great powers with a view to the settlement of the Egyptian question; and in this coalition the tsar was willing, for political reasons, that France should be included, though he stated his personal preference for her exclusion.

To these views Austria and, as a natural consequence, Prussia acceded without difficulty. The attitude of France was a more doubtful quantity. In France Mehemet Ali had become a popular hero; under him French civilization had gained a foothold in Egypt; he was regarded as invincible; and it was hoped that in alliance with him French influence in the Mediterranean would be supreme. Palmerston, on the other hand, believed that the Ottoman empire would never become sure until "the desert had been placed between the pasha of Egypt and the sultan; and the view that the coalition should be directed against Mehemet Ali was shared by the other powers. Finally, Brunnow was empowered to arrange a coalition of the great powers with a view to the settlement of the Egyptian question; and in this coalition the tsar was willing, for political reasons, that France should be included, though he stated his personal preference for her exclusion.

So far as the forces of the Ottoman Empire were concerned,
Egypt, a proposition to which Palmerston, though sincerely anxious to preserve the Anglo-French entente, refused to agree. The tension of the situation was increased when, on the 20th of February 1840, Thiers came into power. The diplomacy of Guizot, backed now by Austria and Prussia, had succeeded in persuading Palmerston to concede the principle of allowing Mehemet Ali to receive, besides Egypt, the pashalik of Acre as far as the frontiers of Tripoli and Damascus (May 7). Thiers, however, refused to listen to any suggestions for depriving him of any part of Syria; but, instead, breaking off the correspondence and leaving the concert, he continued the negotiations, and before long circumstances came to the knowledge of the British government which seemed to prove that he was only doing so with a view to gaining time in order to secure a separate settlement in accordance with French views.

The opportunity for this arose from a change in the situation at Constantinople, where the dismissal of Khusrv Pasha had, in Mehemet Ali's view, removed the main obstacle to his reconciliation with the sultan. He proposed to the French consul-general at Alexandria to make advances to the Porte, and suggested sending back the Ottoman fleet as an earnest of his good intentions, a course which, it was hoped, "would lead to a direct and amicable arrangement of the Turco-Egyptian question." On the 21st of June his envoy, Sami Bey, actually arrived at Constantinople, ostensibly to congratulate the sultan on the birth of a daughter, really to make use of the French influence now supreme at the Porte in order to effect a settlement. In the circumstances the proper course for Thiers to have pursued would have been to have communicated to the powers, to whom he was bound by the moral engagement of the 27th of July 1839, the new conditions arising out of Mehemet Ali's offer. Instead he wrote to Guizot, on the 30th of June, saying that the situation argued strongly in favour of postponing any decision in London, adding: "I have written to Alexandria and Constantinople to counsel moderation on both sides; but I have been careful to forbid the agents to enter on their own account, and as a French undertaking, on a negotiation of which the avowed aim is a direct arrangement. If such an enterprise is imputed to us, you will be in a position to deny it."

The discovery of what seemed an underhand intrigue on the part of France produced upon the powers exactly the effect that Thiers had desired. The result of it was an attempt to ruin the work of the concert and to secure for France a "complete individual triumph" at Alexandria and Constantinople; and their countermove was to sign at London on the 15th of July, without the concurrence of France, a convention with the Porte for the settlement of the affairs of the Levant. By this instrument it was agreed that the terms to be offered to Mehemet Ali having been concerted with the Porte, the signatory powers would unite their forces in order to compel the pasha to accept the settlement. As to the terms to be offered, it was arranged that, in the event of Mehemet Ali yielding within ten days, he should receive the hereditary pashalik of Egypt and the administration for life of southern Syria, with the title of Pasha of Acre and the possession of the fortress of St Jean d'Acre. At the end of ten days, should he remain obdurate, the offer of Syria and Acre would be withdrawn; and if at the end of another ten days he was still defiant, the sultan would hold himself at liberty to withdraw the whole offer and to take such measures as his own interests and the counsels of his allies might suggest to him.

The news of this "mortal affront" to the honour of France caused immense excitement in Paris. The whole press was clamorous for war. Thiers declared that the alliance with Great Britain was shattered, and pressed on warlike preparations; even Louis Philippe was carried away by the fever. The immediate effect was that Mehemet Ali, confident of French assistance, maintained a defiant attitude. The situation, however, was rapidly changed by the unexpected results of the armed intervention of the Allies. The appearance of the combined British, Austrian and Russian fleets, under Sir Charles Napier, off Beirut (Aug. 11) was the signal for a general rising of the Syrians against Ibrahim's tyranny. On the 11th of September, Suleiman Pasha not having obeyed the summons to evacuate the town, the bombardment was begun, and Ottoman troops were landed to co-operate with the rebels. On the 3rd of October Beirut fell; and Ibrahim, cut off from his communications by sea, and surrounded by a hostile population, began a hurried retreat southward. On the 3rd of November Acre surrendered to the allied fleet. Mehemet Ali's power in Syria had collapsed like a pricked bubble; and with it had gone for ever the myth of his humane and enlightened rule. The sole question now was whether he should be allowed to retain Egypt itself.

On the 15th of September the sultan, who had broken off all negotiations with Mehemet Ali on receipt of the news of the Syrian revolt, acting on the advice of Lord Ponsonby, declared the pasha deposed, on the ground that the term allowed by the Convention of London had expired, and nominated his successor. Mehemet Ali received the news with his accustomed sang-froid, observing to the consuls of the four powers, who had come to notify their own removal, that "such denunciations were nothing new to him, and that he hoped to get over it as well as he had done the other three with the help of God and the Prophet." In the end his confidence proved to be justified. The news of the events in Syria and especially of the deprivation of Mehemet Ali had produced in France what appeared to be an exceedingly dangerous temer; the French government declared that it regarded the maintenance of Mehemet Ali in Egypt as essential to the European balance of power; and Louis Philippe sought to make it clear to the British government, through the king of the Belgians, that, whatever might be his own desire to maintain peace, in certain events to do so would be to risk his throne. Palmerston, indeed, who did not believe that under the Bourgeois Monarchy France would translate her brave words into action, was in favour of settling the Turco-Egyptian question once for all by depriving Mehemet Ali of Egypt as well. The influences against him, however, were too powerful. Metternich protested against a course which would result, in his opinion, either in a war or a revolution in France; King Leopold enlarged on the wickedness and absurdity of risking a European war for the sake of putting an end to the power of an old man who could have but few years to live; Queen Victoria urged that this was the fourth time to come to terms with France; and relieve the embarrassment of the "dear King"; and Lord Melbourne, with the majority of the cabinet, was in favour of compromise. When therefore, on the 5th of October, Guizot, in an interview with Palmerston, presented what was practically an ultimatum on the part of France, "it was determined that this intimation should be met in a friendly spirit, and that Lord Palmerston should see the Ministers of the other powers and agree with them to acquaint the French that they with England would use their good offices to induce the Porte not to insist on the deprivation of Mehemet Ali so far as Egypt is concerned." In accordance with this Palmerston instructed Ponsonby to cease not only to withdraw the sentence of deprivation but to confer upon him the hereditary pashalik of Egypt.

For a while it seemed that even this would not avert a European war. Thiers still maintained his warlike tone, and the king's speech prepared by him for the opening of the Chambers on the 28th of October was in effect a declaration of defiance to Europe. Louis Philippe himself, however, was not prepared to use this language; whereupon Thiers resigned, and a new cabinet was formed under General Soult, with Guizot as foreign secretary. The equivocal tone of the new speech from the Throne raised a storm of protest in the Chambers and the country. It was, however, soon clear that Palmerston's diagnosis of the temper of the French bourgeoís was correct; the clamour for war subsided; on the 4th of December the address on the Egyptian Question proposed by the government was carried, and peace was assured. Nine days earlier Sir Charles Napier had appeared with a British squadron off Alexandria and, partly by persuasion, partly by threats, had induced Mehemet Ali to submit to the sultan and to send back the Ottoman fleet, in return for a guarantee
of the hereditary pashalik of Egypt. This arrangement was ratified by Palmerston; and all four powers now combined to press it on the reluctant Porte, pointing out, in a joint note of the 30th of January 1841, that "they were not conscious of advising a course out of harmony with the sovereignty and legitimate rights of the sultan, or contrary to the duties imposed on the Pasha of Egypt as a subject appointed by His Highness to govern a province of the Ottoman Empire." This principle was elaborated in the firman, issued on the 13th of February, by which the sultan conferred on Mehemet Ali and his heirs by direct descent the pashalik of Egypt, the greatest care being taken not to bestow any rank and authority greater than that enjoyed by other viziers of the empire. By a second firman of the same date Mehemet Ali was invested with the government of Nubia, Dafur, Khordofan and Sennar, with their dependencies. On the 10th of June the firman was solemnly promulgated at Alexandria.

Thus ended the phase of the Egyptian Question with which the name of Mehemet Ali is specially bound up. The threatened European conflict had been averted, and presently the wounded susceptibilities of France were healed by the invitation extended to her to take part in the Straits Convention. As for Mehemet Ali himself, he now passes off the stage of history. He was an old man; his mind was soon to give way; and for some time before his death on the 2nd of August 1849 the reins of power were held by his son and successor Ibrahim.

Probably no Oriental ruler, not even excepting Ali of Jannina, has ever stirred up so much interest among his contemporaries as Mehemet Ali. The spectacle of an Eastern despot apparently advancing on the lines of European progress was in itself as astonishing as new. Men thought they were witnessing the dawn of a new era in the East; Mehemet Ali was hailed as the most beneficent and enlightened of princes; and political philosophers like Jeremy Bentham, who sent him elaborate letters of good advice, thought to find in him the means for developing their theories in virgin soil. In fact the pasha was an illiterate barbarian, of the same type as his countryman Ali of Jannina, courageous, cruel, astute, full of wiles, avaricious and boundlessly ambitious. He never learned to read or write, though late in life he mastered colloquial Arabic; yet those Europeans who were brought into contact with him praised alike the dignity and charm of his address, his ready wit, and the astonishing perspicacity which enabled him to read the motives of men and of governments and to deal effectively with each situation as it arose.

The latest account of Mehemet Ali and the European crisis arising out of his revolt is that by W. Allison Phillips in vol. x. ch. xvii. of the Cambridge Modern History (1907). The bibliography attached to this chapter (p. 852) gives a list of all the principal publications in English and French; with a list of four of the unpublished Foreign Office records bearing on the subject.

Of the works mentioned C. de Freycinet's La Question d'Egypte (Paris, 1863) gives the most authoritative account of the diplomatic developments.

(W. A. P.)

MEHIDPUR, or MAHIDPUR, a town of India, in Indore state of Central India, on the right bank of the Soom, 1543 ft. above the sea, and 24 m. N. of Ujjain. Pop. (1901), 69,851.

Though of some antiquity and frequented by Hindu pilgrims, it is best known for the battle fought in the neighbourhood on the 20th of December 1817, in which Sir John Malcolm defeated the army of Holkar. The result was the Treaty of Mandasor and the pacification of Malwa. Mehidpur was again the scene of some sharp fighting during the Mutiny. The British cantonment, placed here in 1817, was removed in 1884.

MÉHUL, ÉTIENNE HENRI (of ÉTITENE NICOLAS) (1763–1817), French composer, was born at Givet in Ardennes, on the 24th of June 1763. His father being too poor to give him a regular musical education, his first ideas of art were derived from a poor blind organist of Givet; yet such was his aptitude that, when ten years old, he was appointed organist of the convent of the Récollets. In 1775 an able German musician and organist, Wilhelm Hauser, was engaged for the monastery of Lavaldieu, a few miles from Givet, and Méhul became his occasional pupil. In 1778 he was taken to Paris by a military officer, and placed himself under Edelmann, a good musician and harpsichord player. His first attempts at instrumental composition in 1781 did not succeed, and he therefore turned his attention to sacred and dramatic music. Gluck gave him advice in his studies. After various disappointments during his efforts for six years to obtain, at the Grand Opéra, a representation of his Cora et Alonso, he offered to the Opéra Comique his Euphrosine et Coradin, which, being accepted and performed in 1790, at once fixed his reputation. His opera of Strattonie was also received with enthusiasm in 1792. After several unsuccessful operas, his Adrien appeared, and added much to his fame, which was further increased by his three best works, Le Jeune Henri, Uthal and Joseph, the finest of the series. Uthal was written for an orchestra without violins. Méhul held a post as one of the four inspectors of the Paris Conservatoire, but this office made him feel continually the insufficiency of his early studies, a want which he endeavoured to remedy by incessant application. Timoleon, Aridant and Bien followed. Épicure was composed by Méhul and Cherubini jointly; but the superiority of the latter was evident. Méhul's next opera, L'Erato, failed. After writing forty-two operas, besides a number of songs for the festivals of the republic, cantatas, and oratorio, and pieces of various kinds, his health gave way, from an affection of the chest, and he died on the 18th of October 1817 in Paris.

See Lives by Pougin (1889), Viellard (1899), and Quatremère de Quincy (1818).

MEIBOM, HEINRICH (1555–1625), German historian and poet, was born at Lengmo on the 4th of December 1555, and died on the 20th of September 1625, at Helmstedt, where he had held the chair of history and poetry since 1583. He was a writer of Latin verses (Parodiares horatianarum libri III. et syulborum libri II.), and his talents in this direction were recognized by his contemporary Rudolph II., who ennobled him; but his claim to be remembered rests on his services in elucidating the medieval history of Germany.

His Opuscula historica ad res germanicas spectantia was edited and published in 1660 by his grandson, Heinrich Meibom (1638–

1700), who was professor of medicine and then of history and poetry at Helmstedt, and incorporated his grandfather's work with his own Rerum germaniarum scriptores (1688).

MEIDERICH, a town of Germany, in the Prussian Rhine province, 23 m. by rail N.E. of Ruhrort, whose river harbour is in great part within its confines. Pop. (1905), 40,822. Iron and steel works, coal-mines, saw-mills, brickworks, and machine-shops furnish the principal occupations of the inhabitants. Meiderich, which is first mentioned in 874, was united with Duisburg in 1905.

See Graeber, Tausendjährige Geschichte von Meiderich (1893).

MEIKTILA, a district and division in Upper Burma. The district is the most easterly of the districts in the dry zone, and has an area of 2185 sq. m. It lies between Kayuksé, Mulingyan, Yamethin, and on the east touches the Shan States. It is a slightly undulating plain, the gentle slopes of which are composed of black "cotton" soil and are somewhat arid. The only hills above 300 ft. are on the slopes of the Shan hills. The lake is the chief feature of the district. It is artificial, and according to Burmese legend was begun 2400 years ago by the grandfather of Gautama Buddha. It is 7 m. long, averages half a mile broad, and covers an area of 32 sq. m. With the Mhinla and other connected lakes it irrigates a large extent of country.

There are small forest reserves, chiefly of cutch. Large numbers of cattle are bred. The chief agricultural products are rice, sesameum, cotton, peas, maize, millet and gram. Pop. (1901), 252,935. Famines in 1891, 1895 and 1896 led to considerable emigration. The climate is healthy except in the submontane乡镇ships. The temperature rises to 100° F. and over between the months of March and June, and the mean minimum in January is about 61°. The rainfall is uncertain (36-79 in. in 1893, 23-59 in 1891). The vast majority
of the population are Buddhists. The headquarters town, Meiktila, stands on the banks of the lake, which supplies good drinking water. Pop. (1901), 7203. A wing of a British regiment is stationed here. A branch railway connects it at Thazi station with the Rangoon-Mandalay line, and continues westward to its terminus on the Irrawaddy at Myingyan.

The division includes the districts of Meiktila, Kyaukse, Yamethin and Myingyan, with a total area of 10,852 sq. m., and a population (1901) of 92,807, showing an increase of 10-2% in the preceding decade, and giving a density of 91 inhabitants to the square mile. All but a small portion of the division lies in the dry zone, and cultivation is mainly dependent on irrigation.

MEILHAC, HENRI (1831-1897), French dramatist, was born in Paris on the 21st of February 1831, and while a young man began writing fanciful articles for the newspapers and vaudevilles for the theatres, in a vivacious boulevardier spirit which brought him to the front. About 1860 he met Ludovic Halévy, and the two began a collaboration in writing for the stage which lasted for twenty years. An account of their work is given under Halévy. Meilhac wrote a few pieces with lesser collaborators. In 1888 he was elected to the Academy. He died at Paris in 1897.

MEINBERG, a village and watering-place of Germany, in the principality of Lippe Detmold, situated in a pleasant valley under the Teutoburger Wald, 12 m. S.E. from Detmold by the railway to Altenbeken. Pop. (1905), 1300. The waters of Meinberg, which attracts annually about 1200 visitors, are sulphur springs, and are used for drinking, bathing and inhalation. They became known in the 18th century.

See Gilbert and Meisner, Bad Meinberg und seine Kurmittel (Berlin, 1902).

MEIKE, JOHANN ALBRECHT FRIEDRICH AUGUST (1790-1870), German classical scholar, was born at Soest in Westphalia on the 8th of December 1790. After holding educational posts at Jenkau and Danzig, he was director of the Joachimsthal gymnasia in Berlin from 1826 to 1836. He died at Berlin on the 12th of December 1870.

He was distinguished in conjectural criticism, the comic writers and Alexandrine poets being his favourite authors.

His most important works are: Gracorum comicorum fragmenta (1830-1837), the first volume of which contains an essay on the development of Greek comedy and an account of its chief representatives; Aristophanes (1860); Alaeuta alexandrina (1843, containing the fragments of Rhianus, Euphorion, Alexander of Aetolia, and Parthenius); Callimachus (1861); Theocritus, Bion, Moschus (3rd ed., 1856); Alciphron (1853); Strabo (2nd ed., 1866), and Vendicatae strabianae (1852); Stobaeus (1855-1863); Athenaeus (1856-1865). See monographs by F. Ranke (1871), H. Sauppe (1872), and E. Forster in Allgemaine deutsche Biographie. XXI. (1885); also Sandys, Hist. Class. Schol. (1908), iii. 117.

MEININGEN, a town of Germany, capital of the duchy of Saxe-Meiningen, romantically situated in forests on the right bank of the Werra, 40 m. S. of Eisenach by rail. Pop. (1905), 15,089. It consists of an old town and several handsome suburbs, but much of the former has been rebuilt since a fire in 1874. The chief building is the Elisabethenburg, or the old ducal palace, containing several collections; it was built mainly about 1850, though part of it is much older. Other buildings are the Henneberger Haus with a collection of antiquities, and the town church, with twin towers, built by the emperor Henry II. in the 11th century. The theatre enjoyed for many years (1875-1890) a European reputation for its actors and scenic effects. The English garden, a beautiful public park, contains the ducal mortuary chapel and several monuments, including busts of Brahms and Jean Paul Richter.

Meiningen, which was subject to the bishops of Würzburg (1000-1542), came into the possession of the dukes of Saxony in 1515, having in the meantime belonged to the counts of Henneberg. At the partition of 1660 it fell to the share of Saxe-Altenburg, and in 1680 became the capital of Saxe-Meiningen.

See E. Döbner, Bausteine zu einer Geschichte der Stadt Meiningen (Meiningen, 1902).

MEIR, Jewish rabbi of the 2nd century, was born in Asia Minor and according to legend was a descendant of the family of Nero. He was the most notable of the disciples of Aquila (g.v.), and after the Hadrianic represses of A.D. 135 was instrumental in refounding the Palestinian schools at Usha. Among his teachers was also Elisha ben Abuya (g.v.), and Meir continued his devotion to Elisha after the latter's apostasy. He is said to have visited Rome to rescue his wife's sister. His wife, Beruriah, is often cited in the Talmud as an exemplar of generosity and faith. She was a daughter of the martyr Hanania ben Tadion. On one occasion Meir, who had been frequently troubled by his ungodly neighbours, uttered the words, "I wish I was dead". "Why wish to die," said his wife, "when you have a wife who prays from morning to night?" Meir’s writing (Ps. civ. 35) let sins be blotted out, not sinners; whereupon Meir prayed for the evildoers' conversion. But she is best known for her conduct at the sudden death of her two sons. It was the Sabbath, and Meir returned home towards sunset. He repeatedly asked for the children, and Beruriah, after parrying his question, said: "Some time ago a precious thing was left with me on trust, and now the owner demands its return. Must I give it back?" "How can you question it?" rejoined her husband. Beruriah then led him to the bed where the children were stretched, and he had to take them into tears. But the wife explained that this was the treasure of which she had spoken, adding the text from Job: "The Lord gave and the Lord hath taken away; blessed be the name of the Lord." Meir himself was the author of many famous sayings: "Look not to the flesh, but to its contents. Many a new vessel contains old wine, but there are old casks which do not contain even new wine." "Condole not with a mourner while his dead is laid out before him." "Man cometh into the world with closed hands as though claiming the ownership of all things; but he departeth hence with hands and a limb, as if to show that he taketh naught with him." "What God does is well done." "The tree itself supplies the handle of the axe which cuts it down." His wisdom was proverbial, and to him was in particular assigned an intimate acquaintance with fables, and he is reported to have known 300 Fox-Fables.

"With the death of Rabbi Meir," says the Mishnah (Sota ix. 13), "Fabulists ceased to be."

Meir's wide sympathies were shown in his inclusion of all mankind in the hopes of salvation (Sifra to Leviticus xviii. 5). He was certainly on friendly terms with the heathen scholars. Meir contributed largely to the body of the material from which finally emerged the Mishnah. His dialectic skill was excessive, and it was said jestingly of him that he could give 150 reasons to prove a thing clean, and as many more to prove it unclean. His balanced judgment fitted him to carry on Aggir's work, sitting and arranging the oral traditions, and thus preparing the ground for the Mishnian Code.

Meir left Palestine some time before his death, owing to disagreements between him and the Patriarch. He died in Asia Minor, but his love for the Holy Land remained dominant to the last; "Bury me," he said, "by the shore, so that the sea, which washes the land of my fathers may touch also my bones." The tomb shown as that of Meir at Tiberias is inauthentic.

See Bacher, Agada der Tannaiten, vol. xi. ch. i.; Graetz, History of the Jews (Eng. trans.), vol. xi. ch. xvi.; Jewish Encyclopedia (whence some of the above cited sayings are quoted), viii. 432-435. On Meir's place in the history of the fable see J. Jacobs, The Fables of Apocryph. l. i. 111, &c. (see Index ix.)

MEIR OF ROTHENBURG (c. 1215-1293), German rabbi and poet, was born in Worms c. 1215. He played a great part in organizing the Jewish communal life of the middle ages. In 1260 for some unknown reason he was thrown into prison in Alsace, where he remained until his death in 1293. His friends offered to find a ransom, but he declined the suggestion, fearing that the precedent would lead to extortions in other cases. He wrote glosses to the Talmud (Toseph) and many Responsa of the utmost value for historical research. Through his disciples Asher ben Yehiel and Mordecai ben Hillel, Meir exercised much
influence on subsequent developments of Judaism. He was also a liturgical poet of considerable merit. One of his finest elegies is translated into English in Nina Davis's *Songs of Exile.*

**MEIRINGEN,** the principal village on the Hasle (or the upper Aar) valley in the Swiss canton of Bern. It is built at a height of 1069 ft. on the right bank of the Aar and on the level floor of the valley, but is much exposed to the south wind (or Pühn), and has several times been in great part destroyed by fire (1654, 1879 and 1891). It has 977 inhabitants, all German-speaking and Protestants. The parish church is ancient, and above it are the ruins of the medieval castle of Resti. Meiringen is frequented by travellers in summer, as it is the meeting-point of many routes: from Interlaken by the lake of Brienz and Brienz, from Lucerne by the Brünig railway (28 m.), from Engelberg by the Joch Pass (767 ft.), from the upper Valais by the Grimsel Pass (7100 ft.), and from Grindelwald by the Great Scheidegg Pass (6434 ft.). Many waterfalls descend the hill-sides, the best known being the Reichenbach and the Alpach, while the great gorge pierced by the Aar through the limestone barrier of the Kirchet is remarkable. The village and valley belonged of old to the emperor, who in 1234 gave the advowson to the Knights of St Lazarus, by whom it was sold in 1272 to the Austin Canons of Interlaken, on the suppression of whom in 1258 it passed to the state. In 1310 the emperor mortgaged the valley to the lords of Weissenburg, who sold it in 1334 to the town of Bern. (W. A. B. C.)

**MEISSEN,** a town of Germany, in the kingdom of Saxony, on both banks of the Elbe, 15 m. N.W. from Dresden, on railway to Leipzig via Döbeln. Pop. (1905), 37,336. The old town lies on the left bank of the river, between the streams Meisse and Triebisch, and its irregular hilly site and numerous fine old buildings make it picturesque. Most of its streets are narrow and uneven. The cathedral, one of the finest early Gothic buildings in Germany, stands on the Schlossberg, 160 ft. above the town. It is said to have been founded by the emperor Otto the Great, but the present building was begun in the 13th century and was completed about 1450. Here are tombs of several rulers and princes of Saxony, including those of Albert and Ernest, the founders of the two existing branches of the Saxon house. The cathedral also contains works by Peter Vischer and Lucas Cranach and several other interesting monuments. A restoration, including the rebuilding of the two towers, was carried out in 1903–1908. Adjoining the cathedral is the castle, dating from 1477–1483, but restored and named the Albrechtsburg about 1576. Another restoration was undertaken after 1862, when a series of historical frescoes was painted upon its walls. A stone building of the 13th century connects the Schlossberg with the Ärftberg, which owes its name to the old convent of St Afra. The convent was suppressed by Duke Maurice in 1543, and was by him converted into a school (the Fürsten Schule), one of the most renowned classical schools in Germany, which counts Lessing and Gellert among its former pupils. Other public buildings of interest are the town-hall, built in 1470 and restored in 1873; the fine town church, called the Frauenkirche or Marienkirche; the Nikolaitkirche and the Afrakirche. The Franciscan church is now used as a museum of objects connected with the history of Meissen. Since 1750 Meissen has been the seat of the manufacture of Dresden china. Till 1869 the royal porcelain factory was in the Albrechtsburg, but in that year it was transferred to a large new building in the Triebischtal, near the town. Meissen also contains iron foundries, factories for making earthenware stoves and pottery, sugar refineries, breweries and tanneries. A considerable trade is carried on in the wine produced in the surrounding vineyards, and other industries are spinning and weaving.

Meissen was founded about 920 by Henry the Fowler (see Meissen, Henry the Fowler). From a charta of 951 Meissen was the seat of a line of bishops, who ranked as princes of the empire. During the 10th century the town suffered greatly from the Hussites, and it was captured by the imperial troops during the war of the league of Schmalkalden, and again in the Thirty Years' War. In 1637 it suffered much from the Swedes, and in 1745 it fell into the hands of the Prussians. The bridge over the Elbe was destroyed by the French in 1813, and again by the Saxons in June 1866 in order to impede the march of the Prussians on Dresden. Colln on the right bank of the Elbe was incorporated with Meissen in 1901.

**MEISSEN,** a German margraviate now merged in the kingdom of Saxony. The mark of Meissen was originally a district centring round the castle of Meissen or Misnia on the Middle Elbe, which was built about 920 by the German king Henry I., the Fowler, as a defence against the Slavs. After the death of Gero, margrave of the Saxon east mark, in 995, his territory was divided into five marks, one of which was called Meissen. In 995 the emperor Otto III. bestowed the office of margrave upon Eckard I., margrave of Merseburg, and the district comprising the marks of Meissen, Merseburg and Zeitz was generally known as the mark of Meissen. In 1002 Eckard was succeeded by his brother Gunzelin, and then by his sons Hermann I. and Eckard II. Under these margraves the area of the mark was further increased, but when Eckard II. died in 1046 it was divided, and Meissen proper was given successively to William and Otto, counts of Weimar, and Egbert II., count of Brunswick. Egbert was a rival of the emperor Henry IV. and died under the imperial ban in 1050. Meissen was restored to the margraves and turned over to Wettin, whose mother was a sister of the margrave Eckard II. Henry, who already ruled in Saxony and the new smaller Saxon east mark, was succeeded in 1103 by his cousin Thimo, and in 1104 by his son Henry II., whose claim on the mark was contested by Thimo's son Conrad. When Henry died without issue in 1123 Meissen was given by the emperor Henry V. to Hermann II., count of Wintzenburg; but, renewing his claim, Conrad won the support of Lothair, duke of Saxony, afterwards the emperor Lothair II., and obtained possession in 1130. Conrad, called the Great, extended the boundaries of Meissen before margraving in 1156 in favour of his son Otto, known as the Rich. Otto appointed his younger son Dietrich as his successor and was attacked and taken prisoner by his elder son Albert; but, after obtaining his release by order of the emperor Frederick I., he had only just renewed the war when he died in 1190. During his reign silver mines were opened in the Harz Mountains, towns were founded, roads were made, and the general condition of the country was improved. Otto was succeeded by his son Albert, called the Proud, who was engaged in warfare with his brother Dietrich until his death in 1215. As Albert left no children, Meissen was seized by the emperor Henry VI. as a vacant fief of the empire; but Dietrich, called the Oppressed, secured the mark after Henry's death in 1197. Dietrich married Jutta, daughter of Hermann I., landgrave of Thuringia, and was succeeded in 1227 by his infant son Henry, surnamed the Illustrious; who on arriving at maturity obtained as reward for supporting the emperor Frederick II. against the pope a promise to succeed his uncle, Henry Raspe IV., as landgrave of Thuringia. In 1243 Henry's son Albert was betrothed to Margaret, daughter of Frederick II.; and Pleißenberg, a district west of Meissen, was added to his possessions. Having gained Thuringia and the Saxony palatinate on his uncle's death in 1247, he granted sections of his lands to his three sons in 1265, but retained Meissen. A series of family feuds followed. His second son Dietrich died in 1285, and on Henry's own death in 1288 Meissen was divided between his two remaining sons, Albert (called the Degenerate) and Frederick, and his grandfather Frederick Tutta, the son of Dietrich. Albert was engaged in struggles with his three sons, who took him prisoner in 1289. He was restored to his freedom by order of the German king Rudolph I. About this time he sold his portion of Meissen to his nephew Frederick Tutta, who held the title
MEISSONIER, J. L. E.

of margrave and ruled the greater part of the mark until his death in 1291. Albert's two remaining sons, Frederick and Dietrich or Diezmann, then claimed Meissen; but it was seized by King Adolph of Nassau as a vacant fief of the empire, and was for some time retained by him and his successor King Albert I. In the course of constant efforts to secure the mark the brothers Frederick and Dietrich defeated the troops of King Albert at Lucka in May 1307 and secured partial possession of their lands. In this year Dietrich died and Frederick became reconciled with his father, who, after renouncing his claim on Meissen for a yearly payment, died in 1319 after inheriting the possession of the greater part of the mark. Frederick was invested with it by the German king Henry VII. in 1310. During these years the part of Meissen around Dresden had been in the possession of Frederick, youngest son of the margrave Henry the Illustrious, and when he died in 1316 it came to his nephew Frederick. About 1332 Frederick, who had become involved in a dispute with Waldemar, margrave of Brandenburg, over the possession of lower Lusatia, was taken prisoner. Surrendering lower Lusatia he was released, but it was only at Wurtzau's death in 1339 that Frederick gained possession of Meissen. Frederick, who was named the Peaceful, died in 1333 and was followed as margrave by his son Frederick II., called the Grave, who added several counties to his inheritance. From this latter Frederick's death in 1349 until 1381 the lands of the family were ruled by his three sons jointly; but after the death of his eldest son Frederick III. in 1381 a division was made by which Meissen fell to his youngest son William I. In 1407 William was succeeded by his nephew Frederick, called the Warlike, who in 1423 received from the emperor Sigismund the electoral duchy of Saxe-Wittenberg. The mark then became merged in the duchy of Saxon, and at the partition of 1485 fell to the Albertine line. As Meissen was relieved from the attacks of the Slavs by the movement of the German boundary to the east, its prosperity increased. Many towns were founded, among which were Dresden, Leipzig and Freiburg; Chemnitz began its textile industry; and although the condition of the peasants was wretched, that of the towns men was improving. The discoveries of silver brought great wealth to the margraves, but they resorted at times to beds, which were contributions from the nobles and ecclesiastics who met in a kind of diet. William's death in 1447 left the mark of Meissen to lay on both banks of the Elbe, and stretched from Bohemia to the duchy of Saxe-Wittenberg, embracing an area of about 3000 sq. m.

MEISSONIER, JEAN LOUIS EUSTACE (1815-1891). French painter, was born at Lyons on the 21st of February 1815. From his schooldays he showed a taste for painting, to which some early sketches, dated 1823, bear witness. After being placed with a druggist, he obtained leave from his parents to become an artist, and, owing to the recommendation of a painter named Potier, himself a second class Prix de Rome, he was admitted to Léon Cogniet's studio. He paid short visits to Rome and to Switzerland, and exhibited in the Salon of 1831 a picture then called "Les Bourgeois Flamands"("Dutch Burgers"), but also known as "The Visit to the Burgomaster," subsequently purchased by Sir Richard Wallace, in whose collection (at Hertford House, London) it is, with fifteen other examples of this painter. It was the first attempt in France in the particular genre which was destined to make Meissonier famous: microscopic painting—miniature in oils. Working hard for daily bread at illustrations for the publishers—Curmer, Hetzel and Dubocher—he also exhibited at the Salon of 1836 the "Chess Player" and the "Errand Boy." After some not very happy attempts at religious painting, he returned, under the influence of Chenavard, to the class of work he was born to excel in, and exhibited with much success the "Game of Chess" (1841), the "Young Man playing the 'Cello"" (1842), "The Painter in his Studio" (1843), "The Guard Room," "The Young Man looking at Drawings," "The Game of Piquet" (1845), and the "Game of Bowls"—works which show the finish and certainty of his technique, and assured his success. After his "Soldiers" (1848) he began "A Day in June," which was never finished, and exhibited "A Smoker" (1849) and "Bravos" ("Les Bravi," 1852). In 1853 he touched the highest mark of his achievement with "The Gamblers," and then exhibited ("La Rixe"), which was presented by Napoleon III. to the English Court. His triumph was sustained at the Salon of 1857, when he exhibited nine pictures, and drawings; among them the "Young Man of the Time of the Regency," "The Painter," "The Shoeing Smith," "The Musician," and "A Reading at Diderot's." To the Salon of 1861 he sent "The Emperor at Solferino," "A Shoewing Smith," "A Musician," "A Painter," and "M. Louis Fould"; to that of 1864 another version of "The Emperor at Solferino," and "1814." He exhibited regularly from 1861 to 1877. A "Gambler" (1873), and his "Desaix and the Army of the Rhine" (1876), Meissonier worked with elaborate care and a scrupulous observation of nature. Some of his works, as for instance his "1825," remained ten years in course of execution. To the great Exhibition of 1878 he contributed sixteen pictures: the portrait of Alexandre Dumas which had been seen at the Salon of 1877, "Cuirassiers of 1805," "A Venetian Painter," "Moreau and his Staff before Hohenlinden," a "Portrait of a Lady," the "Road to La Saliche," "The Two Friends," the "Outpost of the Grand Guard," "A Scout," and "Dicing his Memoirs." Thenceforward he exhibited less in the Salons, and sent his smaller works to smaller exhibitions. Being chosen president of the Great National Exhibition in 1883, he was represented there by such works as "The Pioneer," "The Army of the Rhine," "The Arrival of the Guests," and "Saint Mark." On the 24th of May 1884 an exhibition was opened at the Petit Gallery of Meissonier's collected works, including 146 examples. As president of the jury on painting at the Exhibition of 1885 he contributed some new pictures. In the following year the New Salon was formed (the National Society of Fine Arts), and Meissonier was president. In the exhibition in 1886 he exhibited in 1887 he was colonel of a marching regiment. In 1840 he was awarded a third-class medal, a second-class medal in 1841, first-class medals in 1843 and 1844 and medals of honour at the great exhibitions. In 1846 he was appointed knight of the Legion of Honour and promoted to the higher grades in 1856, 1867 (June 29), and 1880 (July 12), receiving the Grand Cross in 1889 (Oct. 29). He nevertheless cherished certain ambitions which remained unfulfilled. He hoped to become a professor at the École des Beaux Arts, but the appointment he desired was never given to him. On various occasions,
MEISSONIER, J. A.—MEKONG

eighty, as he desired to be chosen deputy or made senator, but he was not elected. In 1861 he succeeded Abel de Pujol as member of the Academy of Fine Arts. On the occasion of the centenary festival in honour of Michangelo in 1871 he was the delegate of the Institute of France to Florence, and spoke as its representative. Meissonier was an admirable draughtsman upon wood, his drawings to Les Contes Rémains (engraved by Lavoignat), to Lamartine’s Fall of an Angel, to Paul and Virginia, and to The French Painted by Themselves being among the best known. The leading engravers and etchers of France have been engaged upon plates from the works of Meissonier, and many of these plates command the highest esteem of collectors. Meissonier died in Paris on the 21st of January 1861. His son, Jean Charles Meissonier, also a painter, was his father’s pupil, and was admitted to the Legion of Honour in 1886.

MEISSONIER, JUSTE AURÉLE (1605-1750), French goldsmith, sculptor, painter, architect, and furniture designer, was born at Turin, but became known as a worker in Paris, where he died. His Italian origin and training were probably responsible for the extravagance of his decorative style. He was shared, and perhaps distanced, the fabulously curious designs of Oppenard and Gérard, since he dealt with the Baroque in its most daring and flamboyant developments. Rarely does he leave a foot or two of undecorated space; the effect of the whole is futile and fatiguing. It was because Meissonier carried the style of his day to its extreme that he acquired so vast a popularity. Like the English brothers Adam at a later date he not only as architect built houses, but as painter and decorator covered their internal walls; he designed the furniture and the candlesticks, the silver for the decanters for the table; he was ready to produce a snuff-box as a watch case or a sword hilt. Not only in France, but for the nobility of Poland, Portugal and other countries who took their fashions and their taste from Paris, he made designs, which did nothing to improve European taste. Yet his achievement was not wholly without merit. His work in gold and silver-plate was often graceful and sometimes bold and original. He was least successful in furniture, where his twirls and convolutions, his floral and rocaille motives were conspicuously offensive. He was appointed by the XV. Destinataire de la chambre et du cabinet du roi; the post of designer for les pommes humbres et galantes was also held along with that of Orfevre du roi.

For our knowledge of his work we are considerably indebted to his own books of design: Livre d’ornements en trente pièces; Livre d’orfèvrerie d’église en six pièces, and Ornements de la carte chronologique.

MEISTERSINGER (Ger. for “master-singer”), the name given to the German lyric poets of the 14th, 15th and 16th centuries, who carried on and developed the traditions of the medieval Minnesingers (q.v.). These singers, who, for the most part, belonged to the artisan and trading classes of the German towns, regarded as their masters and the founders of their guild twelve poets of the Middle High German period, among whom were Wolfram von Eschenbach, Konrad von Würzburg, Reinmar von Zweter and Frauenlob. The last mentioned of these, Frauenlob, is said to have established the earliest Meistertum school at Mainz, early in the 14th century. It is only a traditional belief, but the institution of such schools originated undoubtedly in the upper Rhine district. In the 14th century there were schools at Mainz, Strassburg, Frankfurt, Würzburg, Zürich and Prague; in the 15th at Augsburg and Nuremberg, the last becoming in the following century, under Hans Sachs, the most famous of all. By this time the Meistertum schools had spread all over south and central Germany; and isolated guilds were to be found farther north, at Magdeburg, Breslau, Götitz and Danzig.

Each guild numbered various classes of members, ranging from beginners, or Schuler (corresponding to trade-apprentices), to Schulfreunde (who were equivalent to Gesellen or journey- men), to Meister, a Meister being a poet who was not merely able to write new verses to existing melodies but had himself invented a new melody. The poem was technically known as a Bar or Gesetz, the melody as a Ten or Weis. The songs were all sung in the schools without accompaniment. The rules of the art were set down in the so-called Weisbuch or law-book of the guild. The meetings took place either in the Rathaus, or town hall, or sometimes they were held—as was usually the case—on Sunday, in the church; and three times a year, at Easter, Whitsuntide and Christmas, special festivals and singing competitions were instituted. At such competitions or Schulsingen judges were appointed, the so-called Merker, whose duty it was to criticize the competitors and note their offences against the rules of the Tabulatur.

The literary value of the Meistertum poetry was hardly in proportion to the large part it played in the life of the German towns of the 13th and 16th centuries. As the medieval lyric decayed, more and more of the Meistertum was given to the externals of composition, the form, the number of syllables, the melody; and it was such externals that attracted the interest of these burgher-poets. Poetry was to them a mechanical art that could be learned by diligent application, and the prizes they had to bestow were the rewards of ingenuity, not of genius or inspiration. Consequently we find an extraordinary development of strophic forms corresponding to the many new “tones” which every Meister singer regarded it as his duty to invent—tones which have the title of his region and often ridiculous names, such as Gestreiftsafränklium, Gebelachsweis, geklammte Paradiesweis, &c. The verses were adapted to the musical strophes by a merely mechanical counting of syllables, regardless of rhythm or sense. The meaning, the sentiment, the thought, were the last things to which the Meistersingers gave heed. At the same time there was a certain healthy aspect in the cultivation of the Meistertum among the German middle classes of the 15th and 16th centuries; the Meister singer, if not great or even real poetry, had—especially in the hands of a poet like Hans Sachs—many germ of promise for the future. It reflected without exaggeration the burgher’s desire to venerate the faith of the German burgher, his blunt good sense and honesty of purpose. In this respect it was an important factor in the rise of that middle-class literature which found its most virile expression in the period of the Reformation. The Meistertum reached its highest point in the 16th century; and it can hardly be said to have outlived that epoch, although the traditions of the Meistersinger schools lingered in south German towns even as late as the 17th century.

Specimens of Meistersinger poetry will be found in various collections, such as J. J. Göhres, Altdutsche Volks- und Meistersäge (1817); K. Bartsch, Meistersdigter der Kolmter Houndtschrift (Publ. of the Stuttgart Literarischer Verein, vol. xvii.; 1862). Of the older sources of information about the Meistersinger the most important are Adam Puschmann’s Lindner Bericht der deutschen Meistersagens zusammen der Tabulatur (1571; reprinted in W. Braune’s Neudrucke deutscher Literaturwercke of the 16. and 17. Jahrh., 75, 1888), and J. C. Wagonsel, Die cirte der Norddeutschen Meistersagen (Leipzig, 1815). The first important works on the subject are: J. K. Schnorr von Carolsfeld, Zur Geschichte der deutschen Meistersagens (1872); R. von Lilienron, Über den Inhalt der allgemeinen Bildung in der Zeit der Scholastik (1876); G. Jacobsthal, “Die musikalische Bildung der Meistersinger” (Zeitschrift für deut. Altermu., xx.; 1876); O. Lyon, Minne- und Meistersage (1882); K. Mey, Der Meistersinger in Geschichte und Kunst (1892). The art of the Meistersingers has been described by Richard Wagner in his music drama Die Meistersinger (1868).

MEKONG, or ME NAM KONG (pronounced Kâawm), sometimes known as the Cambodin River, the great river of Indo-China, having its origin in the Tibetan highlands. It is the third or fourth longest river in Asia and the seventh or eighth in the world. It is about 2800 m. in length, of which 1200 flow through portions of the Chinese Empire and Tibet and 1600 through French territory. Its sources are not definitely settled, but it is supposed to rise on the slopes of Dza-Nag-Lung-Mung in about
MELA—MELampus

33° N., 93° E., at an altitude of 16,700 ft. above sea-level. Throughout the greater part of its course in Tibet, where it is called the Dza-Chu, it flows south-eastwards to Chiamdo, on the great east and west caravan route from China to Lhasa. At this point it is about 10,000 ft. above sea-level. From here it flows southwards through little-known mountain wastes. Below Dayul in lat. 29° it is known by the Chinese name of Lantsang Kiang. For the next 300 m. of its course the Lantsan Kiang, or the high town, is in the hands of the Tibetans inhabiting its rugged valley, the Mekong, is very little known to us. The river flows beneath bare and rocky walls. A few scattered villages of Lusus and Missos exist in this region, but no trade from north to south. In 25° 18' N. the Tali-Bhamo caravan route, described by Colborne Baker, crosses the river by one of those iron suspension bridges which are a feature of Yun-nan, at a height of 4,700 ft. above sea-level. From this point to Chiang or Keng Hung, the head of the old confederacy of the Sibsawng Fanna or Twelve States, it is little known; the fact that it falls some 900 ft. for each degree of latitude indicates the character of the river. Under the provisions of the Anglo-French agreement of January 1896, from the Chinese frontier southwards to the mouth of the Nam Hok the Mekong forms the frontier between the British Shan States on the west and the territories acquired from Siam by France in 1893. By the treaty of 1893, from that point southwards to about 13° 30' N. it is also the frontier between French Indo-China and Siam, and a zone extended 25 kilometres inland from the right bank, within which the Siamese government agreed not to construct any fortified port or maintain any armed force. This 25 kilometres zone is the French domain of Chantaburi, the provincial capital of the French province of Chantaburi, which is on the left bank of the Mekong. Below the Siamese town of Chiang Sen the river takes its first great easterly bend to Luang Prabang, being joined by some important tributaries. This portion is obstructed by rapids. The country is mountainous, and the vegetation of the lower heights begins to assume a tropical aspect. From Luang Prabang the river cuts its way southwards for two degrees through a lonely jumble country among receding hills of low elevation. From Chiang Khan the river again turns eastwards along the 18th parallel, forcing its way through its most serious rapid-barrier, and receiving some important tributaries from the highlands of Tung Chiem Kung and Chiang Kwang, the finest country in Indo-China. In 104° E. the river resumes a southerly course through a country thinly peopled. At Kemarat (106° N.) the fourth serious rapid-barrier occurs, some 60 m. in length, and the last at Khong in 14° N. From here to its outfall in the China Sea the river winds for some 400 m. through the French territories of Cambodia and Cochinchina, and to its annual overflow these country owe their extraordinary fertility. The French have done much to render the river navigable. Steamers ply regularly from Saigon through Mytho to Pnompenh, and launches proceed from this place, the capital of Cambodia, to the Preapatan rapids, and beyond this a considerable portion of the distance to Luang Prabang, the journey being finished in native boats. (J. G. Sc.)

MELA, POMPONIUS (fl. c. a.d. 43), the earliest Roman geographer. His little work (De situ orbis libri IIII) is a mere compendium, occupying less than one hundred pages of ordinary print, dry in style and deficient in method, but of pure Latinity, and occasionally relieved by pleasing word-pictures. Excepting the geographical parts of Pliny's Historia Naturalis (where Mela is cited as an important authority) the De situ orbis is the only formal treatise on the subject in classical Latin. Nothing is known of the author except his name and birthplace—the small town of Tingentera or Cingentera in southern Spain, on Algeciras Bay (Mela ii. 6, § 96; but the text is here corrupt). The date of his writing may be approximately fixed by his allusion (iii. 6 § 49) to a proposed British expedition of the reigning emperor, almost certainly that of Claudius in a.d. 43. That this passage cannot refer to Julius Caesar is proved by several references to events of Augustus's reign, especially to certain new names given to Spanish towns. Mela has been without probability identified by some with L. Annaeus Mela of Corduba, son of Seneca the rhetorician, and brother of the great Seneca.

The general views of the De situ orbis mainly agree with those current among Greek writers from Eratosthenes to Strabo; the extraordinary feature is that Mela, but Pomponius Mela, among ancient geographers in that, after dividing the earth into five zones, of which two only were habitable, he asserts the existence of habitable zones, inhabiting the southern temperate and the next to the folk of the northern temperate regions from the unbearable heat of the intervening torrid belt. On the divisions and boundaryslines of Europe, Asia and Africa, he repeats Eratosthenes; like all other geographers of his day under the influence of Eratosthenes, he regards the Caspian Sea as an inlet of the Northern Ocean, corresponding to the Persian and Arabian (Red Sea) gulfs on the south. His Indian conceptions are inferior to those of some earlier Greek writers; he appears to have supposed the great Indian seas to occupy the south-eastern angle of Asia, whence the coast trended northwards to Scythia, and then swept round westward to the Mediterranean, where he places the Hesperian Mountains and the Hyperboreans near the Scythian Ocean. In western Europe his knowledge (as was natural in a Spanish subject of Imperial Rome) was somewhat in advance of the Greek geographers. He defines the North Sea, the coast-line of Holland and of the British Channel Bay of Biscay more accurately than Eratosthenes or Strabo, his ideas of the British Isles and their position are also clearer than Strabo's. He sometimes affects to name the Orcades or Orkneys, which he defines and locates pretty correctly. Of northern Europe his knowledge was imperfect, but he speaks vaguely of a great bay ("Codanus sinus") to the north of Germany, among whose many islands he places one, "Oland," which reappears in Pliny as "Scandinavia." Mela's descriptive method is peculiar and inconvenient. Instead of treating each continent separately he begins at the Straits of Gibraltar, and describes the countries adjoining the south coast of the Mediterranean; then he moves round by Syria and Asia Minor to the Black Sea, and so returns to Spain along the north shore of the Euxine, Propontis, &c. After treating the Mediterranean islands, he goes round the ocean littoral—west to north, east and south successively—from Spain and Gaul round to India, from India to Persia, Arabia and Ethiopia; and so again works back to Spain round south Africa. Like most classical geographers he ever considered the Danubian Continent as surrounded by sea and not extending very far south.

The first edition of Mela was published at Milan in 1477; the first good edition was by Vadianus (Basel, 1522), superseded by those of Voss (1628), J. Gronovius (1685 and 1696), A. Gronovius (1722 and 1728), and Tschuschev (1806-1807), in seven parts (Leipzig; the most elaborate of all); G. Parthey's (Berlin, 1867), gives the best text. The English translation by Arthur Golding (1586), is famous; see also E. H. Bunbury, Ancient Geography, ii. 352-368, and D. Detlefsen, Quellen und Forschungen zur alten Gesch. und Geogr. (1906).

(M. B. K.; C. R. B.)

MELACONITE, a mineral consisting of cupric oxide, CuO, and known also as black copper ore. In appearance it is strikingly different from cuprite (c.v) or red copper ore, which is cuprous oxide. Crystals are rare; they belong to the monoclinic, or possibly to the anorhctic system, and have the form of thin triangular or hexagonal scales with a steel-grey colour and brilliant metallic lustre. More often the mineral is massive, earthy or pulverulent, and has a dull iron-black colour. Hence the name melacinite, from the Greek μελας, black and κόπης, dust, which was originally given by F. S. Beudant in 1832 in the form melacine. The crystalized Vesuvian mineral was later named tenorite, a name commonly adopted for the species. The hardness of the crystals is 3-4, but the earthy and powdery forms readily soil the fingers; the spec. grav. is 5-9. Crystals have been found only at Mt Vesuvius, where they encrust lava, and at Cornwall. The other forms of melacinite are common in copper mines, and have resulted by the alteration of chalcolite, chalcopyrite and other copper ores, on which they often form a superficial coating. (L. J. S.)

MELAMPUS, in Greek legend, a celebrated seer and physician, son of Amythaon and Eidomene, brother of Bias, mythical eponymous hero of the family of the Melampodidse. Two young serpents, whose life he had saved, licked his ears while he slept, and from that time he understood the language of birds and beasts. In the art of divination he received instruction from Apollo himself. To gain the consent of Neucus, King of Pylus, to the marriage of his daughter Pero with Bias, Melampus
undertook to obtain possession of the oxen of the Thessalian prince Iphicus. As Melampus had foretold, he was caught and imprisoned, but was released by Phylacus (the father of Iphicus) on giving proof of his powers of divination, and was finally presented with the oxen as a reward for having restored the virility of the son. Melampus subsequently obtained a share in the kingdom of Argos in return for having cured the daughters of its king Proetus, who had been driven mad for offering resistance to the worship of Dionysus or for stealing the gold from the statue of Heracles. At Aegosthena in Megara there was a sanctuary of Melampus, and an annual festival was held in his honour. According to Herodotus, he introduced the cult of Dionysus into Greece from Egypt, and his name ("black foot") is probably "a symbolical expression of his character as a Bacchic propitiatory priest and see" (P弛sch). According to the traditional explanation, he was so called from his foot having been tanned by exposure to the sun when a boy. In his character of physician, he was the reputed discoverer of the herb melampodium, a kind of belladone. Melampus and Bias are symbolical representatives of cunning and force.  

See Apollodorus i. 9, 11, 12; ii. 2, 2; Odyssey, xv. 225-240; Diod. Sic. iv. 68; Herodotus ii. 49; iv. 34; Pausanius ii. 18, 4; iv. 36, 3; scholar on Theocritus iii. 43; Ovid, Metam. x. 325; C. Eckermann, Melampus und sein Geschicht (1840). Melampus is also the name of the author of a short treatise of little value on Divination by means of Pulpitation (Παλπατίαν και Βιομετρίαν). It probably dates from the time of Tolemy Philalethius (3rd cent. a. C.) Edition by J. G. Franz in Scipriores physiognomiae veteres (1780).

**MELANCHLAENI** (from Gr. μελανός, and χάλαυν, "Black-cloaks"), an ancient tribe to the north of Scythia, probably about the modern Ryazan and Tambov (Herodotus iv. 106). They have been identified with the Finnish tribes Merja (now extinct) and Cheremis, now driven north-east on to the middle Volga. These, till recently, wore black. There has been confusion between this tribe and another of the same name mentioned by Pliny (N. H. vi. 15), and Tolemy in the Caucasus.

**MELANCHOLY** (Gr. μελανόγχολα, from μελανός, black, and χόλη bile), originally a condition of the mind or body due to a supposed excess of black bile, also this black bile itself, one of the chief "humours" of the body, which were, according to medieval physiology, blood, phlegm, choler and melancholy (see HUMOUR); now a vague term for desponding grief. From the 17th century the term was also used of the medical disease now known as "melancholia" (see INSANITY), but without any reference to the supposed cause of it.

**MELANCHTHON, PHILIPP** (1497-1560), German theologian and reformer, was born at Bretten in Baden on the 16th of February 1497. His father, George Schwartzard, was an armorer under the Palatinate princes. His mother, Barbara Reuter, a niece of Johann Reuchlin, was shrewd, thrifty and affectionate. Her father, Johann Reuter, long burgomaster of Bretten, supervised the education of Philipp, who was taught first by Johannes Hynacius and then by Georg Simler at the academy of Pforzheim. Reuchlin took an interest in him, and, following a contemporary custom, named him Melanchthon (the Greek form of Schwartzard, black earth). In October 1529 he went to Heidelberg, where he took the B.A. degree, afterwards proceeding M.A. at Tübingen. The only other academic distinction he accepted was the B.D. of Wittenberg (1519). He would never consent to become a "doctor," because he thought the title carried with it responsibilities to which he felt himself unequal. At Tübingen he lived as student and teacher for six years, until on Reuchlin's advice, the elector of Saxony called him to Wittenberg as professor of Greek in 1518.

1 Her character is evidenced by the familiar proverb—  
Wor der mehr will verzehren  
Denn sein Pfing kann erheben,  
Der muss zuletzt verderben  
Bisher nicht am besten—  
"Of which Melanchton said to his students "Didici hoc mea matre, vos etiam observe." (For Melanchthon's Latin version of the saying see Corpus reformatorum, x. 469.)

This appointment marked an epoch in German university education; Wittenberg became the school of the nation; the scholastic methods of instruction were set aside, and in a Discourse on Reforming the Studies of Youth Melanchthon gave proof, not only that he had caught the Renaissance spirit, but that he was fitted to become one of its foremost leaders. He began to lecture on Homer and the Epistle to Titus, and in connection with the former he announced that, like Solomon, he sought Tyrian brass and gems for the adornment of God's Temple. Luther received a fresh impulse towards the study of Greek, and his translation of the Scriptures, begun as early as 1517, now made rapid progress, Melanchthon helping to collate the Greek versions and revising Luther's translation. Melanchthon felt the spell of Luther's personality and spiritual depth, and seems to have been prepared on his first arrival at Wittenberg to accept the new theology, which as yet existed mainly in subjective form in the person of Luther. To reduce it to an objective system, to exhibit it dialectically, the calmer mind of Melanchthon was requisite.

Melanchthon was the first drawn into the arena of the Reformation controversy through the Leipzig Disputation (June 27—July 8, 1519), at which he was present. He had been reproved by Johann Eck for giving aid to Carlstadt ("Tace tu, Philippus, ac tua studia cura nec perturba"), and he was shortly afterwards himself attacked by the great papal champion. Melanchthon replied in a brief and moderately worded treatise, setting forth at length the first principles of the supreme authority of Scripture in opposition to the doctrines with which Melancrath had been acquainted. His marriage in 1520 to Catharine Krapp of Wittenberg gave a domestic centre to the Reformation. In 1521, during Luther's confinement in the Wartburg, Melanchthon was leader of the Reformation cause at the university. He defended the action of Carlstadt, when he dispensed the Eucharist in an "evangelical fashion."

With the arrival of the Anabaptist enthusiasts of Zwickau, he had a more difficult task, and appears to have been irresolute. Their attacks on infant baptism seemed to him not altogether irrational, and in regard to their claim to personal inspiration he said "Luther alone can decide; on the one hand let us beware of quenching the Spirit of God, and on the other of being led astray by the spirit of Satan." In the same year, 1521, he published his Loci communes rerum theologicae, the first systematic presentation of the reformed theology. From 1522 to 1524 he was busy with the translation of the Bible and in publishing commentaries. In 1524 he went for reasons of health into southern Germany and was urged by the papal legate Campeggi to renounce the new doctrines. He refused, and maintained his refusal by publishing his Summa doctrinae Lutherti.

After the first Diet of Spires (1526), where a precarious peace was patched up for the reformed faith, Melanchthon was deputed as one of twenty-eight commissioners to visit the reformed states and regulate the constitution of churches, he having just published a famous treatise called the Libelli visitatorii, a directory for the use of the commissioners. At the Marburg conference (1526) between the German and Swiss reformers, Luther was pitted against Oecolampadius and Melanchthon against Zwingli in the discussion whether or not there was an external sacrament. How far the normally conciliatory spirit of Melanchthon was here biased by Luther's intolerance is evident from the exaggerated accounts of the conference written by the former to the elector of Saxony. He was at this time even more embittered than Luther against the Zwinglians. At the Diet of Augsburg (1530) Melanchthon was the leading representative of the reformation, and it was he who prepared for that diet the seven-teen articles of the Evangelical faith, which are known as the "Augsburg Confession." He held conferences with Roman divines appointed to adjust the differences, and afterwards wrote an Apology for the Augsburg Confession. After the Augsburg
conference further attempts were made to settle the Reformation controversy by a compromise, and Melanchthon, from his conciliatory spirit and facility of access, appeared to the defenders of the old faith the fittest of the reformers to deal with. His historical instinct led him ever to revert to the original unity of the church, and to regard subsequent errors as excrescences rather than proofs of an essentially anti-Christian system. He was weary of the rubies theologorum, and dreamed that the evangelical leaven, if tolerated, would purify the church’s life and doctrine. In 1537, when the Protestant divines signed the Lutheran Articles of Schmalkalden, Melanchthon appended to his signature the reservation that he would adhere to a pacific provision he provided he allowed the gospel and did not claim to rule by divine right.

The year after Luther’s death, when the battle of Mühlberg (1547) had given a seemingly crushing blow to the Protestant cause, an attempt was made to weld together the evangelical and the papal doctrines, which resulted in the compilation by Pflug, Sidonius and Agricola of the Augsburg “Interim.” This was proposed to the two parties in Germany as a provisional ground of agreement till the decision of the Council of Trent. Melanchthon, on his part, was forced to swerve from the views set forth in the Loci communis; but he regarded the surrender of more perfect for less perfect forms of truth or of expression as a painful sacrifice rendered to the weakness of erring brethren. Luther, though he had probably uttered in private certain expressions of dissatisfaction with Melanchthon, maintained unbroken friendship with him; but after Luther’s death certain smaller men formed a party emphasizing the extremest points of his doctrine. Before the later years of Melanchthon were over, occupied with controversies within the Evangelical church, and fruitless conferences with his Romanist adversaries. He died in his sixty-third year, on the 19th of April 1560, and his body was laid beside that of Martin Luther in the Schlosskirche at Wittenberg.

His ready pen, clear thought and elegant style, made him the scribe of the Reformation, most public documents on that side being drawn up by him. He never attained entire independence of Luther, though he gradually-modified some of his positions from those of the pure Lutheranism with which he set out. His development is chiefly noteworthy in regard to these two leading points—the relation of the Evangelium or doctrine of free grace (1) to free will and moral ability, and (2) to the law and poenitentia or the good works connected with repentance. At first Luther’s cardinal doctrine of justification appealed to him in the same spirit with any view of free will; and, following Luther, he renounced Aristotle and philosophy in general, since “philosophers attribute everything to human power, while the sacred writings represent all moral power as lost by the fall.” In the first edition of the Loci (1527) he held, to the length of fatalism, the Augustinian doctrine of irremissible grace, working according to God’s immutable decrees, and denied freedom of will in matters civil and religious alike. In the Augsburg Confession (1530), which was largely due to him, freedom is claimed for the will in non-religious matters, and in the Loci of 1533 he calls the denial of freedom Stoicism, and nowhere accepts the Augustinian justification there is a human cause. But this was not worthiness, in the recipient, subordinate to the Divine causality. In 1535, combating Laurentius Valla, he did not deny the spiritual incapacity of the will per se, but held that this is strengthened by the very power of God, to which it can cleave. The will co-operates with the word and the Holy Spirit. Finally, in 1543, he says that the cause of the difference of final destiny among men lies in the different method of treating grace which is possible to believers as to others. Man may pray for help and reject grace. This he calls free will, as the power of laying hold of grace. Melanchthon’s doctrine of the three concurrent causes in conversion, viz. the word, the work of grace, and the will, is one of the best conceptions of Pelagian position called Synergism, which was held by some of his immediate followers. Still toward the relation of grace to repentance and good works, Luther was disposed to make itself comfortable to accommodate. Melanchthon, however, for whom ethics possessed a special interest, laid more stress on the law. He began to do this in 1527 the Liber scholasticus urging the urgent need to instruct their people in the necessity of repentance, and to bring a clear understanding of the law to bear upon men in order to faith. This brought down upon him the opposition of the Antinomian Johannes Agricola. In the year of 1532 he passed the Loci absolutae sacrae doctrinae in co-existence of justification and good works in the believer on a secure basis by declaring the latter necessary to eternal life, though believer’s destiny thereto is already fully guaranteed in his justification. In the Loci of 1543 he did not retain the doctrine of the necessity of good works in order to salvation, and to this he added, in the Leipzig Interim, “that this in no way countenances the law and moral ideas; but that the relation of the law and good works is never clearly brought out by him, and he at length (in the year 1544) distinctly renounced the Augustinian inheritance of bliss in and by Christ alone, and that good works are used as a means or by reason of immutable Divine command.

MELANESIA, the principal works of Melanchthon, with the bulk of his correspondence, are contained in the Corpus reformatorum (vols. i.–xxviii.; Halle, 1834–1850), edited by Bretschneider and Bindseil, to which must be added Bindseil’s Supplement (2 volumes, 1851–1855) and five volumes of G. F. Martini of Melanchthon’s correspondence with his friend Joachim Camerarius (1860), a new annotated edition of which is much needed. The best modern life is that by Georg Ellinger (Berlin, 1892); next is that of Karl Schmidt (Elberfeld, 1861). The celebration in 1887 of the 400th anniversary of Melanchthon’s birth produced many short biographies and Festreden, among them works by J. W. Richard (New York and London, 1898); Richard Rothe’s (London, 1897); Karl Sell (Halle, 1897); Ferdinand Cohrs (Halle, 1897); Beyeclagh and Harrack (1898): and Rothe’s Festrede (1896) also is good. The most learned of modern Melanchthon scholars was probably Karl Hartfelder, who wrote Die Schriften des Melanchthon als Predecessor Germaniae (Berlin, 1890), Melanchthoniana paediagica (Leipzig, 1892), giving in the first named two full bibliographies, one of all works written on Melanchthon, the other of all works written by him (in chronological order). The reader believed that a good deal of unpublished material is still left in German and foreign libraries. Thus three long unknown letters are published in the Quellen und Forschungen der König. Univers.Inst. Hist. at Romdahl vol. iv. edited by the Cardinal of Augsburg and one to Lazarus von Schwendi. Thus Melanchthon’s correspondence on his way to the Council of Trent as delegate of the elector of Saxony and the cardinal had offered to meet him at Dillingen. He is one of the dominating personalities of the Reformation, but was not a national synod, which would have been a better means of arriving at the truth.

MELANESIA, one of the three great divisions of the oceanic islands in the central and western Pacific. It embraces the Bismarck Archipelago, N. E. of New Guinea, the Louisiade, Solomon, Santa Cruz, New Hebrides and Loyalty islands, New Caledonia, Fiji and intervening small groups. The name (Gr. melanos, black, and oineus, island) is derived from the black colour of the prevailing native race, the Papuan and its allied tribes. Many of these differ widely from the parent race, but all the Melanesian peoples have certain common characteristics which distinguish them sharply from the inhabitants of Polynesia and Micronesia. Their civilization is lower. The Melanesians are mostly "negroid," nearly black, with crisp, curly hair elaborately dressed; their women hold a much lower position than among the Polynesians; their institutions, social, political and religious, are simpler, their manners ruder; they have few moral principles; they are much given to gambling; but they are universal; but their artistic skill and taste, as with some of the lower African negroes, are remarkable, and they are amenable to discipline and fair treatment. Their languages, which exhibit considerable difference among themselves, have features which mark them off clearly from the Polynesians, notwithstanding certain fundamental relations with the latter.

See R. H. Codrington, The Melanesian Languages (Oxford, 1885) and The Melanesians (Oxford, 1891); the articles—Papuans and Pacific Ocean; also those on the several island-groups, &c.

1It must be admitted, however, that Matthias Flacius saved the Reformation.
MELANTHUS, a noted Greek painter of the 4th century B.C. He belonged to the school of Scyion, which was noted for fine draughtsmanship.

MELBA [NELLIE PORTER ARMSTRONG] (1859— ), British operatic soprano, née Nellie Porter Mitchell, was born at Burnley, near Melbourne, Australia, her father being a contractor, of Scottish blood. She sang at a local concert when six years old, and was given a good musical education. In 1882 she married Captain Charles Armstrong, and in 1886 went to study singing in Paris under the famous teacher, Madame Mathilde Marchesi, whose daughter, Madame Blanche Marchesi, also was a famous singer. In 1887 she made her début in opera at the Opéra Comique, taking the stage-name of Madame Melba from her connexion with Melbourne. In the next year she sang the part of Lucia, which remained one of her famous rôles, at Covent Garden, London; and, though critics complained of her coldness as an actress, her liquid voice and brilliant execution henceforth made her famous as the greatest successor to Patti, in pure vocalization, on the operatic stage. She maintained this position for over twenty years, her triumphs being celebrated in every country.

See W. McC. Torens, Memoirs of Lord Melbourne (1878); Lloyd Sanders, Lord Melbourne's Papers (1886); A. Hayward's essay (from the Quarterly Review, 1879) in "Eminent Statesmen" (1886).

MELBOURNE, the capital of Victoria, and the most populous city in Australia. It is situated on Hobson's Bay, a northern bend of the great harbour of Port Phillip, in Bourke county, about 500 miles south-west of Sydney. The suburbs extend along the shore of the bay for more than 10 miles, but the part distinctively known as the "city" occupies a site about 3 miles inland on the north bank of the Yarra river. The appearance of Melbourne from the sea is by no means picturesque. The busy shipping suburbs of Port Melbourne and Williamstown occupy the flat alluvial land at the mouth of the Yarra. But the city itself has a different aspect; its situation is relieved by numerous gentle hills, which show up its fine public buildings to great advantage; its main streets are wide and well kept, and it has an air of prosperity and comfort. The term "city" occupies two hills, and along the valley between them runs the thoroughfare of Elizabeth Street. Parallel to this is Swanston Street, and at right angles to these, parallel to the river, are Bourke Street, Collins Street and Flinders Street—the first being the busiest in Melbourne, the second the most fashionable with the best shops, and the third, which faces the river, given up to the maritime trade. These streets are an eighth of a mile apart, and between each is a narrower street bearing the name of the wider, with the prefix "Little." The original plan seems to have been to construct these narrow streets to give access to the great business houses which, it was foreseen, would be built on the frontage of the main streets. This plan, however, miscarried, for space grew so valuable that large warehouses and business establishments have been erected in these lanes. Little Flinders Street, in which the great importers' warehouses are mainly situated, is locally known as "the Lane." In the centre of the city some of the office buildings are ten, twelve or even fourteen storeys high. The main streets are 90 ft. wide, and the lanes somewhat less than half that width. Round the city lies a circle of populous suburbs—"the north-east Fitzroy" (pop. 31,689) and Collingwood (32,749), to the east Richmond (37,824), to the south-east Prahran (40,441), to the south South Melbourne (40,610), to the south-west Port Melbourne (12,176), and to the north-west North Melbourne (18,120). All these suburbs lie within 3 m. of the general post office in Elizabeth Street; but outside them and within the 5 m. radius is another circle—to the east Kew (3469) and Hawthorne (21,430), to the south-east St Kilda (20,342) and Brighton (19,047), to the south-west Williamstown (14,025) and Footscray (18,318), to the north-west Essendon (17,426), and to the north Brunswick (24,141). Numerous small suburbs fill the space between the two circles, the chief being Northcote, Preston, Camberwell, Toorak, Caulfield, Elsternwick and Coburg. Some of these suburbs are independent cities, others separate municipalities. In spite of the value of land, Melbourne is not a crowded city.

The Parliament House, standing on the crown of the eastern hill, is a massive square brick building with a pillared freestone portico approached by a broad flight of steps. The interior is lavishly decorated and contains, besides the legislative chamber, a magnificent library of over 50,000 volumes. At the top of
Collins Street a building in brown freestone is occupied by the Treasury, behind which and fronting the Treasury Park another palatial building houses the government offices. A little further on is St Patrick’s Roman Catholic cathedral, the seat of the archbishop of Melbourne, a building of somewhat sombre blue-stone. The free-standing churches face each other in Collins Street, the Scots church, a Gothic edifice with a lofty spire, and the Independent church, a fine Saracenic building with a massive campanile. The seat of the Anglican bishop, St Paul’s cathedral, has an elegant exterior and a wealth of elaborate workmanship within, but stands low and is obscured by surrounding warehouses. On the western hill are the law courts, a fine block of buildings in classic style surmounted by a central dome. In Swanston Street there is a large building where under one roof are found the public library of over 100,000 volumes, the museum of sculpture, the art gallery, and the museum of edifices of art and technology. In connexion with the art gallery there is a travelling scholarship for art students, endowed by the state. The Exhibition Buildings are situated on a hill in Carlton Gardens; they consist of a large cruciform hall surmounted by a dome and flanked by two annexes. Here on the 4th of May 1901 the first federal parliament of the Australian commonwealth was opened by King George V. (as duke of Cornwall and York). The Trades Hall at Carlton is the meeting-place of the trades-union societies of Victoria, and is the focus of much political influence. The Melbourne town hall contains a central chamber capable of accommodating 3,000 people. Each of the cities and towns have each a town hall. The residence of the governor of the colony is in South Melbourne, and is surrounded by an extensive domain. The university is a picturesque mass of buildings in large grounds about a mile from the heart of the city. It comprises the university buildings proper, the medical school, the natural history museum, the Wilson Hall, a magnificent building in the Perpendicular style, and the three affiliated colleges, Trinity College (Anglican), Ormond College (Presbyterian) and Queen’s College (Wesleyan). The university, established in 1853, is under denominational, and grants degrees. The faculties of arts, law, medicine, civil engineering and music; instruction in theology is left to the affiliated colleges. Melbourne has numerous state schools, and ample provision is made for secondary education by the various denominations and by private enterprise. Of theatres, the Princess and the Theatre Royal are the most important. Other public buildings include the mint, the observatory, the Victoria markets, the Melbourne hospital, the general post office, the homoeopathic hospital, the custom house and the Alfred hospital. Many of the commercial buildings are of architectural merit, notably the banks, of which the bank of Australia, a massive edifice of the Doric order, and the Gothic Australian bank are the finest examples. The public gardens and parks of Melbourne are extensive. Within the city proper the Fitzroy Gardens are a network of avenues bordered with oak, elm and plane, with a “fern-tree gully” in the centre; they are ornamented with casts of famous statues, and ponds, fountains and classic temples. The Treasury, Flagstaff and Carlton Gardens are of the same class. Around the city lie five great parks—Royal Park, in which are excellent zoological gardens; Yarra Park, which contains the zoo, the Linnean Society, and the Botanic Garden; the Ladies of the banks of the river; Albert Park, in which is situated a lake much used for boating; and Studley Park on the Yarra river, a favourite resort which has been left in a natural state. Besides these parks, each suburb has its public gardens, and at Flemington there is a fine race-course, on which the Melbourne cup races are run every November, an event which brings in a large influx of visitors from all parts of Australia. Melbourne has a complete tramway system; all the chief suburbs are connected with the city by cable trams. The tramways are controlled by a trust, representing twelve of the metropolitan municipalities. The chief monuments and statues of the city are the statue of Queen Victoria in the vestibule of the Houses of Parliament, and a colossal group commemorating the explorers Robert O’Hara Burke (b. 1820) and William John Wills (b. 1834), who died of starvation in 1861 on an expedition for the crossing of Australia from south to north. There are also the statue to Sir Redmond Barry, first chancellor of the university, outside the public library, the Gordon statue in Spring Street, a replica of that in Trafalgar Square, London, and a statue of Daniel O’Connell, outside St Patrick’s cathedral.

Port Melbourne, originally called Sandridge, is about 2½ m. distant from the city, with which it is connected by rail and tramway. It has two large piers, alongside of which vessels of almost any tonnage can lie. One of these piers is served by the railway, and here most of the great liners are berthed. Ships drawing 22 ft. of water can ascend the river Yarra to the heart of the city. There are 2 m. of wharves along each bank of the river, with two large dry-docks and ship-repairing yards and foundries. Below Queen’s Bridge is an expansion of the river called the Pool, in which the largest ships using the river can turn with ease. Leading from a point opposite the docks is the Coode canal, by means of which the journey from the city to the mouth of the river is shortened by over a mile. As a port Melbourne takes the first place in Australia as regards tonnage. It is also a great manufacturing centre, and both city and suburbs have their distinctive industries. The chief are tanning, fellmongery, wool-washing, bacon-cutting, flour milling, brewing, iron-founding, brick-making, soap-boiling, the manufacture of pottery, candles, cheese, snuff, jams, biscuits, jewelry, furniture, boots, clothing and leather and woollen goods.

The climate of Melbourne is exceptionally fine; occasionally hot winds blow from the north for two or three days at a time, but the proportion of days when the sky is clear and the air dry and mild is large. Snow is unknown, and the average annual rainfall is 25.58 in. The mean annual temperature is 57.3°F., corresponding to that of Washington in the United States, and to Lisbon and Messina in Europe. The city is supplied with water from the Yan Yean works, an artificial lake at the foot of the Plenty Range, nearly 19 m. distant. The little settlement of the year 1835, out of which Melbourne grew, at first bore the native name of Dootigala, but it was presently renamed after Viscount Melbourne, premier of Great Britain at the time of its foundation. In June 1836 it consisted of only thirteen buildings, eight of which were turf huts. For two years after that date a constant stream of squatters with their sheep flowed in from around Sydney and Tasmania to settle in the Port Phillip district, and by 1841 the population of the town had grown to 11,000. The discovery of gold at Ballarat in 1851 brought another influx of population to the district, and the town grew from 30,000 to 100,000 in the course of two or three years. By 1854 Melbourne was incorporated and first sent members to the New South Wales parliament. A strong popular agitation caused the Port Phillip district to be separated from New South Wales in 1851, and a new colony was formed with the name of Victoria, Melbourne becoming its capital. In 1901 Melbourne became the temporary capital of the Australian commonwealth pending the selection of the permanent capital in New South Wales. The population of the city proper in 1901 was 653,474, and that of greater Melbourne was 496,079.

**MELBOURNE**, a market town in the southern parliamentary division of the Derbyshire, an electoral division of the Midland railway. Pop. (1901), 3580. It lies in an undulating district on a small southern tributary of the Trent, from which it is about 2 m. distant. The church of St Michael is a fine example of Norman work, with certain late details, having clerestoried nave, chancel and aisles, with central and two western towers. Melbourne Hall, a building of the time of William III., surrounded by formal Dutch gardens, stands in a domain owned at an early date by the bishops of Carlisle, whose tithe barn remains near the church. They obtained the manor of Linstock in 1333. In 1351 Robert de Holland fortified a mansion here, and in 1327 the castle belonged to Henry, earl of Lancaster; but it was dismantled in 1460, and little more than the site is now traceable. The title of Viscount Melbourne was taken from this town. There are manufactures of silk, and boots and shoes.
MELCHERS—MELEAGER

MELCHERS, (JULIUS) GARI (1860— ), American artist, was born at Detroit, Michigan, on the 11th of August 1860. The son of a sculptor, at seventeen he was sent to Düsseldorf to study art under von Gebhardt, and after three years went to Paris, where he worked at the Académie Julien and the École des Beaux Arts. Attracted by the pictorial side of Holland, he settled in Utrecht. His first important dated picture is "The Senora," brought him much favorable mention at the Paris Salon of 1886. He became a member of the National Academy of Design, New York; the Royal Academy of Berlin; Société Nationale des Beaux Arts, Paris; International Society of Painters, Sculptors and Engravers, London, and the Secession Society, Munich; and, besides receiving a number of medals, his decorations include the Legion of Honour, France; the order of the Red Eagle, Germany; and the Order of St Michael, Bavaria. Besides portraits, his chief works are: "The Supper at Emmaus," in the Krupp collection at Essen; "The Family," National Gallery, Berlin; "Mother and Child," Luxembourg; and the decoration, at the Congressional Library, Washington, "Peace and War." MELCHIADES, or MELITADES (other forms of the name being Meldiades, Meleidades, Mileiades and Militiades), pope from the 2nd of July 310, to the 11th January 314. He appears to have been an African by birth, but of his personal history nothing is known. The toleration edicts of Galerius and of Constantine and Licinius were published during his pontificate, which was also marked by the holding of the Lateran synod in Rome (313) at which Caezilius, bishop of Carthage, was acquitted of the charges brought against him and Donatus condemned. Melchiades was preceded and followed by Euschius and Silvester I. respectively.

MELCHITE (lit. Royalists, from Syriac melacha, a king), the name given in the 5th century to those Christians who adhered to the creed supported by the authority of the Byzantine emperor. The Melchites therefore are those who accept the doctrine of St. Irenæus known as Chalcedonianism, the Nestorians and Jacobite Church (q. q.). They follow the Orthodox Eastern liturgy, ceremonial and calendar, but acknowledge the papal and doctrinal authority of Rome. They number about 80,000, are found in Syria, Palestine and Egypt, and are under the immediate rule of the patriarch of Damascus and twelve bishops.

MELCHIZEDEK (Heb. for "king of righteousness"; or, since Šeqēk is probably the name of a god, "Šeqēk is my king"),king of S cere, is mentioned as "supreme El" (El 'ilyon), in the Bible. He brought forth bread and wine to Abraham on his return from the expedition against Chedorlomer, and addressed him in the name of the supreme God, possessor (or maker) of heaven and earth; and Abraham gave him tithes of all his booty (Gen. xiv. 18-20). Biblical tradition tells us nothing more about Melchizedek (cf. Heb. v. 3); but the majestic figure of the king-priest, prior to the priesthood of the law, to whom even the father of all Israel paid tithes (cf. Jacob at Bethel, Gen. xxvii. 22), suggested a figurative or typical application, first in Psalm cx. to the vicegerent of Yahweh, seated on the throne of Zion, the king of Israel who is also lord after the order of Melchizedek, and then, after the Gospel had ensured the Messianic interpretation of the Psalm (Matt. xxii. 42 seq.), to the kingly priesthood of Jesus, as that idea is worked out at length in the Epistle to the Hebrews.

The theological interest which attaches to the idea of the pre-Aaronic king-priest in these typical applications is practically independent of the historical questions raised by the various sources of Gen. xiv. The episode of Melchizedek, though connected with the main narrative by the epithets given to Yahweh in Gen. xiv. 22, breaks into a self-contained section of the book and at 1, and may perhaps have come originally from a separate source. As the narrative now stands Salem must be sought in the vicinity of "the king's dale," which from 2 Sam. xviii. 18, probably, but not necessarily, lay near Jerusalem. That Salem is Jerusalem, as in Psalm lxxxi. 2, it is the ancient and common view; but even in the 15th century B.C. Jerusalem was known as Urb-salim. Jerome and others have identified Salem with one or other of the various places which bear that name, e.g. the Σαλίμ of John iii. 23, 8 m. south of Bethshean. In a genuine record of extreme antiquity the union of king and priest in one man, the worship of a supreme deity in Canaanite, and the widespread practice of the consecration of a title of deity can present no difficulty; but, if the historical character of the narrative is denied, the date of the conception must be regarded as a specimen of the rise of the temporal authority of the high priests after the Exile. So far no evidence has been found in the cuneiform inscriptions or elsewhere in support either of the genuineness of the episode in its present form, or of the antiquity which is attributed to it (see T. E. Skinner, Genesis, pp. 269 sqq.). An ancient legend identifies Melchizedek with Shem (Palestinian Targum, Jerome on Isa. xli. 2, Ephraem Syrus in loco), or, from the literature on Gen. xiv., and other texts, Abrahams, GENESIS.

MELCOMB, GEORGE BUBB DODDINGTON, BARON (1661— 1762), English politician. His father's name was Bubb, but the son took the name of Doddington on inheriting a large property by the death of an uncle of that name (1720). He was educated at Oxford. In 1715 he was returned to parliament as member for Winchelsea, and was sent as envoy extraordinary to Spain. He carried on a scandalous traffic in the five or six parliamentary votes which he controlled, his turgidness and the carelessly furnishing of money for the political satirists and caricaturists of the day. His most esteemed and political action was his defence of Admiral Byng in the House of Commons (1757). From 1722 to 1754 he sat in parliament for Bridge-water; from 1724 to 1740 was a lord of the treasury; and, in 1744, became treasurer of the navy under Henry Pelham, and, again in 1755, under Newcastle and Fox. In April 1761 he was raised to the peerage as Baron Melcombe of Melcombe Regis in Dorsetshire. He died at La Trappe, his Hammersmith house, on the 28th of July 1762. His wife, acknowledged only after the death of another lady to whom he had given a bond that he would marry no one else, died without issue. He was a wit and a friend of wits, a good scholar, and something of a Maccaroni; Thomson's "Summer" was dedicated to him, Fielding addressed to him an epistle and Edward Young a satire. He was a leading spirit of the "Hell-fire Club, whose members, called "Franciscans," from their founder Sir Francis Dashwood (d. 1781), held their revels in the ruined Cistercian abbey of Medenham, Bucks.

His diary, published in 1784, reveals him in his character of politician and throws a curious light on the political methods of the time.

MELEAGER (Gk. Meleagros), in Greek legend, the son of Oeneus, king of Calydon, and Althaena. His father having neglected to sacrifice to Artemis, she sent a wild boar to ravage the land, which was eventually slain by Meleager. A war broke out between the Calydonians and Cretans (led by Althaena's brothers) about the disposal of the head and skin, which Meleager awarded as a prize to Atalanta, who had inflicted the first wound; the brothers of Althaena lay in wait for Atalanta and robbed her of the spoils, but were slain by Meleager. When Althaena heard this, she cursed Meleager, who witheld, and refused to fight until the Cretans were on the point of capturing the city of Calydon. Then, yielding to his wife's entreaties, he sallied forth and defeated the enemy, but was never seen again, having been carried off by the Erinyes, who had heard his mother's curse (or he was slain by Apollo in battle). According to a later tradition, not known to Homer, the Moerai appeared to Althaena when Meleager was seven days old, and announced that the child would only live as long as the log blazing on the hearth remained unaltered. Althaena thereupon seized the log, extinguished the flames, and bid it be fagots; places which her brothers' death, she relighted the log, and let it burn away until Meleager died.3 Then, horrified at what she had done, she hanged herself, or died of grief. The sisters of Meleager were

1 It is to be noted also that the name is of the same form as Adoni-zedek, king of Jerusalem (Josh. xix. 1) and the two Hebrew names of 2 Sam. xxiv. 16 is probably a corruption of the similar compound Adonijah (so Cheyne, Encyc. Bib. col. 290).

2 The god Ελι ου was also Phoenician; see Driver, Genesis, p. 105; Lagrange, Religions Sémitiques, Index, s.v. "Elyon," as representing the light of life, see E. Kuhnert in Rheinisches Museum, xlix., 1894, and J. Grimm, Teutonic Mythology (Eng. trans. by J. Stallybrass, 1880), ii. 853.
changed by Artemis out of compassion into guinea fowls and removed to the island of Leros, where they mourned part of the year for their brother. The life and adventures of Meleager were a favourite subject in ancient literature and art. Meleager is represented as a tall, vigorous youth with curly hair, holding a javelin in a boar’s head, and accompanied by a dog.

See R. Kekulé, De fabula meleagri dissertatio (1861); Surber, Die Melangerae (Zürich, 1880); articles on “Meleager” and “Meleagrides” in Roche’s Lexicon der Mythologie; L. Preller, Griechische Mythologie; Apollodorus i. 8; Homer, Iliad, ix. 577; Diod. Sicv. iv. 34; Dio Chrysostom, Or. 677; Hyginus, Fab. 171; Ovid, Metam. viii. 260–265. In the article GREEK ART (fig. 41) the hunting of the Calydonian boar is represented on a fragment of a frieze from a heroon.

**MELEDA** (Serbo-Croatian, Mijet; Lat. Melita), the third southern and easterly of the larger Adriatic islands of the Austrian province of Dalmatia. Pop. (1900), 1617. Meleda lies south of the Sabloncello promontory, from which it is divided by the Meleda Channel. Its length is 23 m.; its average breadth 2 m. It is of volcanic origin, with numerous chasms and gorges, of which the longest, the Bahinopole, connects the north and south of the island. For a Time, Meleda’s pastureable land on the north, is a port of call for tourist steamers. Meleda has been regarded as the Melita on which St Paul was shipwrecked, this view being first expounded, in the 10th century, by Constantine Porphyrogenitus. As at Malta, a “St Paul’s Bay” is still shown.

**MELEGNANO** (formerly Marignano), a town of Lombardy, Italy, in the province of Milan, 11 m. S.E. of that city by the railway to Piacenza, 280 ft. above sea-level. Pop. (1901), 6782. There are remains of a castle of the Visconti. Its military importance is due to its position at the crossing of the river Lambo. It was a stronghold of Milan in her great struggle against Lodi, and is famous for the victory of Francis I of France over the Swiss in 1515, known as the battle of Marignan, and for the action between the French and Austrians in 1859.

**MELEDANZUEÑO, JUAN** (1754–1817), Spanish poet, was born at Ribera del Fresno, Badajoz, on the 11th of March 1754. Destined by his parents for the priesthood, he graduated in law at Salamanca, where he became indoctrinated with the ideas of the French philosophical school. In 1780 with Batille, a pastor in the manner of Garcilaso de la Vega, he won a prize at the University of Salamanca. He was transferred two years later to a post in the chancery court at Valladolid. In 1797 he dedicated to Godoy an enlarged edition of his poems, the new matter consisting principally of unsuccessful imitations of Milton and Thomson; but the poet was rewarded by promotion to a high post in the treasury at Madrid. On the fall of Jovellanos in 1795 Meledanzeño was dismissed and exiled from the capital; he returned in 1808 and accepted office under Joseph Bonaparte. He had previously denounced the French usurer in his verses. He now outraged the feelings of his countrymen by the grossest flattery of his foreign master, and in 1813 he fled to Alcaraz. Four years later he died in poor fancy at Maupitière, his ashes were removed to Spain in 1900. In natural talent and in acquired accomplishment Meledanzeño was not surpassed by any contemporary Spaniard; he failed from want of character, and his profound insincerity affects his poems. Yet he has fine moments in various veins, and his imitation of Jean Second’s _Basía_ is notable.

**MELETIUS OF ANTIOCH** (d. 381), Catholic bishop and saint, was born at Melitene in Lesser Armenia of wealthy and noble parents. He first appears (c. 357) as a supporter of Acacius, bishop of Caesarea, the leader of that party in the episcopate which supported the _Homoian_ formula by which the emperor Constantius sought to effect a compromise between the Homoianians and the Homousians. Meletius thus makes his début as an ecclesiastic of the court party, and as such became bishop of Sebaste in succession to Eustathius, deposed as an Homousian heretic by the synod of Melitene. The appointment was by the Homousian clergy, and Meletius retired to Beroea. According to Socrates he attended the synod of Nicaea in the autumn of 359, and then subscribed the Acacian formula. He was also to become bishop of Antioch, in succession to Eudoxius, who had been raised to the see of Constantinople. Early in the following year he was in exile. According to an old tradition, supported by evidence drawn from Epiphanius and Chrysostom, this was due to a sermon preached before the emperor Constantius, in which he revealed Homousian views. This explanation, however, is rejected by Loofs; the sermon contains nothing inconsistent with the Acacian position favoured by the court party; on the other hand, there is evidence of conflicts with the clergy, quite apart from any polemics of orthodoxy, which may have led to the bishop’s deposition.

The successor of Meletius was Euzoeus, who had fallen with Arius under the ban of Athanasius; and Loofs explains the _sutura fidei mutatio_ (which St Jerome (ann. Abr. 2376) ascribes to Meletius to the dogmatic opposition of the deposed bishop to his successor. In Antioch itself Meletius continued to have adherents, who held separate services in the “Apostolic” church in the old town. The Meletian schism was complicated, moreover, by the presence in the city of another anti-Arian sect, stricter adherents of the Homousian formula, maintaining the tradition of the deposed bishop Eustathius and governed at this time by the presbyter Paulinus. The synod of Alexandria sent deputies to attempt an arrangement between the two anti-Arian Churches; but before they arrived Paulinus had been consecrated bishop by Lucifer of Calaris, and when Meletius—free to return in consequence of the emperor Julian’s contumacious policy—reached the city, he found himself one of three rival bishops. Meletius was now between two stools. The orthodox Nicene party, notably Athanasius himself, held communion with Paulinus only; twice, in 356 and 371 or 372, Meletius was exiled by decree of the Arian emperor Valens, a further complication was added when, in 375, Vitalius, one of Meletius’s presbyters, was consecrated bishop by the heretical bishop Apollinaris of Laodicea.

Meanwhile, under the influence of his situation, Meletius had been more and more approximating to the views of the newer school of Nicene orthodoxy. Basel of Caesarea, throwing over the cause of Eustathius, championed that of Meletius who, when after the death of Valens he returned in triumph to Antioch, was hailed as the leader of Eastern orthodoxy. As such he presided, in October 379, over the great synod of Antioch, in which the dogmatic agreement of East and West was established; it was he who helped Gregory of Nazianzus to the see of Constantinople and consecrated him; it was he who presided over the second ocumenical council at Constantinople in 381. He died soon after the opening of the council, and the emperor Theodosius, who had received him with especial distinction, caused his body to be carried to Antioch and buried with the honours of a saint. The Meletian schism, however, did not end with his death. In spite of the advice of Gregory of Nazianzus and of the Western Church, the recognition of Paulinus’s sole episcopate was refused, Flavian being consecrated as Meletius’s successor. The Eustathians, on the other hand, elected Evagrius as bishop on Paulinus’s death, and it was not till 415 that Flavian succeeded in re-uniting them to the Church.

Meletius was a holy man, whose ascetic life was all the more remarkable in view of his great private wealth. He was also a man of learning and culture, and widely esteemed for his honourable, kindly and straightforward character. He is venerated as a saint and confessor in both the Roman Catholic and Orthodox Eastern Churches.
The Romans identified Palaemon with Portunus (the harbour god). No satisfactory origin of the name Palaemon has been suggested. It has been suggested that it means the "wrestler" or "struggler" (παλαίμος) and is an epithet of Heracles, who is often identified with Melkar, but there does not appear to be any traditional connexion between Heracles and Palaemon.

The use of the name was being Phoenician, Palaemon also has been explained as the "burning lord" (Ba'al-hamman), but there seems little in common between a god of the sea and a god of the harvest.

In the 1890s, the town of Tetuan on the coast of Morocco, south of Cape Tres Forcas and 135 m. E.S.E. of Ceuta. Pop. about 9000. The town is built on a huge rock connected with the mainland by a rocky isthmus. There is a harbour, only accessible to small vessels; the roadstead outside is safe and has deep water a mile to the east of the town. From the landing-place, where a mole is cut out of the rock, there is a steep ascent to the upper town, characteristically Spanish in appearance. The town is walled, and the isthmus protected by a chain of small forts. A Moorish custom-house is placed on the Spanish border beyond the fort of Santa Isabel, and is the only authorized centre of trade on the Riff coast between Tetuan and the Algerian frontier. It thus forms the entrepôt for the commerce of the Riff district and its hinterland. Goat skins, eggs and beeswax are the principal exports, cotton goods, tea, sugar and candles being the chief imports. For the period 1901-1905 the annual value of the trade was about £20,000. Melilla, the first place captured by Spain on the African mainland, was seized from the Moors in 1490. The Spanishiers have had much trouble with the neighbouring tribes—turbulent Rifrians, hardly subject to the sultan of Morocco. The limits of the Spanish territory round the fortress were fixed by treaties with Morocco in 1859, 1860, 1861 and 1894. In 1893 the Rifians besieged Melilla and 25,000 men had to be despatched against them. In 1908 two companies, under the protection of El Rohgi, a chieftain then ruling the Rif region, started mining lead and iron some 15 m. from Melilla and a railway to the mines was begun. In October of that year the Rifians revolted from the Rohgi and raided the mines, which remained closed until June 1909. On the 9th of July the workmen were again attacked and several of them killed. Severe fighting between the Spanishiers and the tribesmen followed. The Rifians having submitted, the Spanishiers, in 1910, restarted the mines and undertook harbour works at Mar Chica.

See E. J. Hare, Herodotus, iii. 106-108, with the authorities there cited; and H. de Hennin, Histoire de la啡好.}

MELILA, a city and episcopal see of Basilicata, Italy, in the province of Potenza, 30 m. by rail N. of the town of that name. Meli is picturesquely situated on the lower slopes of Monte Vulture, 1591 ft. above sea-level. Pop. (1901), 14,547. The castle was originally erected by Robert Guiscard, but as it now stands it is mainly the work of the Doria family, who have possessed it since the time of Charles V.; and the noble cathedral which was founded in 1153 by Robert's son and successor, Roger, has had a modern restoration (though it retains its campaniles) in consequence of the earthquake of 1783. The church is considered one of the most beautiful in Italy, and one of the most crowded with the inhabitants perishing. It is the centre of an agricultural district which produces oil and wine. In the town hall is a fine Roman sarcophagus found 6 m. W. of Venosa.

Meli does not seem to occupy an ancient site, and its origin is uncertain. By the Normans it was made the capital of Apulia in 1031, and fortified. The council held by Nicholas I. in 1099, that of Urban II. in 1089, the rebellion against Roger in 1133 and the subsequent punishment, the plunder of the town by Barbarossa in 1137, the attack by Richard, count of Aquitaine, in 1190, and the parliament of 1223, in which Frederick II. established the constitution of the kingdom of Naples, form the principal points of interest in the annals of Meli. In 1346 Joanna I. of Naples bestowed the city of Meli to Arcello of Acquapendente, but in 1190 it was transferred to the Wolf.

MELICERTES, in Greek legend, the son of the Boeotian prince Athamas and Ino, daughter of Cadmus. Ino, pursued by her husband, who had been driven mad by the god Dionysus and had brought up the infant Dionysus, threw herself and Melicertes into the sea from a high rock between Megara and Corinth. Both were changed into marine deities—Ino as Leucothea, Melicertes as Palaemon. The body of the latter was carried by a dolphin to the Isthmus of Corinth and deposited under a pine tree. Here it was found by his uncle Sisyphus, who had it removed to Corinth, and by command of the Nereids instituted the Isthmian games and sacrifices in his honour. There seems little doubt that the cult of Melicertes was foreign, probably Phoenician, origin, and that it was introduced by Phoenician navigators on the coasts and islands of the Aegean and Mediterranean. He is a native of Boeotia, where Phoenician influences were strong; at Tenedos he was propitiated by the sacrifice of children, which seems to point to his identity with Melkart.

The premature death of the child in the Greek form of the legend is probably an allusion to this.
MELIORISM - MELITIC ACID

95
drama of the Alexandre Dumas type. One of his greatest successes was as Benvenuto Cellini, in which he displayed his ability both as an actor and as a sculptor, really modelling before the eyes of the audience a statue of Hebe. He sent a number of statuettes to the various exhibitions, notably one of Gilbert Louis Duprez as William Tell. Melingue’s wife, Théodoreние Thiesset (1813-1836), was the actress selected by Victor Hugo to create the part of Guanhumara in Burgavates at the Comédie Française, where she remained ten years.

See Dumas, Une Vie d’artiste (1854).

MELIORISM (Lat. melior, better), in philosophy, a term given to that view of the world which believes that at present the sum of good exceeds the sum of evil and that the same will continue, in the future, to continue to be the case.

It is said to have been invented by George Eliot to express a theory mediating between optimism and pessimism. The pragmatic movement in philosophy which puts stress upon the duty and value of effort is naturally favourable to the melioristic view: the best things that have been said recently in favour of it are found in books such as William James’s Pragmatism.

MELISSUS OF SAMOS, Greek philosopher of the Eleatic School (6th c.), was born probably not later than 470 B.C. According to Diogenes Laërtius, in xiv. 24, he was not only a thinker, but also a political leader in his native town, and was in command of the fleet which defeated the Athenians in 442. The same authority says he was a pupil of Parmenides and of Heraclitus, but the statement is improbable, owing to discrepancy in dates. His works, fragments of which are preserved by Simplicius and attested by the evidence of Aristotle, are devoted to the defence of Parmenides’s doctrine. They were written in Ionic and consist of long series of argument. Being, he says, is eternal. It cannot have had a beginning because it cannot have begun from not-being (cf. ex nihil nihil nihil), nor from being (et γὰρ ἀπὸ συνεχείας). It cannot suffer destruction; it is impossible for being to become not-being, and if it became another being, there would be no destruction. According to Simplicius (Physica, f. 22b), he differed here from Parmenides in distinguishing being and absolute being (τὸ δὲ αὐτὸ τὸ ἄθροο). He goes on to show that eternal being must also be unlimited in magnitude, and, therefore, one and unchangeable. Any change whether from internal or external source, he says, is unthinkable; the One is unvarying in quantity and in kind. There can be no division inside this unity, for any such division is again space or void; but void is nothing, and, therefore, is not. It follows further that being is incorporeal, inasmuch as all body has size and parts. The fundamental difficulty underlying this logic is the paradox more clearly expressed by Zeno and to a large extent represented in almost all modern discussion, namely that the evidence of the senses contradicts the intellect. Abstract argument has shown that change in the unity is impossible; yet the senses tell us that hot becomes cold, hard becomes soft, the living dies, and so on. From a comparison of Melissus with Zeno of Elea, it appears that the spirit of dialectic was already tentatively at work, though it was not conscious of its own power. Neither Melissus nor Zeno seems to have observed that the application of these destructive methods struck at the root not only of multiplicity but also of the One whose existence they maintained. The weapons which they forged in the interests of Parmenides were to be used with equal effect against themselves.

See Ritter and Preller, §§ 159-166; Brandis, Commentationum eleaticarum, pt. 1, p. 185; Mullach, Aristotelis de Melissio, Xenophane, Gorgio, Pseudo, De Melissi sancti fragmentis (Bonn, 1889), and histories of philosophy.

MELITO, bishop of Sardis, a Christian writer of the 2nd century, mentioned by Eusebius (Hist. Eccl. iv. 21) along with Hegesippus, Dionysius of Corinth, Apollinaris of Hierapolis, Irenaeus, and others, his contemporaries, as a champion of orthodoxy and upholder of apostolic tradition. Of his personal history nothing is known, and of his numerous works (which are enumerated—with quotations—by Eusebius) only a few fragments are extant. They included an Apologia addressed to Antoninus some time between A.D. 169 and 180, two books relating to the paschal controversy, and a work entitled Ἐθνογαί (selections from the Old Testament), which contained the first Christian list of “the books of the Old Covenant.” It excludes Esther, Nehemiah and the Apocrypha. The fragments have been edited with valuable notes by Routh (Reliquiae sacrae, vol. i, 1814). These are sufficient to show that Melito was an important figure in Asia Minor and took much part in the paschal, Marcionite and Montanist controversies.

It seems more than doubtful whether the Apologia of Melito “the Philosopher,” discovered in a Syrian translation by Henry Tattam (1780-1868), and subsequently edited by W. Curton and by Pitra-Renan, ought to be attributed to this writer and not to his pseudonym, as the Koïr (clavis), edited by Pitra-Renan, is a much later Latin collection of mystical explanations of Scripture.

See A. Harnack, Texte und Untersuchungen, i. 240-278 (Leipzig, 1882); Erwin Fraenkel, s.v. “Melito” in Herzog–Hauck, Real–encyclopaedie, xii., 1903, giving full list of works and bibliography.

MELKSHAM, a market town in the Westminster parliamentary division of Wiltshire, England, 93½ m. W. of London by the Great Western railway. Pop. of urban district (1901), 2450. It lies in a valley sheltered by steep chalk hills on the east, its old-fashioned stone houses lining a single broad street, which crosses the Upper Avon by a bridge of four arches. The church preserves some remnants of Norman work and a Perpendicular style, but much of rare beauty. Mells have been made here where coco-nut fibre and hair cloth are woven, flour-mills and dye-works. On the discovery of a saline spring in 1816, baths and a pump-room were opened, but although two other springs were found later, the attempt to create a fashionable health resort failed. The surrounding deer-forest was often visited by Edward I. Lacock Abbey, 3 m. distant, was founded in 1232 for Austin canonsesses, and dissolved in 1539. Portions of the monastic buildings remain as picturesque fragments in and near the mansion house called Lacock Abbey.

MELLE, a town of western France, capital of an arrondissement in the department of Deux-Sèvres, on the left bank of the Béronne, 21 m. E.S.E. of Niort by rail. Pop. (1906), 2531. Melle has two churches in the Romanesque style of Poitou, St Pierre and St Hilaire, the latter ornamented with sculptured arching. The hospital has a richly carved doorway of the 17th century. The church of St Savinien (11th century) serves as a prison. The town has trade in farm-produce, mules and other live stock; distilling is carried on. Melle (Melatinum) derives its name from the lead mine worked here during the Roman occupation and in the early middle ages. At the latter period it had a mint. In later times it was a possession of the comtes de Maine.

MELLITIC ACID (benzene hexacarboxylic acid), C₆(COOH)₆, was first discovered in 1799 by M. H. Klaproth in the mineral honeystone, which is the aluminium salt of the acid. The acid may be prepared by warming honeystone with ammonium carbonate, boiling off the excess of the ammonium salt and adding ammonium to the solution. The precipitated alumina is filtered off, the filtrate evaporated and the ammonium salt of the acid purified by recrystallization. The ammonium salt is then converted into the lead salt of the precipitate and the lead salt decomposed by sulphuric hydrogen.

The acid may also be prepared by the oxidation of pure carbon, or of hexamethyl benzene, in the cold, by alkaline potassium permanganate (F. Schulze, Ber., 1871, i, p. 802; C. Friedel and J. M. Crafts, Ann. chim. phys., 1884, i, p. 470). It crystallizes in fine silky needles and is soluble in water and alcohol. It is a very stable compound, chlorine, concentrated nitric acid and hydrochloric acid having no action upon it. It decomposes on dry distillation into carbon dioxide and pyromellitic acid, C₆H₄O₄; when distilled with lime it gives carbon dioxide and benzene. Long digestion of the acid with excess of phosphorus pentachloride results in the formation of the acid chloride, C₆(COCI), which crystallizes in yellow needles, melting at 190° C. By heating the ammonium salt of the acid to 150-160° C. as long as ammonia is evolved, a mixture of melanofuran and melanoacrylic acid is obtained. The mixture may be separated by dissolving out the ammonium eurchoate with water. Paraamide is a white amorphous powder, insoluble in water and alcohol.
MELLITUS (d. 624), bishop of London and archbishop of Canterbury, was sent to England by Pope Gregory the Great in 601. He was consecrated by St Augustine before 604, and a church was built for him in London by Aethelberht, king of Kent; this church was dedicated to St Paul, and MELLITUS became first bishop of London. About ten years later the East Saxons rebelled to paganism and the bishop fled from his see. He took refuge in Kent and then in Gaul but soon returned to England, and in 619 became archbishop of Canterbury in succession to Laurentius. He died on the 24th of April 624.

MELLONI, MACEDONIO (1798-1834), Italian physicist, was born at Parma on the 17th of April 1798. From 1824 to 1831 he was professor at Parma, but in the latter year he was compelled to escape to France, having taken part in the revolution. In 1839 he went to Naples and was soon appointed director of the Vesuvius observatory, a post which he held until 1848. Mellonii received the Rumford medal of the Royal Society in 1834. In 1835 he was elected correspondent of the Paris Academy, and in 1839 a foreign member of the Royal Society. He died at Portici near Naples of cholera on the 11th of August 1854. Mellonii's reputation as a physicist rests especially on his discoveries in radiant heat, made with the aid of the thermomultiplier or combination of thermopile and galvanometer, which, soon after the discovery of thermoelectricity by T. J. Seebeck, was employed by him jointly with L. Nobili in 1831. His experiments, which were used as the equivalent of the thermoelectricity in producing dark heat possessed by various substances and with the changes produced in the heat rays by passage through different materials. Substances which were comparatively transparent to heat he designated by the adjective “diathermane,” the property being “diathermanéité,” while for the heat-tint or heat-coloration produced by passage through different materials he coined the word “diathermansie.” In English, however, the terms were not well understood, and “diathermane” was generally used as the equivalent of the diathermanéité. In consequence Mellonii about 1841 began to use “diathermique” in place of “diathermane,” “diathermásie” in place of “diathermánie,” and “thermocrose” for “diathermansie.” His most important book, La thermocrose ou la coloration calorifique (vol. I., Naples, 1839), was unfinished at his death. He studied the reflection and polarization of radiant heat, the magnetism of rocks, electrostatic induction, daguerrotype, &c.

MELODRAMA (a coined word from Gr. μέλος, music, and ἀδρία, action), the name of several species of dramatic composition. As the word implies, “melodrama” is properly a dramatic mixture of music and action, and was first applied to a form of dramatic musical composition in which music accompanied the spoken words and the action, but in which there was no singing. The first example of such a work has generally been taken to be the Pygmalion of J. J. Rousseau, produced in 1775. This is the source of romantic dramas depending on sensational incident with exaggerated appeals to conventional sentiment rather than on play of character, and in which dramatis personæ follow conventional types—the villain, the hero wrongfully charged with crime, the persecuted heroine, the adventures, &c. At first the music was of some importance, forming practically a running accompaniment suitable to the situations—but this has gradually disappeared, and, if it remains, is used mainly to emphasize particularly strong situations, or to bring on or off the stage the various principal characters. Such plays first became popular in France at the beginning of the 19th century. One of the most prolific writers of melodramas at that period was R. C. G. de Fonvielle (1773-1844). The titles of some of his plays give a sufficient indication of their character; e.g. Victor, ou l'enfant de la forêt (1797); Carlina, ou l'enfant du mystére (1801); Le Monastère abandonné, ou la malédiction paternelle (1816). Another form of melodrama came from the same source, but developed on lines which laid more emphasis on the music, and is of some importance in the history of opera. Probably the first of this type is to be found in Georg Benda's Ariadne auf Naxos (1774). The most familiar of such melodramas is Gay's Beggar's Opera. In these the dialogue is entirely spoken. In true opera the spoken dialogue was replaced by recitative. It may be noticed that the speaking of some parts of the dialogue is not sufficient to class an opera as melodrama. This is as is proved by the dramatic and grave-digging scenes accompanied by the fine music in Fidélio, and the incantation scene in Der Freischiitz. To this the English term “declamation” is usually applied; the Germans use Melodram. But see Opera.

MELODY (Gr. μέλος, a choral song, from μείδω, tune, and σόνο, song). In musical philosophy and history the word “melody” must be used in a very abstract sense, as that aspect of music which is concerned only with the pitch of successive notes. Thus a “melodic scale” is a scale of a kind of music that is based on one particular system; and thus we call ancient Greek music “melodic.” The popular conception of melody is that of “air” or “tune,” and this is so far from being a primitive conception that there are few instances of such melody in recorded music before the 17th century; and even folk-songs, unless they are of recent origin, deviate markedly from the criteria of tunefulness. The modern conception of melody is based on the interaction of every musical category. For us a melody is the surface of a series of harmonies; and an unaccompanied melody so far implies harmony that if it so behaves as a simple harmonic expression clear key-relationships would be difficult to find for it is led by its form and content. Again, we do not feel music as melodious unless its rhythm is symmetrical; and this, taken together with the harmonic rationality of modern melody, brings about an equally intimate connexion between melody on a large scale and form on a small scale. In the article on SONATA FORMS it is shown that there are gradations between the form of some kinds of single melody like "Barbara Allen" (see Ex. 1) and the larger dance forms of the suite, and then, again, gradations between these and the other forms with their immense range of expression and development. Lastly, the most finely developed melody, the most strictly melodic, namely, the rise and fall of the pitch, is intimately connected by origin with the nature of the human voice, and in later forms is enlarged fully as much by the characteristics of instruments as by parallel developments in rhythm, harmony and form. Thus modern melody is the musical surface of rhythm, harmony, form and instrumentation; and, if we take Wagnerian Leitmotiv into account, we may as well add drama to the list. In short, melody is the surface of music.

We may here define a few technicalities which may be said to concern definitely the definition of melody than any other; but see also HARMONY and RHYTHM.

1. A theme is a melody, not necessarily or even usually complete, except when designed for a set of variations (q.v.), but of sufficient independence to stand by itself as a musical sentence. Thus a fugue-subject is a theme, and the first and second subjects in sonata form are more or less complex groups of themes.

2. A figure is the smallest fragment of a theme that can be recognized when transformed or detached from its surroundings. The grouping of figures into new melodies is the most obvious resource of "development" or "working-out" in the sonata-forms (see Ex. 2-7), besides being the main resource by which fugues are carried on at those moments in which the subjects and counter-subjects are not present as wholes. In 16th-century polyphony which consists mainly of figures thus broken off from a cantus firmo (see CONTRAPUNTAL FORMS).

3. Polyphony is simultaneous multiple melody. In 16th-century music all fugue-writing every part is as melodious as the other. The popular cry for melody as an antidote to polyphony is thus really a curious perversion of the complaint that one may have too much of a good thing. Several well-known classical melodies are polyphonic in essence, being formed by an inner melody appearing as it were through transparent places in the outer melody, which it thus completes. This is especially common for the pianoforte, where the tone of long notes rapidly fades away, and the works of Chopin are full of examples. In Bach's works for keyed instruments figures frequently have a double meaning on this principle, as, for instance, in the peculiar kind of counterpoint in the 15th fugue of the 2nd book of the Welltempered Klavier. A good example of a simple melody which, as written by the composer, would need two voices to sing it, is that
which begins the second subject of Beethoven's *Waldstein Sonata* (Op. 53, first movement, bars 35-42, where at the third bar of the melody a lower voice enters and finishes the phrase).

4 (a) **Conjunct movement** is the movement of melody along adjacent degrees of the scale. A large proportion of Beethoven's melodies are conjunct (see Ex. 2, fig. B).

4 (b) **Disjunct movement**, the opposite of conjunct, tends, though by no means always, to produce arpeggio types of melody, i.e. melodies which move up and down the notes of a chord. Certain types of such melody are highly characteristic of Brahms; and Wagner, whose melodies are almost always of instrumental origin, is generally disjunct in diatonic melody and conjunct in chromatic (Ex. 2, fig. C, is a disjunct figure not forming an arpeggio).

For various other melodic devices, such as inversion, augmentation and diminution, see CONTRAPUNTAL FORMS.

We subjoin some musical illustrations showing the treatment of figures in melody as a means of symmetry (Ex. 1), and development (Ex. 2-7), and (Ex. 8-13) some modern melodic transformations, differing from earlier methods in being immediate instead of gradual.

The melon is a species of the genus *Cucumis*, a polymorphic species of the order Cucurbitaceae, including numerous varieties. The melon is an annual trailing herb with palmately-lobed leaves, and bears tendrils by means of which it is readily trained over trellises, &c. It is monoeocious, having male and female flowers on the same plant; the flowers have deeply five-lobed campanulate corollas and three stamens. Naudin observed that in some varieties (e.g. of Cantaloupes) fertile stamens sometimes occur in the female flowers. It is a native of southern Asia from the foot of the Himalayas to Cape Comorin, where it grows spontaneously, but is cultivated in the temperate and warm regions of the whole world. It is variable both in diversity of foliage and habit, but much more so in the fruit, which in some varieties is no larger than an olive, while in others it rivals the gourd (*Cucurbita maxima*). The fruit is ovoid, ovate, spindle-shaped, ribbed, or furrowed, variously coloured externally, with white, green, or orange flesh when ripe, scented or scentless, sweet or insipid, bitter or even nauseous, &c. Like the gourd, the melons undergoes strange metamorphoses by crossing its varieties, though the latter preserve their characters when alone. The offspring of all crossings are fertile. As remarkable cases of sudden changes produced by artificially crossing races, M. Naudin reports that in 1859 the offspring of the wild melons *m. savage de l'Inde* (*C. melo argenteus*) and *m. s. d'Afrique*, the *petit m. de Figari* bore different fruits from their parents, the former bearing about twelve times their size, ovoid, white-skinned, or more or less scented, and with reddish flesh; though another individual bore fruits no larger than a nut. The offspring of *m. de Figari* after being crossed bore fruits of the serpent-melon. On the other hand, the serpent-melon was made to bear ovoid and reticulated fruit.

Naudin thinks it is probable that the culture of the melon in Asia is as ancient as that of all other alimentary vegetables. The Egyptians grew it, or at least inferior races of melon, which were either indigenous or introduced from Asia. The Romans and the Greeks were familiar with it, though some forms which they may have been described as cucumbers. Columella seems to refer to the serpent-melon in the phrase *ut colubro...centrum cubat flexo*. Pliny describes them as *pepones* (ix. 23 to xx. 6) and Columella as *melones* (xi. 2, 53). The melon began to be extensively cultivated in France in 1629, according to Olivier de Serres. Gerard (*Herball, 1772*) figured and described in 1597 several kinds of melons or pompons, but he has included gourds under the same name.

The origin of the chief modern races, such as *Cantaloupes*, *Dudaim,* and probably the netted sorts, is due to Persia and the neighbouring Caucasian regions. The first of these was brought to Rome from Armenia in the 16th century, and supplies the chief sorts grown for the French markets; but many others are doubtless artificial productions of west Europe.

The water-melon (*Citrullus vulgaris*) is a member of a different genus of the same order. It has been cultivated for its cool refreshing fruit since the earliest times in Egypt and the Orient, and was known before the Christian era in southern Europe and Asia.

The melon requires artificial heat to grow it to perfection, the rock and cantaloup varieties succeeding with a bottom heat of 70° and an atmospheric temperature of 75°, rising to 80° at the top. The melon and the Persimmon require a bottom heat of 75°, gradually increasing to 80°, and an atmospheric temperature ranging from 75° to 80° when the fruit is swelling, as much sun heat as the plants can stand, watered down at all times. The melon is grown in rich loamy loam, somewhat heavy, with which a little well-rotted dung, especially that of pigeons or fowls, should be used, in the proportion of one-part mixed in the compost of loam. The melons are grown on beds of frames covered with glass. The fruit should be about a foot in thickness, or in pots heated either by hot water or fermenting matter, or in houses heated by hot water, in which case the soil bed should be 15 or 18 in. thick. The heating materials should be well prepared, and, since the heat has to be kept up by linings, it is a good plan to introduce one or two layers of faggots in building up the bed. A mixture of dung and leaves makes a more subtle heat than that of wood.

For all ordinary purposes February is early enough for sowing the first crop, as well-flavoured fruits can scarcely be looked for before May. The seeds may be sown singly in 3-in. pots in a mixture of leaf-mold with a little loam, the pots being plunged in a bottom heat of 75° to 80°, and as near the glass as possible, in order that the young plants may not be drawn up. The full or ridge of soil should be about a foot thickness, the rest of the surface being covered made up nearly to the same level. If the fruit-bed is not ready when the roots have nearly filled the pots, they must be shifted into 4-inch pots, for they must not get starved or pot-bound. Two or three pots and there shaped to the size of an egg, it should be placed in the centre of each light, and the rest of the surface is covered over to a similar depth as soon as the roots have made their way through the mound.

The serpent-melon being a melon which grows on plants which produce distinct male and female flowers, it is necessary to its fertility that both should be produced, and that the pollen of the male flower should be transferred to the female. This may be done by natural manipulation, or by being conveyed to the stigma of the female flower; this setting of the fruit is often done by stripping a male flower of its corolla, and inverting it in the centre of the fruit-bearing flower. After the fruit has set and has grown to the size of an egg, it should be preserved from contact with the soil by placing it on a piece of tile or slate; or if grown on a trellis by a little swinging wooden shelf, just large enough to hold it. In either case the material used should be tilted a little to one side, so as to permit water to drain away. Before the process of ripening commences, the roots should have a sufficient supply of moisture, so that none may be required from that time until the fruit is cut.

When the melon is grown in a house there should be a good depth of drainage over the tank or other source of bottom heat, and on this should be placed turf, grass side downwards, below the soil, which should not be less than 15 and need not be more than 18 in. in thickness. The compost should be made moderately firm, and only half the bed should be made up at first, the rest being added as the roots require. The melon may also be grown in hotbeds, supplied with artificial manure or manure water. The stems may be trained up the trellis in the usual way, or the rafter of a pine stove may be utilized for the purpose. If the trellis is not used, the melons may be grown in boxes, one in one, or two in pairs, and the boxes may be taken down and conveniently stowed away when not in use.

The presence of too much moisture either in the atmosphere or in the soil is apt to cause the plants to slump off at the neck, but this can be checked by applying a little fresh-slaked lime round the stem of the plant.

Melons are liable to the attack of red spider, which are best removed by spraying with rain-water, and prevented by keeping a fairly humid atmosphere; green or black fly should also be watched for and removed by fumigation with tobacco smoke or by "vaporizing." The varieties of melon are continually receiving additions, and as newer varieties spring into favour, so the older ones drop out of cultivation. A great deal depends on getting the varieties true to name, as they are very liable to get cross-fertilized by insect agency. Some of the modern varieties are:

- Scarlet-fleshed.—Blenheim Orange, Frogmore Orange, Invincible, Sutton's Scarlet, and Triumph.
- White-fleshed.—Golden Orange, Hero of Longleat, Longleat Perfection, Royal Favourite.
- Green-fleshed.—British Queen, Epicure, Exquisite, Monarch, Ringleader.
- Hybrid.—Hermine de Montreuil-gardeners round Paris and other parts of France chiefly cultivate varieties of Cantaloup melon known as the Prescott blatté à chasselas and Prescott fond blanc—both excellent in flavour. They are apt to be rather coarse, and do not thrive in hot water, but large fruit is allowed to mature on each plant. If secured early in the season—say in June—from 25 to 35 francs can be obtained for each fruit in the Paris markets; later fruits, however, drop down to 2 francs each, or even lower when there is a glut (see J. Weathers, *French Market-Gardening*).

**MELORIA**, a rocky islet, surrounded by a shoal, almost opposite Leithorn. It was the scene of two naval battles of the
middle ages. The first, on the 3rd of May 1241, was fought between the fleet of the emperor Frederick II. Hohenstaufen, surnamed Stupor Mundi, in alliance with Pisa, against a Genoese squadron bringing a number of English, French and Spanish prelates to attend the council summoned to meet at the Lateran by Gregory IX. Three Genoese galleys were sunk and twenty-two taken. Several of the prelates perished, and many were carried prisoners to the camp of the emperor. The second, fought on Sunday the 6th of August 1284, was of higher historical importance. It was a typical medieval sea-fight, and accomplished the ruin of the Genoese power. The long line of the Genoese fleet had broken up for the last time in 1282, the immediate cause being the incompatible claims of the two cities to sovereignty over the islands of Sardinia and Corsica. The earlier conflicts of the war in 1282, 1283 and the spring of 1284, had been unfavourable to Pisa. Though the city was united with the Catalans and with Venice in hostility to Genoa, and though it had chosen a Venetian, Alberto Morosini, as its Podestà, it received no help from either. The Genoese, who had the larger and more efficient fleet, sent their whole power against their enemy. When the Genoese appeared off Meloria the Pisan fleet, lying off Gattilusa, retreated from the port of the Amalfici, and Andrea de' Porto Pisano the port of the city. The Pisan fleet represented the whole power of the city, and carried members of every family of mark and most of the great officers of state. The Genoese, desiring to draw their enemy out to battle, and to make the action decisive, arranged their fleet in two lines abreast. The first was composed according to Agostino Giustiniani of fifty-eight galleys, and eight panfilii, a class of light galleys of eastern origin named after the province of Pamphylia. Uberto Doria, the Genoese admiral, was stationed in the centre and in advance of his line. To the right were the galleys of the Spinola family and of four of the eight "companies" into which Geno's was divided—Castello, Piazzalonga, Magagnana and Son Lorenzo. To the left were the galleys of the Doria's, and of the other four Doria's, Porta, Soziglia, Porta Nuova and Il Borgo. The second line of twenty galleys, under the command of Benedicto Giacaria (or Zacchatter), was placed so far behind the first that the Pisans could not see whether it was made up of war-vessels or of small craft meant to act as tenders to the others. Yet it was near enough to strike in and decide the battle when the action had begun. The Pisans, commanded by the Podestà Morosini and Andrea della Bella, of the family of the Saraceno, came out in a single body. It is said that while the archbishop was blessing the fleet the silver cross of his archepiscopal staff fell off, but that the omen was disregarded by the irreverence of the Pisans, who declared that if they had the wind they could do without divine help. They advanced in line abreast to meet the first line of the Genoese, fighting according to the medieval custom to ram and board. The victory was decided for Genoa by the squadron of Giacaria which fell on the flank of the Pisans. Their fleet was nearly annihilated, the Podestà was taken, and Ugolino of the Spinola family, as Pisa was also attacked by Florence and Lucca it could never recover the disaster. Two years later Genoa took Porto Pisan, and filled up the harbour. The count Ugolino was afterwards starved to death with several of his sons and grandsons in the manner made familiar by the 32nd canto of Dante's Inferno.

MELOS (mod. Milo), an island of the Aegean Sea (Cyclades group), at the S.W. corner of the archipelago, 75 m. due E. from the coast of Laconia. From E. to W. it measures about 14 m., from N. to S. 8 m., and its area is estimated at 52 sq. m. The greater portion is rugged and hilly, culminating in Mount Elias in the west (2538 ft.). Like the rest of the cluster, the island is of volcanic origin, with tuff, trachyte and obsidian among its ordinary rocks. The natural harbour, which, with a depth diminishing from 70 to 30 fathoms, strikes in from the north-west so as to cut the island into two fairly equal portions, with an isthmus not more than 1½ m. broad, is the hollow of the principal crater. In one of the caves on the south coast the heat is still great, and on the eastern shore of the harbour there are hot sulphurous springs. Sulphur is found in abundance on the top of Mount Kalamo and elsewhere. In ancient times the alum of Melos was reckoned next to that of Egypt (Pliny xxxv. 15 [52]), and millstones, salt (from a marsh at the east end of the harbour), and gypsium are still exported. The Melian earth (γύ Μηλία) was employed as a pigment by ancient artists. Orange, olive, cypress and arbutus trees grow throughout the island, which, however, is too dry to have any profusion of vegetation. The vine, the cotton plant and barley are the main objects of cultivation. Pop. (1907), 4864 (commune), 13,774 (province).

The ancient town of Melos was about 2½ m. N.W. of the present town, and was known as Amilara, and from this there is an ascent to the plateau above the harbour, on which are situated Plaka, the chief town, and Kastro, rising on a hill above it, and other villages. The ancient town of Melos was nearer to the entrance of the harbour than Amanta, and occupied the slope between the village of Trypete and the landing-place at Klima. Here is a theatre of Roman date and some remains of town walls and other buildings, one with a fine mosaic excavated by the British school at Athens in 1896. Numerous fine works of art have been found on this site, notably the Aphrodite of Melos in the Louvre, the Empress of Egypt, and the British Apollo, and the archaic Apollo in Athens. The position of Melos, between Greece and Crete, and its possession of obsidian, made it an important centre of early Aegean civilization. At this time the chief settlement was at the place now called Phylakopi, on the north-east coast. Here the excavations of the British school cleared many houses, including a palace of "Mycenaean" type; there is also a town wall. Part of the site has been washed away by the sea. The antiquities found were of three main periods, all preceding the Mycenaean age of Greece. Much pottery was found, including fine examples of a peculiar style, with decorative designs, mostly floral, and also considerable deposits of obsidian. There are some traditions of a Phoenician occupation of Melos. In historical times the island was occupied by Darians from Laconia. In the 6th century it again produced a remarkable series of vases, of large size, with mythological subjects and orientalizing ornamentation (see GREEK ART, fig. 9), and also a series of terra-cotta reliefs.

Though Melos inhabitants sent a contingent to the Greek fleet at Salamis, it held aloof from the Attic league, and sought to remain neutral during the Peloponnesian War. But in 416 B.C. the Athenians, having attacked the island and compelled the Melians to surrender, slew all the men capable of bearing arms, made slaves of the women and children, and introduced 300 Athenian colonists. Lysander restored the island to its Dorian possessors, but it never recovered its former prosperity. There were many Jewish settlers in Melos in the beginning of the Christian era, and Christianity was early introduced. During the "Frankish" period the island formed part of the duchy of Naxos, except for the few years (1341-1383) when it was a separate lordship under Marco Sanudo and his daughter.

Antimilos or Antimilia, 2½ m. north-west of Milo, is an uninhabited mass of trachyte, often called Eremomilo or Desert Melos. Kimos or Argentea, less than 1 m. to the north-east, was famous in antiquity for its figs and fuller's earth (Κωμοσ γ') and contained a considerable city, the remains of which cover the cliff of St Andrews. Polinos, Polybios or Polivo (anc. Polygeos) lies rather more than a mile south-east of Kimos. It was the subject of dispute between the Melians and Kimolians. It has long been almost uninhabited.

MEZZO DA FORLÌ (c. 1438-1494), Italian painter, the first who practised foreshortening with much success, was born at Forlì about 1438; he came, it is supposed, of a wealthy family named Ambrosi. In all probability, Mezzo studied painting under Piero de' Franceschi, of Borgo St Sepolcro; he seems also to have been well acquainted with Giovanni Santi, the father of
Raphael. It has been said that he became a journeyman and colour-grinder to some of the best masters, in order to prosecute his studies; this lacks confirmation. Only three works are extant which can safely be assigned to Melozzo: those in the Louvre, the National Gallery, London, and the Barberini Palace, Rome, are disputable. (1) He painted in 1472 the vault of the chief chapel in the church of the Apostoli in Rome, his subject being the "Ascension of Christ"; the figure of Christ is so boldly and effectively foreshortened that it seems to "burst through the vaulting"; this fresco was taken down in 1711, and the figure of Christ is now in the Quirinal Palace, not worthy of special admiration save in its perspective quality; while in the other portions, almost Raphaelæusque in merit, are the sacristy of St Peter's. (2) Between 1475 and 1480 he executed a fresco, now transferred to canvas, and placed in the Vatican picture-gallery, representing the appointment of Platina by Pope Sixtus IV. as librarian of the restored Vatican library. (3) In the Collegio at Forli is a fresco by Melozzo, termed the "Pestapepe," or Pepper-grinder, originally painted as a grocer's sign; it is an energetic specimen of rather coarse realism, now much damaged. Melozzo also painted the cupola of the Capucine church in Rome; this was destroyed and it has been executed at Urbino some of the portraits of great men (Plato, Dante, Sixtus IV., &c.) which are now divided between the Barberini Palace and the Campana collection in Paris; this, however, is doubtful, and it is even questionable whether Melozzo was ever at Urbino. In Rome he was one of the original members of the academy of St Luke, founded by Sixtus IV. He returned to Forli, probably towards 1480, and died in November 1494. He contributed sensibly to the progress of pictorial art; and, without being remarkable as a colourist, gave well graded lights, with general care and finish, and fine dignified figures. His works bear a certain resemblance to those of his contemporary Mantegna. Marco Palmezzano was his pupil; and the signature "Marcus de Melotius" on some of Palmezzano's works, along with the general affinity of style, has led to their being ascribed to Melozzo, who has hence been incorrectly called "Marco Melozzo."

MELROSE, a city of Middlesex county, Massachusetts, U.S.A., about 7 m. N. of Boston. Pop. (1890), 8519; (1900), 12,992, of whom 2924 were foreign-born and 139 were negroes; (1910 census) 15,715. It is served by the Boston & Maine railroad, and by inter-urban electric railways. The city covers 4-8 sq. m. of broken, hilly country, in which is a part of the state park of Middlesex Fells; it includes the villages of Melrose, Melrose Highlands, Wyoming and Fells. In 1905 the total factory product was valued at $6,450,920 (an increase of 176-6% over the value of the factory product in 1900). The principal products are rubber shoes (at the village of Fells), skirts (at the village of Wyoming), and leather and silverware (at Melrose Highlands). The water supply of Melrose, like that of Stoneham and of Medford, is derived from the metropolitan reservoir called Spot Pond in Stoneham, immediately west of Melrose. The city was the home of Samuel Adams Drake (1833-1905), American historian, whose History of Middlesex County (Boston, 1880; vol. 2, "Melrose," by E. H. Goss) should be consulted; and of William Frederick Poole (1821-1894), the librarian and the originator of indexes of periodical literature. Melrose was settled about 1633, and was a part of Charlestown until 1649, and of Malden until 1830. The eastern part of Stoneham was annexed to it in 1853. In 1899 it was chartered as a city; the charter came into effect in 1900. The name is said to be due to a resemblance of the scenery to that of Melrose, Scotland.

MELROSE, a police burgh of Roxburghshire, Scotland. Pop. (1901), 2105. It lies on the right bank of the Tweed, 374 m. S.E. of Edinburgh, and 19 m. N.W. of Jedburgh, via St Boswells and Roxburgh, by the North British railway. The name—which Bede (730) wrote Mailros and Simeon of Durham (1130) Melros—is derived from the Celtic mail ros, "bare moor," and is supposed to have been given by Sir Walter Scott's Abbots and Monastery as "Kennaquhair." In consequence of the beauty of its situation between the Eildons and the Tweed, the literary and historical associations of the district, and the famous ruin of Melrose Abbey, the town has become a residential and a holiday resort. There is a hydropathic establishment on Skirrghill, the name commemorating the fact that on the 25th of July 1356, in which the Scots defeated the Douglases and Kers. Trade is almost wholly agricultural. The main streets run from the angles of the triangular market-place, in which stands the market cross, dated 1642, but probably much older. Across the river are Gattonside, with numerous orchards, and Allerley, the home of Sir David Brewster from 1827 till his death in 1868. Melrose Abbey, the original Columban monastery was founded in the 7th century at Old Melrose, about 2½ m. to the east, in the loop of a great bend of the Tweed. It was colonized from Lindisfarne, Eata, a disciple of Aidan, being the first abbot (611), and Boisil and Cuthbert being priors here. It was burned by Kenneth Macalpine in 839 during the wars between Scot and Saxon, and, though rebuilt, was deserted in the middle of the 11th century. The chapel, dedicated to St Cuthbert, continued for a period to attract many pilgrims, but this usage gradually declined and the building was finally destroyed by English invaders. Meanwhile in 1137, William III. appointed an abbot, dedicated to the Virgin, a little higher up the Tweed, the first Cistercian settlement in Scotland, with monks from Rievaulx in Yorkshire. Lying in the direct road from England, the abbey was frequently assaulted and in 1322 was destroyed by Edward II. Rebuilt, largely by means of a gift of Robert Bruce, it was nearly burned down in 1385 by Richard II. Erected once more, it was reduced to ruin by the earl of Hertford (afterwards the Protector Somerset) in 1545. Later the Reformers dismantled much of what was left. The adaptation of part of the nave to the purposes of a parish church and the use of the building as a quarry did further damage. The ruins, however, now the property of the duke of Buccleuch, are carefully preserved. Of the conventual buildings apart from the church nothing has survived but a fragment of the cloister with a richly-carved round-headed doorway and some fine arcading. The abbey, cruciform, is in the Decorated and Perpendicular styles, with pronounced French influence, due probably to the master mason John Morow, or Morroe, who, according to an inscription on the south transept wall, was born in Paris. The south front is still beautiful. The west front and a large portion of the north half of the nave and aisle have perished, but the remains include the rest of the nave, the two transepts, the chancel and choir, the two western piers of the tower and the sculptured roof of the east end. From east to west it measured 258 ft., the nave is 69 ft. wide and the width of the transepts from north to south is 115 ft. The nave had an aisle on each side, the north noticeably the narrower, the south furnished with eight chapels, one in each bay. Both transepts contained an eastern aisle, and the chancel a square chapel at its west end on each side. Over the south transept aisle, which was the chapel of St Bridget, is the clerestory passage, which ran all round the church. The choir extended westward for three bays beyond the tower and terminated in a stone rood-screen. Sir Walter Scott has immortalized the east window, in The Lay of the Last Minstrel, but the south window with its flowing tracery is even finer. In the carving of windows, aisles, cloister, capitals, bosses and doorheads no design is repeated. The heart of Robert Bruce was buried at the high altar, and in the chancel are the tombs of Sir William Douglas, the Knight of Liddesdale (1300-1335), James 2nd earl of Douglas (1330-1388), the victor of Otterburn; Alexander II.; and Michael Scott, the "Wizard" (1173-1234)—though the authors may say that this is the tomb of Sir Brian Layton, who fell in the battle of Acrum Moor (1544). At the door leading from the north transept to the sacristy is the grave of Joanna (d. 1238), queen of Alexander II.

The manuscripts of the abbey, preserved in the archives of the earl of Morton, were edited by Cosmo Innes for the Bannatyne Club and published in 1837 under the title of Liber sancte Mariae Magdalenæ in Mino Melrose. Among the documents is one of the earliest specimens of the Scots dialect. The Chronicle of De Maledictis, written among the Cotton MSS., was printed at Oxford in 1684 by William Fulman and by the Bannatyne Club in 1835 under the editorship of John Stevenson.
MELTON MOWBRAY, a market town in the Melton parliamentary division of Leicestershire, England, pleasantly situated in a fertile vale, at the confluence of the Wreake and the Eye. Pop. of urban district (1901), 7454. It is 105 m. N.N.W. from London by the Midland railway, and is served by a joint branch of the London & North Western and Great Northern railways. The church of St Mary, a fine cruciform structure, Early English and later, with a lofty and richly ornamented central tower, was enlarged in the reign of Elizabeth. Melton is the centre of a celebrated hunting district, in connexion with which there are large parks and deer parks. The nobly-born Melton is known for its pork pies, and has a trade in Stilton cheese. There are brevarey and tanneries and an important cattle market. There are blast furnaces in the neighbouring parish of Askdalford for the smelting of the abundant supply of iron ore in the district. During the Civil War Melton was in February 1644 the scene of a defeat of the parliametary forces by the royalists. It is the birthplace of John Henley the orator (1602-1759).

MELUN, a town of northern France, capital of the department of Seine-et-Marne, situated north of the forest of Fontainebleau, 28 m. S.S.E. of Paris by rail. Melun (1006), i1,710. The town is built on the site of an oppidum occupied by the Sequani and a portion lies on the slope of a hill on the right bank; on the left bank is the most modern quarter, while the old Roman town occupies an island in the river. On the island stands the Romanesque church of Notre-Dame (11th and 12th centuries), formerly part of a nunnery, the site of which is occupied by a prison. The other public buildings are on the right bank of the river. Of these, the most striking is the church of St Aspais, an irregularly shaped structure of the 13th and 16th centuries, on the apse of which may be seen a modern medallion in bronze, the work of the sculptor H. Chapu, representing Joan of Arc as the liberator of Melun. The hôtel-de-ville (1874)—in the construction of which an old mansion and turret have been utilized—and the tower of St Bartholomew of the 16th and 18th centuries are also of interest. In the courtyard of the former there is a monument to Jacques Amyot, the translator of Plutarch, who was born at Melun in 1513. Among the rich estates in the neighbourhood the most remarkable is the magnificent château of Vaux-le-Vicomte, which belonged to Nicholas Fouquet, intendant of finances under Louis XIV. Melun is a market for grain and farm produce, and has industries, including brewing, tanning, distilling, the manufacture of clothes for garments, lime cement, and plaster.

Caesar's Gallic wars Melun (Melodunum) was taken by his lieutenant Labienus, in order to facilitate the attack of Lutetia by the right bank of the Seine. It was pillaged by the Normans, and was the residence of the first kings of the race of Capet; Robert and Philip I. both died here. In 1359 Melun was given up by Jeanne de Navarre to her brother, Charles the Bad, but was retaken by the dauphin Charles and Bertrand Dagueselin. In 1420 it was the scene of a bloody fight against Henry V. of England and his ally the duke of Burgundy. Ten years later the people of Melun, with the help of Joan of Arc, drove out the English. It was occupied by the League in 1589, and retaken by Henry IV. in the following year.

MÉLUSINE, the tutelary fairy of the house of Lusignan, was the eldest daughter of the fairy Pressine, to avenge whose wrongs she shut up her father in a mountain in Northumberland. For this she was condemned to be metamorphosed every Saturday into a woman-serpent—that is, to be a serpent from the hips downwards. She might, however, be eventually saved from this punishment if she could find a husband who would never see her on a Saturday. Such a husband was found in Raymond, nurse of the count of Poitiers, who became rich and powerful through the machinations of his wife. She built the castle of Lusignan and many other of the family castles. When her husband gave way to his curiosity, and saw her taking the bath of purification on a Saturday she flew from the castle in the form of a serpent. Thenceforward the death of a member of the house of Lusignan was heralded by the cries of the fairy serpent. "Pousser des cris de Mélusine" is still a popular saying.

This history is related at length, with the adventures of Mélusine's numerous progeny, by Jean d'Arras, in his Chronique de la princesse, written in 1387 at the desire of John, duke of Berry, for the amusement of the duke and of his sister Marie of France, duchess of Milan. It is one of the most charming of the old prose romances in manner and style, and is natural in spite of the free use of the marvellous. An attempt has been made by Jules Baudot in Les Princesses Yolande et les ducs de Bar (Paris, 1900) to make it a roman à clef and to identify the personages. Mélusine, Melusine or Merlusine is, however, simply the spirit of the fountain of Lusignan, and the local Poitevin myth is attached to the symbol of the snake. Mélusine has been variously and fancifully given. Some writers have supposed Mélusine to be a corruption of mère Lucine (moter Lucina), the deity invoked in child-birth. She has been identified with Mélesinde, widow of a king of Jerusalem, and with Mervide, wife of Geoffrey of Lusignan.

The Mélusine of Jean d'Arras was printed by Adam Stinschaber at Geneva in 1478, and was reprinted many times in the 15th and 16th centuries. It has been translated into Spanish, English, German and Flemish. Modern editions are by J. C. Brunet (Paris, 1854), and by E. Lecesne for the Academy of Arras (Arras, 1888). The Mélusine of the Modern edition is extracted from a unique MS. in the British Museum by A. K. Donald for the E.-T.S. (1865). The tale was versified in the 14th century by a poet called Coulodrette, whose poem was published in 1854 by Francisque Michel. See also R. Dunlop, ed., of St Félix of Fréjus (1788); A. C. S. Baring-Gould, Curious Myths of the Middle Ages, pp. 470 seq. (new ed., 1881); and J. C. Brunet, Manuel du libraire (vol. ii., 1862, s.v. Jean d'Arras).

MELVILLE, ANDREW (1545-1622), Scottish scholar, theologian and religious reformer, was the youngest son of Richard Melville (brother to Melville of Dysart), proprietor of Bouldy near Montrose, at which place Andrew was born on the 1st of August, 1545. His father fell at the battle of Pinkie (1547), fighting in the van of the Scottish army, and, his wife having died soon after, the orphan was cared for by his eldest brother Richard (1522-1575). At an early age Melville began to show a taste for learning, and his brother did everything in his power to give him the best education. The rudiments of Latin he obtained at the grammar school of Montrose, after leaving which he learned Greek for two years under Pierre de Marselliers, a Frenchman whom John Erskine of Dun had induced to settle at Montrose; and such was Melville's proficiency that on going to the university of St Andrews he excited the astonishment of his Masters by using the language of Greek, of which he had already learned the rudiments in his own time. On completing his course, Melville left St Andrews with the reputation of "the best poet, philosopher, and Grecian of any young master in the land." He then, in 1564, being nineteen years of age, set out for France to perfect his education at the university of Paris. He there applied himself to Oriental languages, but also attended the last course of lectures delivered by Turnebus in the Greek chair, as well as those of Peter Ramus, whose philosophical method and plan of teaching he afterwards introduced into the universities of Scotland. From Paris he proceeded to the Citadelle at Frankfort, to study civil law, and though only twenty-one he was apparently at once made a regent in the college of St Marceon. After a residence of three years, however, political troubles compelled him to leave France, and he went to Geneva, where he was welcomed by Theodore Beza, at whose instigation he was appointed to the chair of humanity in the academy of Geneva. In addition to his teaching, however, he also applied himself to studies in Oriental literature, and in particular acquired from Cornelius Bertram, one of his brother professors, a knowledge of Syriac. While he resided at Geneva the massacre of St Bartholomew's Day (1572) threw an immense number of Protestant refugees to that city, including several of the most distinguished French men of letters of the time. Among these were several men learned in civil law and political science, and their society increased Melville's knowledge of the world and enlarged his ideas of civil and ecclesiastical liberty. In 1574 Melville returned to Scotland, and almost immediately received the appointment of principal of Glasgow University, which had fallen into an almost ruinous state, the college having been shut and the students dispersed. Melville,
however, set himself to establish a good educational system. He enlarged the curriculum at the college, and established chairs in languages, science, philosophy and divinity, which were confirmed by charter in 1577. His fame spread through the kingdom, and students flocked from all parts of Scotland and even beyond it. The Duke of Gordon was one of the first to demand those who came for admission. He assisted in the reconstruction of Aberdeen University in 1575, and in order that he might do for St Andrews what he had done for Glasgow, he was appointed principal of St Mary's College, St Andrews, in 1580. His duties there comprehended the teaching, not only of theology, but of the Hebrew, Chaldee, Syriac and Rabbinical languages. The ability of his lectures was universally acknowledged, and he created a taste for the study of Greek literature. The reforms, however, which his new modes of teaching involved, and even some of his new doctrines, such as the non-infallibility of Aristotle, brought him into collision with other teachers in the university.

He was moderator of the General Assembly in 1582, and took part in the organization of the Church and the Presbyterian method. Troubles arose from the attempts of the court to force a system of Episcopacy upon the Church of Scotland (see Scotland, Church of), and Melville prosecuted one of the "tulchan" bishops (Robert Montgomery, d. 1600). In consequence of this he was summoned before the Privy Council in February 1583, and had to flee into England in order to escape an abscond charge of treason. The close of Melville's career, however, was not immediately over. After an absence of twenty months he returned to Scotland in November 1585, and in March 1586 resumed his lectures in St Andrews, where he continued for twenty years; he became rector of the university in 1590. During the whole time he protected the liberties of the Scottish Church against all encroachments of the government. That in the main he and his coadjutors were fighting for the constitutionally guaranteed rights of the Church is admitted by all candid inquirers (see in particular The History of England from 1603 to 1616, by S. R. Gardiner, vol. ii. p. x.). The chief charge against him is that his fervour often led him to forget the reverence due to an "anointed monarch." Of this, however, it is not easy to judge. Manners at that time were rougher than at present. When the king acted in an arbitrary and illegal manner he needed the reminder that though he was king over men he was only "God's silly vassal." Melville's rudeness (if it is to be called so) was the outburst of just indignation from a man zealous for the purity of religion and regardless of consequences to himself. In 1590 he was deprived of the rectorship, but was made dean of the faculty of divinity. The close of his career was at length brought about by James in characteristic fashion. In 1606 Melville and seven other clergymen of the Church of Scotland were summoned to London in order "that his majesty might treat with them of such things as would tend to settle the peace of the Church." The contention of the whole of these faithful men was that the only way to accomplish that purpose was a free Assembly. Melville delivered his opinion to that effect in two long speeches with his accustomed freedom, and, having shortly afterwards written a sarcastic Latin epigram on some of the ritual practised in the chapel of Hampton Court, and some eavesdropper having conveyed the lines to the king, he was committed to the tower, and detained there for four years. On regaining his liberty, and being refused permission to return to his own country, he was invited to fill a professor's chair in the university of Sedan, and there he spent the last eleven years of his life. He died at Sedan in 1622, at the age of seventy-seven.

See McCries, Andrew Melville (ed. 1819); Andrew Lang, History of Scotland (1902).

MELVILLE, ARTHUR (1818-1904). British painter, was born in Scotland, in a village of Haddingtonshire. He took up painting at an early age, and though he attended a night-school and studied afterwards in Paris and Grez, he learnt more from practice and personal observation than from school training. The remarkable colour-sense which is so notable a feature of his work, whether in oils or in water-colour, came to him during his travels in Persia, Egypt and India. Melville, though comparatively little known during his lifetime, was one of the most powerful influences in contemporary art, especially in his broad decorative treatment with under-colour. Though his vivid impressions of colour and movement are apparently recorded with feverish haste, they are the result of careful deliberation and selection. He was at his best in his water-colours of Eastern life and colour and his Venetian scenes, but he also painted several striking portraits in oils and a powerful colossal composition of "The Return from the Crucifixion" which remained unfinished at his death in 1904. At the Victoria and Albert Museum is one of his water-colours, "The Little Bull-Fight—Bravo, Toror" and another, "An Oriental Goatherd," is in the Weimar Museum. But the majority of his pictures have been absorbed by private collectors, who, however, set himself to establish a good educational system. He enlarged the curriculum at the college, and established chairs in languages, science, philosophy and divinity, which were confirmed by charter in 1577. His fame spread through the kingdom, and students flocked from all parts of Scotland and even beyond it. The Duke of Gordon was one of the first to demand those who came for admission. He assisted in the reconstruction of Aberdeen University in 1575, and in order that he might do for St Andrews what he had done for Glasgow, he was appointed principal of St Mary's College, St Andrews, in 1580. His duties there comprehended the teaching, not only of theology, but of the Hebrew, Chaldee, Syriac and Rabbinical languages. The ability of his lectures was universally acknowledged, and he created a taste for the study of Greek literature. The reforms, however, which his new modes of teaching involved, and even some of his new doctrines, such as the non-infallibility of Aristotle, brought him into collision with other teachers in the university. He was moderator of the General Assembly in 1582, and took part in the organization of the Church and the Presbyterian method. Troubles arose from the attempts of the court to force a system of Episcopacy upon the Church of Scotland (see Scotland, Church of), and Melville prosecuted one of the "tulchan" bishops (Robert Montgomery, d. 1600). In consequence of this he was summoned before the Privy Council in February 1583, and had to flee into England in order to escape an abscond charge of treason. The close of Melville's career, however, was not immediately over. After an absence of twenty months he returned to Scotland in November 1585, and in March 1586 resumed his lectures in St Andrews, where he continued for twenty years; he became rector of the university in 1590. During the whole time he protected the liberties of the Scottish Church against all encroachments of the government. That in the main he and his coadjutors were fighting for the constitutionally guaranteed rights of the Church is admitted by all candid inquirers (see in particular The History of England from 1603 to 1616, by S. R. Gardiner, vol. ii. p. x.). The chief charge against him is that his fervour often led him to forget the reverence due to an "anointed monarch." Of this, however, it is not easy to judge. Manners at that time were rougher than at present. When the king acted in an arbitrary and illegal manner he needed the reminder that though he was king over men he was only "God's silly vassal." Melville's rudeness (if it is to be called so) was the outburst of just indignation from a man zealous for the purity of religion and regardless of consequences to himself. In 1590 he was deprived of the rectorship, but was made dean of the faculty of divinity. The close of his career was at length brought about by James in characteristic fashion. In 1606 Melville and seven other clergymen of the Church of Scotland were summoned to London in order "that his majesty might treat with them of such things as would tend to settle the peace of the Church." The contention of the whole of these faithful men was that the only way to accomplish that purpose was a free Assembly. See McCries, Andrew Melville (ed. 1819); Andrew Lang, History of Scotland (1902).

MELVILLE, ARTHUR (1818-1904). British painter, was born in Scotland, in a village of Haddingtonshire. He took up painting at an early age, and though he attended a night-school and studied afterwards in Paris and Grez, he learnt more from practice and personal observation than from school training. The remarkable colour-sense which is so notable a feature of his work, whether in oils or in water-colour, came to him during his travels in Persia, Egypt and India. Melville, though comparatively little known during his lifetime, was one of the most powerful influences in contemporary art, especially in his broad decorative treatment with under-colour. Though his vivid impressions of colour and movement are apparently recorded with feverish haste, they are the result of careful deliberation and selection. He was at his best in his water-colours of Eastern life and colour and his Venetian scenes, but he also painted several striking portraits in oils and a powerful colossal composition of "The Return from the Crucifixion" which remained unfinished at his death in 1904. At the Victoria and Albert Museum is one of his water-colours, "The Little Bull-Fight—Bravo, Toror" and another, "An Oriental Goatherd," is in the Weimar Museum. But the majority of his pictures have been absorbed by private collectors, who, however,
friend among the literary men of America. His writings are numerous, and of varying merit; his verse, patriotic and other, is forgotten; and his works of fiction and of travel are of irregular execution. Nevertheless, few authors have been enabled so freely to introduce personal experiences into their books: in his first work, Typee: A Peep at Polynesian Life, or Four Months' Residence in a Valley of the Marquesas (1846), he described his escape from the cannibals; while in Omoo, a Narrative of Adventures in the South Seas (1847), White Jacket, or The World in a Man-of-War (1850), and especially Moby Dick, or The Whale (1851), he portrayed seafaring life and character with vigorous verisimilitude, sustained from personal knowledge equal to that of Cooper, Marryat or Clark Russell. But the records of adventure were followed by other tales so turgid, eccentric, opinoisive, and loosely written as to seem the work of another author. Melville was the product of a period in American literature when the fiction written by writers below Irving, Poe and Hawthorne was measured by humble artistic standards. He died in New York on the 28th of September 1891.

MELVILLE, JAMES (1536-1614), Scottish reformer, nephew of Andrew Melville (q.v.), was born on the 20th of July 1536. He was educated at Montrose and St Leonard's College, St Andrews. In the college he wrote his work, May owen Scottish, in which his uncle was principal, and within a year became one of the regents. When his uncle was appointed, in 1586, principal of the New (later, St Mary's) College, St Andrews, he was transferred to the chair of Oriental languages there. For three and a half years he lectured in the university, chiefly on Hebrew, but he had to flee to Berwick in May 1584 (a few months after his uncle's exile) to escape the attacks of his ecclesiastical enemy, Bishop Adamson. After a short stay there and at Newcastle-on-Tyne, and again at Berwick, he proceeded to London, where he joined some of the leaders of the Scottish Presbyterian party. The taking of Stirling Castle in 1587, in which he had ecclesiastical positions in the north, he returned to Scotland in November of that year, and was restored to his office at St Andrews. From 1586 to his death he took an active part in Church controversy. In 1586 he was moderator of the General Assembly and on several occasions represented his party in conferences with the court. Despite his antagonism to James's episcopal schemes, he appears to have won the king's respect. He answered, with his uncle, a royal summons to London in 1606 for the discussion of Church policy. The uncompromising attitude of the Kinmamen, though it was made the excuse for sending the elder to the Tower, brought no further punishment to James than easy detention within ten miles of Newcastle-on-Tyne. During his residence there it was made clear to him by the king's agents that he would receive high reward if he supported the royal plans. In 1613 negotiations were begun for his return to Scotland, but his health was broken, and he died at Berwick in January 1614.

Melville has left ample materials for the history of his time from the Presbyterian standpoint, in (a) correspondence with his uncle Andrew Melville (MS. in the library of the university of Edinburgh), and (b) a diary (MS. in the Advocates' Library, Edinburgh). The latter is written in a vigorous, fresh style, and is especially direct in its descriptions of contemporaries. His sketch of John Knox at St Andrews is one of his best passages. As a writer of verse he compares unfavourably with his uncle. All his pieces, with the exception of a "ribald supples" to King James, are written in Scots. He translated a portion of the Zodiacus vitae of Palingenus, and adapted some passages from Scaliger under the title of Description of the Spaniards Natural. His Spiritual Preparations of a Pastor to his People (1598), The Black Bassid, a lamentation for the kirk (1611), Thir may keip Counsell, give Twa be away, The Belief of the Singing Soul, David's Tragicke Fall, and a number of Sonnets show no originality and indifferent taste.

The Diary was printed by the Bannatyne Club in 1829, and by the Wodrow Society in 1842. Large portions of it are incorporated in David Calderwood's (1575-1650) History of the Kirk of Scotland (1688). For the life and works, see Colin, Thomas M'Crie's Life of Andrew Melville.

MELVILLE, SIR JAMES (1553-1617), Scottish diplomatist and memoir writer, was the third son of Sir John Melville, laird of Raith in the county of Fife, who was executed for treason in 1548. One of his brothers was Robert, 1st Baron Melville of Monimail (1527-1621). James Melville in 1549 went to France to become page to Mary Queen of Scots. Serving on the French side at the battle of St Quentin in 1557 Melville was wounded and taken prisoner. He subsequently carried out a number of diplomatic missions for Henry II. of France. On Mary's return to Scotland in 1561 she gave Melville a pension and an appointment in her household, and she employed him as special emissary to reconcile Queen Elizabeth to her marriage with Darnley. After the murder of Darnley in February 1567, Melville joined Lord Herries in boldly warning Mary of the danger of her projected marriage with Bothwell, and was only saved from the pillory by the courageous resolution of the queen. During the troubled times following Mary's imprisonment and abdication Melville conducted several diplomatic missions of importance, and won the confidence of James VI. when the king took the government into his own hands. Having been adopted as his heir by the reformer Henry Balnaves, he inherited from him, at his death in 1579, the estate of Halkhill in Fife; and he retired thither in 1603, refusing the request of James to accompany him to London on his accession to the English throne. At Halkhill Melville wrote the Memoirs of my Life, a valuable authority for the history of the period, first published by his grandson, George Scott, in 1683. Sir James Melville died at Halkhill on the 13th of November 1617. By his wife, Christina Boswell, he had one son and two daughters; the elder of these, Elizabeth, who married John Colville, de jure 3rd Baron Colville of Culross, has been identified with the authoress of a poem published in 1603, entitled Anie Goodie Dreams.

See the Memoirs mentioned above, of which the most modern edition is that prepared by T. Thompson for the Bannatyne Club (Edinburgh, 1827).

MELVIL VAN CARNBEE, PIETER, BARON (1816-1896), Dutch geographer, was born at the Hague on the 20th of May 1816. He traced his descent from an old Scottish family, originally, it is said, of Hungarian extraction. Destined for the navy, in which his grandfather Pieter Melvil van Carnbee (1743-1810) had been admiral, he imbibed a taste for hydrography and cartography as a student in the college of Medemblik, and he showed his capacity as a surveyor on his first voyage to the Dutch Indies (1835). In 1839 he was again in the East, and was attached to the hydrographical bureau at Batavia. With the assistance of documents collected by the old East India Company, he completed a map of Java in five sheets, accompanied by sailing directions (Amsterdam, 1842). He remained in the East till 1849 collecting materials for a chart of the waters between Sumatra and Borneo (two sheets, 1845 and 1846). On his return to Holland he was attached to the naval department with the charge of studying the history of the hydrography of the Dutch East Indies. He also undertook, in connexion with P. F. von Siebold, the publication of the Moniteur des Indes, a valuable series of scientific papers, mainly from his own pen, on the foreign possessions of Holland, which was continued for three years. In 1850 Melvil returned to India as lieutenant of the first class and adjutant to Vice-Admiral van den Bosch; and after the premature death of this commander he was again appointed keeper of the charts at Batavia. In 1853 he obtained exemption from active naval service that he might devote himself to a general atlas of the Dutch Indies. But in 1856 he fell a victim to climate, dying at Batavia on the 24th of October. In spite of delays in engraving, twenty-five sheets of the atlas were already finished, but it was not till 1862 that the whole plan, embracing sixty sheets, was completed by Lieut.-Colonel W. F. Versteeg. In 1843 Melvil received the decoration of the Netherlands Lion, in 1849 that of the Legion of Honour.

MEMBRANELLE, an organ in Ciliate Infusoria (q.v.), a flattened assemblage of adherent cilia, like the plates of Ctenophora (q.v.): such are arranged in a series in the adoral wreath of the Heterotrichaceae Oligotrichaceae and Hypotrichaceae and constitute the posterior girdle of Peritricha.
MEMEΛ, a town of Germany, in the kingdom of Prussia, the most northerly town of the German empire, 91 m. by rail N.E. of Königsberg, at the mouth of the Dange, and on the bank of a sound, called the Memeler Tief, which connects the Kurische Haff with the Baltic. Pop. (1905), 20,687. On the side next the sea the town is defended by a citadel and other fortifications, and the entrance to the harbour is protected by a lighthouse. Memel has been largely rebuilt since the destructive fire in 1854. It possesses iron-foundries, shipbuilding yards, breweries, distilleries, and manufactories of chemicals, soap and amber wares. By far the most important interest of the town, however, is its transit trade in timber and the grain and other agricultural products of Lithuania, and also herrings and other kinds of fish. The timber is brought by river from the forests of Russia, and is prepared for export in numerous saw-mills. The annual value of timber exported is above £1,000,000. A Prussian national memorial was unveiled here in the presence of the emperor William II. in September 1897.

Memel was founded in 1252 by Poppo von Osteran, grand master of the Teutonic order, and was at first called New Dortmund and afterwards Memelburg. It soon acquired a considerable trade, and joined the Hanseatic League. During the 13th, 14th and 15th centuries annually buried bodies on the hostile shore of Memel, which, as also happened in Lithuania, and also herrings and other kinds of fish. The timber is brought by river from the forests of Russia, and is prepared for export in numerous saw-mills. The annual value of timber exported is above £1,000,000. A Prussian national memorial was unveiled here in the presence of the emperor William II. in September 1897.

MEMEL, or NIEMEN, a river of Russia and Prussia, rising in the middle of the Russian government of Minsk at an altitude of 580 ft. and flowing generally west as far as Grodno. Thence it runs north to Kovno, separating Poland from Russia, and at Kovno it turns west again, still dividing Poland from Russia, until it enters the Prussian province of East Prussia, through which it flows west and north-west past Tilsit for a distance of 70 m. and finally enters the Kurisches Haff by several arms. Of these, those principally used for navigation are the Russ, and its chief branch the Atmat. The Russ is connected with the outlet of the Kurisches Haff at Memel by a canal, while another canal links the Gilge arm southward with the Pregel. Considerable quantities of timber are floated down the Memel, and large amounts of corn shipped down it and its navigable tributary the Villya. The lowlands of Tilsit are protected against inundation by dikes. Total length of the river, 490 m.; area of its basin, 34,950 sq. m. It is navigable for large vessels as far as Grodno.

See H. Koller, Memel, Pregel und Weichselstrom (2 vols., Berlin 1900); and Schickert, Wasserwege und Deichzünder in der Memelniederung (Königsberg, 1901).

MELING, HANS (c. 1430—1494), Flemish painter, whose art gave lustre to Bruges in the period of its political and commercial decline. Though much has been written respecting the rise and fall of the school which made this city famous, it remains a moot question whether that school ever truly existed. Like Rome or Naples, Bruges absorbed the talents which were formed and developed in humber centres. Jan Van Eyck first gained repute at Ghent and the Hague before he acquired a domicile elsewhere, and Memling, we have reason to think, was a skilled artist before he settled at Bruges. The annals of the city are silent as to the birth and education of a painter whose name was inaccurately spelt by different authors, and whose identity was lost under the various appellations of Hans and Hausse, or Memling, Memling, and Memlinc. But W. H. J. Weale mentions a contemporary document discovered in 1859, according to which Memling "drew his origin from the ecclesiastical principality of Mayence," and died at Bruges on the 11th of August 1494. He probably followed his apprenticeship at Mayence or Cologne, and later worked in the Netherland. He did not visit Bruges until about 1467, and certainly not as a wounded fugitive from the field of Nancy. The story is fiction, as is also the report that he was sheltered and cured by the Hospitalers at Bruges, and, to show his gratitude, refused payment for a picture he had painted. Memlinc did indeed paint for the Hospitalers, but he painted not one but many pictures, and he did so in 1470 and 1486, being probably known to his patrons of St John by many masterpieces even before the battle of Nancy.

Memling is only connected with military operations in a mediate and distant sense. His name appears on a list of subscribers to the loan which was raised by Maximilian of Austria to push hostilities against France in the year 1480. In 1477, when he is falsely said to have fallen, and when Charles the Bold was killed, he was under contract to furnish an altarpiece for the gild-chapel of the booksellers of Bruges; and this altarpiece, now preserved, under the name of the "Seven Griefs of Mary," in the gallery of Turin, is one of the fine creations of his riper age, and not inferior in any way to those of 1479 in the hospital of St John, which for their part are hardly less in communion with an idea of the master's power than the "Last Judgment" in the cathedral of Danzig. Critical opinion has been unanimous in assigning the altarpiece of Danzig to Memlinc; and by this it affirms that Memlinc was a resident and a skilled artist at Bruges in 1473; for there is no doubt that the "Last Judgment" was painted and sold to a merchant at Bruges, who shipped it there on board of a vessel bound to the Mediterranean, which was captured by a Danzig privateer in that very year. But, in order that Memlinc's repute should be so fair as to make his pictures purchasable, as this had been, by an agent of the Medici at Bruges, it is incumbent on us to acknowledge that he had furnished sufficient proofs before that time of the skill which excited the wonder of such highly cultivated patrons.

If it is characteristic that the oldest allusions to pictures connected with Memlinc's name are those which point to relations with the Burgundian court. The inventories of Margaret of Austria, drawn up in 1524, allude to a triptych of the "God of Pity" by Rogier van der Weyden, of which the wings containing angels were by "Master Hans." But this entry is less important as afford testimony in favour of the preservation of Memling's work in Bruges, it is incumbent on us to acknowledge that he had furnished sufficient proofs before that time of the skill which excited the wonder of such highly cultivated patrons.

The oldest form in which Memling's style is displayed, or rather in that example which represents the Baptist in the gallery of Munich, we are supposed to contemplate an effort of the year 1470. The finish of this piece is scarcely surpassed, though the subject is more important, by that of the "Last Judgment" of Danzig.
MEMMINGEN—MENNON

But the latter is more interesting than the former, because it tells us how Memlinc, long after Roger's death and his own settlement at Bruges, preserved the traditions of sacred art which had been applied in the first part of the century by Rogier van der Weyden to the scenes of the Life of Christ. All through the Thirty Years' War it was actually occupied by the Swedes and the Imperialists. In May 1800 the French gained a victory over the Austrians near Memmingen.

See Dobel, Memminger im Reformationssteller (Augsburg, 1877—1874), and Claus, Memminger Chronik, 1826—1892 (Memminger, 1894).

MEMMUS, GAIUS (incorrectly called Genellus, "The Twin"). Roman orator and poet, tribune of the people (66 B.C.), friend of Lucretius and Catullus. At first a strong supporter of Pompey, he quarrelled with him, and went over to Caesar, whom he had previously attacked. In 54, as candidate for the consulship, he lost Caesar's support by revealing a scandalous transaction in which he and his fellow candidate had been implicated (Cic. Ad Att. iv. 15—18). Being subsequently condemned for illegal practices at the election, he withdrew to Athens, and afterwards to Mytilene. He died about the year 40. He is remembered chiefly because it is to him that Lucretius addressed the De rerum natura, perhaps with the idea of making him a convert to the doctrines of Epicurus. It appears from Cicero (Ad Fam. xiii. 1) that he possessed an estate on which were the ruins of Epicurus' house, and that he had determined to build on the site a house for himself. According to Ovid (Trist. ii. 433) he was the author of erotic poems. He possessed considerable oratorical abilities, but his contempt for Latin letters and preference for Greek models impaired his efficiency as an advocate (Cic. Brut. 70).

Another Gaius Memmius, tribune in 111 B.C., attacked the aristocrats on a charge of corrupt relations with Jugurtha. Memmius subsequently stood for the consulship in 99, but was slain in a riot stirred up by his rival the praetor Glaucia. Sallust describes him as an orator, but Cicero (De oratore, ii. 59, 70) had a poor opinion of him.

MENNON, in Greek mythology, son of Tithonus and Eos (Dawn), king of the Aethiopians. Although mentioned in Hesiod and the Odyssey, he is rather a post-Homeric hero. After the death of Hector he went to assist his uncle Priam against the Greeks. He performed prodigies of valour, but was slain by Achilles, after he had himself killed Antilochus, the son of Nestor and the friend of Achilles. His mother, Eos, removed his body from the field of battle, and it was said that Zeus, moved by her tears, bestowed immortality upon him. According to another account, Memnon was engaged in single combat with Achilles, to whom his followers forced him to withdraw. Achilles then challenged the warriors who had time to come to his aid (Dictyus Cretensis iv. 6; Quintus Smyrnaeus ii.; Pindar, Pythia, vi. 31). His mother wept for him every morning, and the early dew-drops were said to be her tears. His companions were changed into birds, called Memnonides, which came every year to fight and lament over his grave, which was variously located (Ovid, Metam. xiii. 526—622; Pausanias x. 31). The story of Memnon was the subject of the lost Aethiopis of Arctinus of Miletus; the chief source from which our knowledge of him is derived is the second book of the Pseudo-Phoronymos of Quintus Smyrnaeus (itself probably an adaptation of the works of Arctinus and others), in which his exploits and death are described at length. As an Aethiopian, Memnon was described as black, but was noted for his beauty. The fight between Achilles and Memnon was often represented by Greek artists, as on the chest of Cypselus, and more than one Greek play was written hearing his name as a title. In later times the tendency was to regard Memnon as a real historical figure. He was said to have built the royal citadel of Susa, called after him the Memnonion, and to have been sent by Teutamis, king of Assyria, to the assistance of his vassal Prium (Diod. Sic. ii. 22). In Egypt, the name of Memnon was connected with the colossal statues of Amenophis (Amenhotep) III near Thebes, two of which still remain. The more northerly of these was partly destroyed by an earthquake (27 B.C.) and the upper part thrown down. A curious phenomenon then occurred. Every morning, when the rays of the rising sun touched the statue, it gave forth musical sounds, like the
MEMNON OF RHODES—MEMPHIS

omen noise or the sharp twang of a harp-string. This was supposed to be the voice of Memnon responding to the greeting of his mother Eos. After the restoration of the statue by Septimius Severus (A.D. 176) the sounds ceased. The sound, which has been heard by modern travellers, is generally attributed to the passage of the air through the pores of the stone, chiefly due to the change of temperature at sunrise. Others have held that it was a device of the priests. Strabo (xvii. 816), the first to mention the sound, declares that he himself heard it, and Pausanias (i. 42, 3) says "one would compare the sound most nearly to the broken chime of a harp for a lull." (Juvenal xv. 5, with Memnon, "Pytho"); Tacitus, Annals, ii. 61.

The supporters of the solar theory look upon Memnon as the son of the dawn, who, though he might vanish from sight for a time, could not be destroyed; hence the immortality bestowed upon him by Zeus. He comes from the east, that is, the land of the rising sun. On early Greek vases he is represented as borne through the air; this is the sun making his way to his place of departure in the west. Both Susa and Egyptian Thbes, where there was a Memnonia or temple in honour of the hero, were centres of worship. With the mother of Memnon, is so transparently the morning, that her child must rise again as surely as the sun reappears to run his daily course across the heavens. (G. W. Cox, Mythology and Religion of the Egyptians, p. 267).

See J. A. Letronne, La Statue vocale de Memnon (1833); C. R. Lepsius, Briefe aus Egypten (1852); "The Voice of Memnon" in Edinburgh Review (July 1886); article by R. Holland in Roscher's Lexicon der mythologie.

MEMNON OF RHODES, brother of Mentor (q.v.), with whom he entered the services of the rebellious satrap Artabazus of Phrygia, who married his sister. Mentor after the conquest of Egypt rose high; he was represented as borne through the air; he had taken refuge with Artabazus at the Macedonian court, became a zealous adherent of the Persian king; he assisted Mentor in subduing the rebellious satraps and dynasties in Asia Minor, and succeeded him as general of the Persian troops. In the pseudo-Aristotelian Oeconomici, ii. 28, stories are told of his methods of obtaining money and evading his obligations; thus he extorted a large sum of money from the conquered inhabitants of Lampsacus and cheated his soldiers out of a part of their pay. He owned a large territory in eastern Troas (Arrian i. 17, 8; Strabo xiii. 587). He gained some successes against Philip II. of Macedon in 336 (Diod. vii. 6; Polyzen, v. 44, 4, 5) and commanded the Persian army against Alexander's invasion. Convinced that it was impossible to meet Alexander in a pitched battle, his plan was to lay waste the country and retire into the interior, meanwhile organizing resistance on sea (where the Persians were far superior to the Macedonians) and carrying the war into Greece. But his advice was overruled by the Persian satraps, who forced him to fight at the Granicus. After his defeat he tried to organize the maritime war and occupied the Greek islands, but in the beginning of 333 he fell ill and died (Arrian ii. 1, 1).

MEMORANDUM OF ASSOCIATION, in English company law, a document subscribed to by seven or more persons associated for any lawful purpose, by subscribing to which, and otherwise complying with the requirements of the Companies Acts in respect of registration, they may form themselves into an incorporated company, with or without limited liability (see Company).

MEMORIAL DAY (or Decoration Day), a holiday observed in the northern states of the United States on the 36th of May, in honour of soldiers killed in the American Civil War, and especially for the decoration of their graves with flags and flowers. Before the close of the Civil War the 36th of May was thus celebrated in several of the southern states; in the North there was no fixed day commonly celebrated until 1868, when (on the 5th of May) Commander-in-Chief John A. Logan, of the Grand Army of the Republic, issued a general order designating the 30th of May 1868 "for the purpose of strewn with flowers or otherwise decorating the graves of comrades who died in defense of their country during the late rebellion"; Logan did this because "that it will be kept up from year to year." In 1882 the Grand Army urged that the "proper designation of May 30 is Memorial Day"—not Decoration Day. Rhode Island made it a legal holiday in 1874, Vermont in 1876, and New Hampshire in 1877; and by 1910 it was a legal holiday in all the states and territories save Alabama, Alaska, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina and Texas. In Virginia the 30th of May is observed as a Confederate Memorial Day. The 3rd of June (the birthday of Jefferson Davis) is observed as Confederate Memorial Day in Louisiana and Tennessee; the 26th of April in Alabama, Florida, Georgia and Mississippi; and the 10th of May in North Carolina and South Carolina.

MEMPHIS, the capital of Egypt through most of its early history, now represented by the rubbish mounds at Bedrêshên on the W. bank of the Nile 14 m. S. of Cairo. As the chief seat of the worship of Ptah, the artesian god (Hapheastus), Memphis must have existed from a very remote time. But its greatness probably began with Menes (q.v.), who united the kingdoms of Upper and Lower Egypt, and is said to have secured the site for his capital near the border of the two lands by diverting the course of the river eastward. Memphis was the chief city of Memphis was still important though declining at this period as "the white walls" or the "white wall," a name which clung to its citadel down to Herodotus's day. The residence here of Pepi I. of the VIth Dynasty, as well as his pyramid in the necropolis, was named Mn-nef, and this gradually became the usual designation of the whole city, becoming Menfi, Membi in late Egyptian, i.e. Memphis. It was also called Hâkepht, "Residence of the ka of Ptah," and this name furnishes a possible origin for that of Egypt (Aâyêptô). Various dynasties had their ancestral seats elsewhere and individual kings built their palaces and pyramids at Memphis in turn. Memphis has been generally the centre of the government and the largest city in Egypt until the New Empire (Dyns. XVIII—XX.), when Thebes took the lead. In the succeeding period it regained its ancient position. The government of the Persian satrap was seated in Memphis. After the conquest of Alexander the city quickly lost its supremacy to his new foundation, and although it remained the greatest native centre, its population was less than that of Alexandria. In the time of Strabo (xvii. 87) it was the second city of Egypt, inferior only to Alexandria, and with a mixed population like the latter. Memphis was still important though declining at the time of the Moslem conquest. Its final fall was due to the rise of the Arabic city of Fostât on the right bank of the Nile almost opposite the northern end of the old capital; and its ruins, so far as they still lay above ground, gradually disappeared, being used as a quarry for the new city, and afterwards for Cairo. The remains of "Menfi" were still imposing late in the 12th century, when they were described by 'Abdallâth. Now the ruins of the city, the great temple of Ptah, the dwelling of Apis, and the palaces of the kings, are traceable only by a few stones among the palm trees and fields and heaps of rubbish. But the necropolis has been to a great extent protected by the accumulations of blown sand. Pyramids of the Old and Middle kingdoms form a chain 20 m. long upon the edge of the valley from Gizâ to Dahshur. At Saqqara, opposite Memphis itself, the step-pyramid of Zoser of the IIIrd Dynasty, several pyramids of the IVth and Vth Dynasties, and innumerable mastaba-tombs of the Old Kingdom, are crowded together in the cemetery. Later tombs are piled upon and cut through the old ones. One of the chief monuments is the Sarapeum or sepulchre of the Apis bulls, discovered by Mariette in 1851. From 1905 J. E. Quenell was charged by the Service des Antiquités solely with the excavations in this vast necropolis. His principal discovery has been the extensive remains of the Coptic monastery of St Jeremias, with remarkable sculptures and frescoes. Flinders Petrie began the systematic exploration of the ruins of Bedrêšên, and in three seasons cleared up much of the topography of the ancient city, identifying the mound of the citadel and palace, a foreign quarter, &c. Among his finds not the least interesting is a large series of terra-cotta heads representing the characteristic features of the foreigners who thronged the bazaars of Memphis. They date from the Persian rule down to
MEMPHIS—MENA, JUAN DE

the Ptolemaic period and are evidently modelled by Greek workmen. In the Old Testament Memphis is mentioned under the names of Moph (Hos. ix. 6) and Noph (Isa. xix. 13; Jer. ii. 16; Ezek. xxx. 13, 16).

MEMPHIS, a port of entry and the largest city of Tennessee, U.S.A., and the county-seat of Shelby county, on the Mississippi river, in the S.W. corner of the state. Pop. (1860), 22,625; (1870), 49,226; (1880), 33,952; (1890), 64,495; (1900), 102,320, of whom 51,260 were foreign-born and 49,610 were negroes; (1910 census) 111,105. It is served by the Chicago, Rock Island & Pacific, the St Louis & San Francisco, the Illinois Central, the Southern, the Louisville & Nashville, the Nashville, Chattanooga & St Louis, the St Louis South-Western, the St Louis, Iron Mountain & Southern and the Yazoo & Mississippi Valley railways, and by steamboats on the Mississippi.

The river is spanned here by a cantilever railway bridge 1805 ft. long, completed in 1892. The city is finely situated on the fourth Chickasaw Bluffs, more than 40 ft. above high water; the streets are broad, well paved and pleasantly shaded; and a broad levee over 100 ft. deep, with water at 5 ft. Square, in the heart of the city, are many fine old trees and a bust of President Andrew Jackson. In 1900 the city had about 1000 acres of parks and 11 ½ m. of parkways, besides two race-courses. Overton Park has beautiful playgrounds and a good zoological collection. Five miles from Memphis is a National Cemetery. Among the prominent buildings are the United States Government building, the court house, Cotton Exchange, Business Men's Club, Goodwyn Institute, containing an audotorium and the public library, the Cossert Free Library, Grand Opera House, Lyceum Theatre, Auditorium, Gayoso Hotel, Memphis Evening Scimitar building, the original building of the Memphis Press, the Equitable building, Memphis Trust building, Tennessee Trust building, the Bank of Commerce, Woman's building (containing offices for business women), Masonic Temple, Odd Fellows' building and the Commercial Appeal building. Among educational institutions are the College of Christian Brothers (Roman Catholic, opened in 1871), Memphis Hospital Medical College, College of Physicians and Surgeons, Hannibal Medical College for negroes and Le Moyne Normal Institute, also for negroes. Memphis is the see of a Protestant Episcopal bishopric. The city is supplied with water from a spring more than eighty artesian wells, having an average depth of about 400 ft.

Owing to its situation at the head of deep water navigation on the Mississippi, Memphis has become a leading commercial city of the southern states; its trade in cotton, lumber, groceries, mules and horses is especially large. The city also manufactures large quantities of cotton-seed oil and cake, lumber, flour and grist-mill products, foundry and machine-shop products, confectionery, carriages and wagons, paints, furniture, bricks, cigars, &c. The Illinois Central and the St Louis & San Francisco railways have workshops here. The total value of the city's manufactures increased from $31,244,528 in 1890 to $71,923,459 ($14,233,483 being factory product) in 1900, and to $21,346,817 (factory product) in 1905, an increase of 50% over the value of the factory product in 1900.

Chickasaw Bluffs were named from the Chickasaw Indians, who were in possession when white men first came to the vicinity. Late in the 17th century the French built a fort on the site of Memphis, and during most of the 18th century this site was held either by the French or the Spanish. In 1797 it passed into the possession of the United States. By a treaty of the 19th of October 1818, negotiated by General Andrew Jackson and General Isaac Shelby, the Chickasaws ceded all their claims east of the Mississippi, and early in 1818 Memphis was laid out in accordance with an agreement entered into by John Overton (1766–1833), Andrew Jackson and James Winchester (1752–1826), the proprietors of the land. Its name was suggested from the similarity of its situation on the Mississippi to that of the Egyptian city on the Nile. Memphis was incorporated as a town in 1827, and in 1849 was chartered as a city. Near Memphis, on the 6th of June 1862, a Union fleet of 9 vessels and 68 guns, under Captains Chauncey (1785–1877), defeated a Confederate fleet of 8 vessels and 28 guns under Commander J. E. Montgomery after a contest of little more than one hour, three of the Confederate vessels being destroyed and four of them captured, and from this victory until the close of the war the city was in possession of the Union forces. In August 1864, however, a Confederate force under General N. B. Forrest raided it and captured several hundred prisoners. The decrease of population between 1870 and 1880 was due to the ravages of yellow fever in 1873, 1878 and 1879. The epidemic of 1873 resulted in over two thousand deaths, and that of 1878, in a total of 5150, of whom 4250 were whites and 900 negroes. At the return of the fever in 1879 better care and strict quarantine arrangements prevailed, but there were 407 deaths. During the epidemics of 1878 and 1879 fully two-thirds of the population fled from the city, many of whom died of the fever at other places, and a still larger number did not return. For three months during each year business was suspended, and all ingress or egress except for the most necessary purposes was forbidden. The city was left almost bankrupt, and as a means of relief the legislature, by the terms of the state in January 1879 repealed the city's charter, and, assuming exclusive control of its finances, it constituted it simply a "taxing district," placing its government in the hands of a "legislative council." This anomalous proceeding was declared constitutional by the supreme court of Tennessee.

Subsequently the streets were cleansed and repaved, an improved sewer system was put in operation, and the water supply was obtained from artesian wells. In 1891 a new city charter was obtained, and in 1907 the "Houston plan" (see Houston, Texas) was adopted for Memphis by the state legislature. The act, however, was declared unconstitutional by the state supreme court, and in 1909 a new charter on the Houston plan was adopted by the legislature, to become effective on the 1st of January 1910, providing for a government by five commissioners, each having charge of a separate department.

See J. M. Keating. *History of the City of Memphis and Shelby County, Tennessee* (Syracuse, 1888); James Thelan, *History of Tennessee* (Boston, 1886).

MENA, JUAN DE (1411–1456), Spanish poet, was born at Córdova in 1411. In his twenty-fourth year he went to the university at Salamanca, and studied later at Rome. His scholarship obtained for him the post of Latin secretary at the court of Castile; subsequently he became historiographer to John II. and magistrate at Córdova. According to the *Epicedio* of Valerio Francisco Romero, Mené died from natural causes in 1456; popular tradition, however, ascribes his death to a fall from his mule. Though nominally the king's chronicler, Mené had no share in the *Crónica de Don Juan II.*; the statement that he wrote the first act of the *Cataleina* (q.v.) is rejected; but three authentic specimens of his curious prose exist in the commentary to his dull poem entitled *La Coronación o Calamanciones* in the *Híada en romance* (an abridged version of Homer), and in the unpublished *Memorias de algunos linajes antiguas é nobles de Castilla.* He is conjectured to be the author of the satirical *Coplas de la panadería*; but, apart from the fact that these verses are ascribed by Argote de Molina to Íñigo Ortiz de Zúñiga, they are distinct with a tart humour of which Mené was destitute. His principal work is his allegorical poem, *El Laberinto de Fortuna,* dedicated to John II.; in the oldest manuscripts it consists of 200 stanzas, but three more stanzas were added to it later, and hence the alternative, popular title of *Las Trescientas.* The *Laberinto* is modelled on Dante, and further contains reminiscences of the *Roman de la rose,* as well as episodes borrowed from Virgil and Lucan. It is marred by excessive emphasis and pedantic diction, and the *arte mayor* measure in which it is written is monotonous; but many octaves are of such excellence that the *arte mayor* metre continued in fashion for nearly a
MENA, PEDRO DE—MENAHEM

century. The poem, as a whole, is tedious; yet its dignified expression of patriotic spirit has won the admiration of Spaniards from Cervantes' time to our own.

A critical edition of the Laborinto has been issued by R. Fouc'hé-Delbos (Macon, 1904).

MENA, PEDRO DE (d. 1603), Spanish sculptor, was born in Adra. He was a pupil of his father as well as of Alonzo Cano. His first conspicuous success was achieved in work for the convent El Angel at Granada, including figures of St Joseph, St Antony of Padua, St Diego, St Pedro Madanela, St Francis and Santa Clara. In 1628 he signed a contract for sculptural work on the choir stalls of the cathedral at Malaga—this work extending over four years. Other works are, statues of the Madonna and child and of St Joseph in Madrid, the polychromatic figures in the church of St Isidoro, the Magdalena and the Gertrudis in the church of St Martin (Madrid), the crucifixion in the Nuestra Senora de Gracia (Madrid), the statue of St Francis of Assisi in Toledo, and of St Joseph in the St Nicholas church in Murcia. Between 1675 and 1679 Mena worked at Cordova. About 1680 he was in Madrid, where he executed a number of statues (seated) for St Domitian. Mena died in Malaga in 1693. He and Mora (q.v.) may be regarded as artistic descendants of Montafes and Alonzo Cano, but in technical skill and the expression of religious motive his statues are unsurpassed in the sculpture of Spain. His feeling for the nude was remarkable. Like his immediate predecessors he excelled in the portrayal of contemplative figures and scenes; Mena's drawing of Santiago leaping upon his charger is good, and the carving admirable, but the necessary movement for so spirited an action is lacking.

See R. Haendelke, Studien zur Geschichte der spanischen Plastik (Strassburg, 1900).

MENABREA, LUIGI FEDERICO, Marquis of Valdora (1800-1866), Italian general and statesman, was born at Chambéry on the 4th of September 1800. He was educated at the university of Turin, where he qualified as an engineer and became a doctor of mathematics. As an officer of engineers he represented Cavour in 1831 at the fortress of Bardo. He then became professor of mechanics and construction at the military academy and at the university of Turin. King Charles Albert sent him in 1848 on diplomatic missions to secure from Napoleon and Parma to Sardinia. He entered the Piedmontese parliament, and was attached successively to the Ministries of War and Foreign Affairs. He belonged to the right centre, and until the events of 1859 he believed in the possibility of a compromise between the Vatican and the state. He was major-general and commander-in-chief of the engineers in the Lombard campaign of 1859. He superintended the siege works against Peschiera, was present at Palestro and Solferino, and repaired the fortifications of some of the northern fortresses. In 1860 he became lieutenant-general and conducted the siege of Gaeta. He was appointed senator and received the title of count. Entering the Ricarsi cabinet of 1861 as minister of marine, he held the portfolio of public works until 1864 in the succeeding Farini and Minghetti cabinets. After the war of 1866 he was chosen as Italian plenipotentiary for the negotiation of the treaty of Prague and for the transfer of Venetia to Italy. In October 1867 he succeeded Rattazzi in the premiership, and was called upon to deal with the difficult situation created by Garibaldi's invasion of the Papal States and by the catastrophe of Mentana. Menabrea disavowed Garibaldi and instituted judicial proceedings against him; but in negotiations with the French government he protested against the retention of the temporal power by the pope and insisted on the Italian right of interference in Rome. He was in the secret of the direct negotiations between Victor Emmanuel and Napoleon III. In June 1869, and refused to entertain the idea of a French alliance unless Italy were allowed to occupy the Papal States, and, on occasion, Rome itself. On the eve of the assembly of the Oecumenical Council at Rome Menabrea reminded the Italian government of its zimbres and any measures directed against Italian institutions. He withdrew from seminary students in 1869 the exemption from military service which they had hitherto enjoyed. Throughout his term of office he was supported by the finance minister Count Cambry Digny, who forced through parliament the grist tax proposed by Quintino Sella, though in an altered form from the earlier proposal. After a series of changes in the cabinet, and many crises, Menabrea resigned in December 1869 on the election of a new chamber in which he did not command a majority. He was made marquis of Valdora in 1875. His successor in the premiership, Giovanni Lanza, in order to remove him from his influential position as aide-de-camp to the king, sent him to the menage where he remained until in 1882 he replaced General Cialdini at the Paris Embassy. Ten years later he withdrew from public life, and died at Saint Capon on the 24th of May 1896.

MÉNAGE, GILLES (1673-1692), French scholar, son of Guillaume Ménage, king's advocate at Angers, was born in that city on the 15th of August 1673. A tenacious memory and an early enthusiasm for learning carried him speedily through his literary and professional studies, and he practised at the bar at Angers as early as 1834. In the same year he pleaded several causes before the parlement of Paris, but illness induced him to abandon the legal profession for the church. He became prior of Montdidier without taking holy orders, and lived for some years in the household of Cardinal de Retz (then coadjutor to the archbishop of Paris), where he had leisure for literary pursuits. Some time after 1648 he quarrelled with his patron and withdrew to a house in the cloister of Notre-Dame, where he gathered round him on Wednesday evenings those literary assemblies which he called " Mercurelles." Chapelain, Pellisson, Comart, Sarrazin and Du Bos were among the habitués. He was admitted to the Della Crusca Academy of Florence, but his caustic sarcasm led to his exclusion from the French Academy. Ménage made many enemies and suffered under the satire of Boileau and of Molière. Molière immortalized him as the pedant Vadius in Les Femmes savantes, a portrait Ménage pretended to ignore. He died in Paris on the 23rd of July 1692.

Of his works the following may be mentioned: Poema la latina, gallica, grece, et italica (1696); Origini della lingua italiana (1669); Dictionnaire etymologique (1650 and 1670); Observations sur la langue française (1672-1676), and Anti-Bailleul (1690).

MENAGERIE, a collection of wild animals kept for show or exhibition. The word is particularly applied to travelling exhibitions of wild animals, attached to a circus or other show, "zoological gardens" being the term generally applied to large stationary and permanent exhibitions, arranged on a systematic and scientific system. From the French menage, Lat. mansionarium, mansio, house, cf. " manage ", originally meant the administration of a household or farm, with special reference to the live stock.

MENAHEM (Hebrew for "consoler"), a king of Israel. He was the son of Gadi (i.e. perhaps, a man of Gad), and during the disturbances at the death of Jeroboam II. seized the throne and reigned ten years (2 Kings xv. 14-18). The scene of his revolt was Tirzah, the old seat of the kings of Israel between Jeroboam I. and Omri (which period the present closely resembles), and it was only after perpetrating nameless cruelties at Tappuah1 on the border of Ephraim and Mannasseh that the counter revolt of Shallum, son of Jabelsh (perhaps a Gileadite), was suppressed. Towards the end of his reign Tiglath-Pileser IV. marched against north Syria, and among his tributaries mentions Menahem2 together with Rezin of Damascus, and kings of Tyre, Gebal, &c. (c. 738 B.C.). According to the Old Testament account the Assyrian king even advanced against Israel, and only withdrew in consideration of a tribute amounting to about 40,000,000 shekels.1 A thousand talents (i.e. about 3,000,000 shekels) was raised by assessing every wealthy person at 50 shekels. The act was hardly popular, and the internal troubles which he had quelled

1 Scarcely Tishphah (2 Kings xv. 16) on the Ephrathites.
2 The identification of the Israelite king with Me-ni-hi-(im)-ni of Sa-me-rim-ai on the Ass. inscription has been unnecessarily doubted.
broke out again at or shortly after his death. The Gileadites again conspired, and having slain his son Pekahiah set up Pekah the son of Remaliah in his place.1 This meant a return to an anti-Assyrian policy. (See Ahab.)

MENAI STRAITS, a channel of the Irish Sea, separating Anglesea from Carnarvonshire, N. Wales, extending 14 m. from Beaumaris to Abermenai, and varying in breadth from 200 yds. to 2 m. It is famous for the suspension and tubular bridges which cross it. The suspension bridge carries the Holyhead road from Bangor. Designs were prepared by T. Telford. It was begun in 1819; the first chain carried over in April 1825; the last in July of the same year, and the bridge opened to the public the 30th of January 1826. The cost was £120,000. The length of the chains (from rock-fastenings) is 1715 ft., and between the piers 500 ft.; the length of the roadway between the piers of the tubular bridge was deposited in its place on the 9th of November 1849, the last on the 13th of September 1850. The total cost was £621,865. The engineer of the tubular bridge was Robert Stephenson, who was assisted by Sir William Fairbairn and Eaton Hodgkinson.

MENAM, or Me Nam (literally the *mother water* or *main river*), a river of Siam, the chief highway of the interior, on whose yearly rise and fall depends the rice crop of Lower Siam. Rising in the Lao or Siamese Shan state of Nan, at a height of 1400 ft. upon the shoulders of the mountain mass of Doi Luang, it is first known as the Nan Nong (as a village of that name. As the Nam Nan, still a mountain stream, it flows southward through the state so named between high forested ranges, and, notwithstanding the frequent rapids along its course, the natives use it in dug-outs for the transport of hill produce. From Utrarat, where it leaves the hills of the Lao country, it flows southward through the plain of Lower Siam, and is navigable for flat-bottomed native craft of considerable capacity. It is here known as the Nam, or Menam Chial. Below Chial the river flows through forest and swamp, the latter providing vast overflow basins for the yearly rise in the level of the river. They were found by the British in the middle of the fall of the river after the rains. Below Pitsunalok the waters of the Menam Yom, the historic river of Siam, upon which two of its ancient capitals, Savankalok and Sukotai, were situated, meander by more than one tortuous clayey channel to the main river, and combine to form the Nam Po. At Paknam Po the main western tributary comes in, the shallow Me Ping, the river of Raheng and Chiang Mai, bringing with it the waters of the Me Wang. As the chief duty-station for teak, which is floated in large quantities down all the upper branches of the river and as a place of transshipment for both, Paknam Po is an important and growing town. From this point southwards the river winds by many channels through the richest and most densely populated portion of Siam. About Chai nat the Tachin branches off, forming the main western branch of the Menam, and falling into the gulf at a point about 24 m. west of the bar of the main or Bangkog river. At Ayuthia, another of the ancient capitals of Siam, the Nam Sak flows in from the north. Except for some affording communication with the rich tobacco district of Petchabun, and draining the western slopes of the Korat escarpment.

MENANDER (342–201 B.C.), Greek dramatist, the chief representative of the New comedy, was born at Athens. He was the son of well-to-do parents; his father Diopolites is identified by some with the Athenian general and governor of the Thracian Chersonese known from the speech of Demosthenes De Ceresono. He doubtless derived his taste for the comic drama from his uncle Alexis (q.v.). He was the friend and associate, if not the pupil, of Theophrastes, and was on intimate terms with Demetrius of Phalerum. He also enjoyed the patronage of Ptolemy Soter, the son of Lagus, who invited him to his court. But Menander, preferring independence and the company of his mistress Glyceria in his villa in the Peiraicus, refused. According to the note of a scholar on the Ibis of Ovid, he was drowned while bathing; his countrymen built him a tomb on the road leading to Athens, where it was seen by Pausanias.

A well-known statue in the Vatican, formerly thought to represent Marcus, is now generally supposed to be Menander (although some distinguished archaeologists dispute this), and has been identified with his statue in the theatre at Athens, also mentioned by Pausanias.

Menander was the author of more than a hundred comedies, but only gained the prize eight times. His rival in dramatic art and also in the affections of Glyceria was Philemon (q.v.), who appears to have been more popular. Menander, however, believed himself to be the better dramatist, and, according to Aulus Gellius, used to ask Philemon: "Don't you feel ashamed whenever you gain a victory over me?" According to Caesarius Calacte Aphthia (Porphyry in Eusebius, Praep. h. I, x. 3, 15) he was guilty of plagiarism, his Δεσποτάμων being taken bodily from the Ολωντάς of Antiphanes. But, although he attained only moderate success during his lifetime, he subsequently became the favourite writer of antiquity. Copies of his plays were known to Suidas and Eustathius (10th and 11th centuries), and twenty-three of them, with commentary by Psellus, were said to have been in existence at Constantinople in the 10th century. He is praised by Plutarch (Comparison of Menander and Aristophanes) and Quintillian (Instit. x. l. 69), who accepted the tradition that he was the author of the speeches published and imitated by Menander and imitator of Euripides, he resembles him in his keen observation of practical life, his analysis of the emotions, and his fondness for moral maxims, many of which have become proverbial: "The property of friends is common," "Whom the gods love die young," "Evil communications corrupt good manners" (from the Thais, quoted in I Cor. xv. 33). These maxims (chiefly monostichs) were afterwards collected, and, with additions from other sources, were edited as Μενάνδρου γνώμαι μορόστοι, a kind of moral textbook for the use of schools.

There are three Menander, Audria, Heautontimorumenos and Adelphi of Terence (called by Caesar "dimitiatus Menander") were avowedly taken from Menander, but some of them appear to be adaptations and combinations of more than one play; thus, in the Adria were combined Menander's Δεσποτάμων and Πέρσσπη, in the Ευνουχος the Ευνοχως and Κάλες, while the Αδελφή was compiled partly from Menander and partly from Diphilus. The original of Terence's Hecyra (as of the Phormio) is generally supposed to be, not Menander, but Apollodorus of Carystus. The Bacchides and Stichus of Plautus were probably based on Menander's Δεσποτάμων and Φίλολογος, but the Poenulus does not seem to be from the Καραγγόνος, nor the Μοσταρία from the Φαέτων, in spite of the similarity of titles. Caecilius Statius, Luscius Lavinius, Turpilius and Atellius also imitated Menander. He was further credited with the authorship of some epigrams of doubtful
MENANDER

authenticity; the letters addressed to Ptolemy Soter and the discourses in prose on various subjects mentioned by Suidas are probably spurious.

Till the end of the 19th century, all that was known of Menander was the material gathered in *Ptolemy* (1888) and T. Kock, *Comentum* (1888). They consist of some 150 verses or parts of verses, in addition to a considerable number of fragments, especially as preserved by the Graeco-Bactrian and Graeco-Indian coins, with bilingual legends (Greek and Kharoshthi, see BACTRIA).

Apollodotus, who must have been the earlier of the two kings, bears the titles Soter, Philopator, and "Great King"; Menander, who must have reigned a long time, as his portrait is young on some coins and old on others, calls himself Soter and "Just" (bikatos). Their reigns may be placed about 140-80 B.C. Menander appears in Indian traditions as Milinda; he is praised by the Buddhists, whose religion he is said to have adopted, and who in the Milinda-pañcha or Milinda Panho (see below), the earlier of the two Milindas, is blamed for having been tricked and hoodwinked by the Brahmin Saṅgha. (The discourses with the wise Nāgasena, in *Buddh. Lit. Soc. Rec.*, xlvii., xxxv., xxxvi.)

The old coins of Apollodotus and Menander, with Greek legends, were still in currency in Barygaza (mod. Broach), the great port of Gujarat, about A.D. 70 we are told by the *Periplus maris Erythraei*, 48. We possess many of these coins, which follow the Indian standard and are artistically degenerate. Several, in the Graeco-Bactrian and Graeco-Indian coins, with bilingual legends (Greek and Kharoshthi, see BACTRIA).

The Milanda has been edited in Pali by V. Trencker, and translated into German by Burt, with an introduction which the historical and critical points made in this article are discussed in detail. There is space here to mention only one further fact. M. Sylvain Lévy, working in collaboration with M. Specht, has shown that there are two not-three, Chinese works written between the 5th and 7th centuries, on the Questions of Milinda. They purport to be translations of Indian works. They are not, however, translations of the Pali text. They give, with alterations and additions, much of the material of the earlier part of the Pali work; and are probably derived from a recession that may be older than the Pali.

AUTHORITIES.—V. Trencker, Milinda-pañha (London, 1880); Rhys Davids, Questions of King Milinda (2 vols., Oxford, 1890-1894); R. Garbe, Beitragz zur indischen Kulturgeschichte (Berlin, 1903); ch. 3, Der Milinda-pañha; Milanda Prashaya, in Sinhalese, (Colombo, 1906, 2 vols., 5th ed., 1882); see also W. Nitsche, Der Rhetor. MENANDER, of Laodice on the Lyceus, Greek rhetorician and commentator. Two incomplete treatises on epideictic (or show) speeches have been preserved of his work. It is generally considered that they cannot be by the same author. Bursian attributes the first to Menander, whom he placed in the 4th century, and the second to an anonymous rhetorician of Alexandria Troas, who possibly lived in the time of Diocletian. Others, from the superscription of the Paris MS, assign the first to Genethlius of Petrae in Palestine. In view of the general tradition of antiquity, that both treatises were the work of Menander, it is possible that the author of the second was not identical with the Menander mentioned by Suidas, since the name is a frequent occurrence in later Greek literature. The first treatise, entitled Πρασίνη τῶν ενθέδων, discusses the different kinds of epideictic speeches; the second, Περὶ ενθέδων, has special titles for each chapter.

Text in L. Spengel's Rhetares graeci, iii. 339-446, and in C. Bursian's "Der Rhetor Menandros und seine Schriften in C. Wendel, der hayer. Akad. der Wissenschaften, xvi. (1882); see also W. Nitsche, Der Rhetor. M. und d. Schollen zu Demosthenes; J. E. Sandlin, Hist. of Classical Scholarship (1900), 338; W. Christ, Gesch. der griechischen Literatur (1898), § 559.

MENANDER PROTECTOR (Ποίοταρκος, i.e. one of the imperial bodyguards), Byzantine historian, was born in Constantinople in the middle of the 6th century A.D. The little that is known of his life is contained in the account of himself quoted by Suidas. He at first took up the study of law, but abandoned it for a life of pleasure. When his fortunes were low, the patronage accorded to literature by the emperor Maurice (582) encouraged him to try writing history. He took as his model Agathias (q.v.), who like him had been a jurist, and his history begins at the point where Agathias leaves off. It embraces the period from the arrival of the Cotriguri Hunni in Thrace during the reign of Justinian in 538 down to the death of the emperor Tiberius in 532. Considerable fragments of the work are preserved in the excerpts of Constantine Porphyrogennitus and in Suidas. Although the style is sometimes bombastic, he is considered trustworthy and is one of the most valuable authorities for the historical matters. He was an eye-witness of some of the events he describes. Like Agathias, he wrote epigrams, one of which, on a Perian magus, who became a convert to Christianity and died the death of a martyr, is preserved in the Greek anthology (Anth. Pal. ii. 101).

The fragments will be found in C. W. Müller, Frag. hist. graec. liv. 200, 245; and in W. Doty, Patrologia graeca, xiil., and L. Denier, Geschichte der byzantinischen Literatur (1897).

MENANGKABOS, the most civilized of all the true Malays of Sumatra, inhabiting the mountains above Padang. Their district is regarded as the cradle of the Malay race, and thence began, about 1160, those migrations which ended in the true Malay Empire. The dominant race throughout the peninsula and the Malay Archipelago. The Menangkabos are the original conquerors of the island, and the real form of the word is Menang-Karbau ("victory of the buffalo"), in reference to a local legend of a fight between a Sumatran and Javanese buffalo, ending in victory for the former. Though converts to Islam, the ancient confederate village communities and the matriarchal system still exist. The people are divided into clans, the chiefs together forming the district council. Early in the 19th century a religious sect was founded among the Menangkabos, known as "Padris" from its zealous proselytism, or "Orang puoi" (white men) from the converts being dressed in white. The tendency was towards asceticism, and the chief tenet being the prohibition of opium, the use of which was made a capital offence. The sect brought a large portion of the interior of Sumatra under its rule, but the neighbouring tribes asked the Dutch to protect them, and this led to the Netherlands government acquiring the Menangkabos territory.

MÉNANT, JOACHIM (1820-1899), French magistrate and orientalist, was born at Cherbourg on the 16th of April 1820. He was educated for the law, and became vice-president of the civil tribunal of Rouen in 1878, and a member of the cour d'appel three years later. But he became best known by his studies on the cuneiform inscriptions. Among his works on the subject of Assyriology are: Recueil d'alphabets des tercires cuniformes (1860); Exposé des éléments de la grammaire assyrienne (1868); Le Syllabaire assyrien (2 vols., 1869-1873); Les Langues perdues de la Perse et de l'Assyrie (2 vols., 1885-1886); Les Pierres gravées de la Haute-Asie (2 vols., 1885-1886). He also collaborated with Julius Oppert. He was admitted to the Academy of Inscriptions in 1885, and died in Paris on the 30th of August 1890.

His daughter DELPHINE (5. 1850) received a prize from the Académie for her Les Pierres gravées des communautes soro-astroïsmes de l'Inde (1858), and was sent in 1900-1901 to British India on a scientific mission, of which she published a report in 1903.

MÉNARD, LOUIS NICOLAS (1822-1901), French man of letters, was born in Paris on the 10th of October 1822. His versatile genius occupied itself in turn with chemistry, poetry, painting and history. In 1843 he published, under the pseudonym of L. de Senneville, a translation of Prométhée délivré. Turning to chemistry, he discovered collodion in 1846, but its value was not recognized at the time; and its application later to surgery and photography brought him no advantage. Louis Ménard was a socialist, always in advance of the reform movements of his time. After 1848 he was condemned to imprisonment for his Prologue d'une révolution. He escaped to London, returning to Paris only in 1852. Until 1860 he occupied himself with classical studies, the fruits of which are to be seen in his Polèmes (1853), Polythéisme hélénique (1863), and two academic theses, De sacra poesi graecorum et La Morale avant les philosophes (1866). The next ten years Ménard spent chiefly among the Barbizon artists, and he exhibited several pictures. He published in London at this period of the Connie Ménard, a novel, with his pen. In 1887 he became professor at the École des Arts décoratifs, and in 1895 professor of universal history at the Hôtel de Ville in Paris. His Réveries d'un poète mystique (1876), which contained sonnets, philosophical dialogues and some stories, was followed in 1896 by Poèmes et rêveries d'un poète mystique. Ménard died in Paris on the 12th of February 1901.

His works include: Histoire des anciens peuples de l'Orient (1884); Histoire des Israélites d'après l'exégèse biblique (1885), and Histoire des Phéniciens (1884-1886). Ménard published an apparatus to Appian in the opening chapter of Maurice Barrès's Voyage de Sparte.

MENASHA (an Indian word meaning "thorn" or "of island"), a city of Winnebago county, Wisconsin, U.S.A., 88 m. N. of Milwaukee, and 14 m. N. of Oshkosh, attractively situated at the N. extremity of Lake Winnebago at its outlet into the Fox river. Pop. (1890), 4581; (1900), 5589 (1533 foreign-born); (1905, state census), 5960; (1910), 6081. Menasha is served by the Minneapolis, St Paul & Sault Ste Marie, the Chicago, Milwaukee & St Paul, and the Chicago & North-Western railways, and by an inter-urban electric railway system. Several bridges across the Fox River connect Menasha with Neenah, which it really is. It is attractively situated on the confluence of two rivers, at the mouth of the river and divided about equally between the cities, is a picturesque and popular summer resort.
MENASSEH BEN ISRAEL—MENCIUS

Menasseh had good water power and among its manufactures are paper and sulphite pulp, lumber, wooden-ware and cooperation products, woolen and knit goods, leather, boats and bricks. The first white man to visit the site of Menasseh was probably Jean Nicolet, who seems to have come in the winter of 1634-1635 and to have found here villages of Fox and Winnebago Indians. Subsequently there were French and English trading posts here. The city was settled permanently in 1848, and was chartered in 1874.

MENASSEH BEN ISRAEL (c.1604-1657), Jewish leader, was born in Lisbon about 1604, and was brought up in Amsterdam. His family had suffered under the Inquisition, but found an asylum first in La Rochelle and later in Holland. Here Menasseh rose to eminence not only as a rabbi and an author, but also as a printer. He established the first Hebrew press in Holland. One of his earliest works El Conciileior won immediate reputation. It was an attempt at reconciliation between apparent discrepancies in various parts of the Old Testament. Among his correspondents were Vossius, Grotius and Huet. In 1638 he decided to settle in Brazil, as he still found it difficult to provide in Amsterdam for his wife and family, but this step was rendered unnecessary by his appointment to direct a college founded by the Pereiras.

In 1644 Menasseh met Antonio de Montesinos, who persuaded him that the North-American Indians were the descendants of the lost ten tribes of Israel. This supposed discovery gave a new impulse to Menasseh's Messianic hopes. But he was convinced that the Messianic age needed as its certain precursor the settlement of Jews in all parts of the known world. Filled with this idea, he turned his attention to England, whence the Jews had been expelled since 1290. He found much Christian support in England. During the Commonwealth the question of the readmission of the Jews was often mooted under the growing desire for religious liberty. Besides this, Messianic and other mystic hopes were current in England. In 1650 appeared an English version of the Hope of Israel, a tract which deeply impressed public opinion. Cromwell had been moved to sympathy with the Jewish cause partly by his tolerant leanings, but chiefly because he foresaw the importance for English commerce of the presence of the Jewish merchant princes, some of whom had already found their way to London. At this juncture Jews received full rights in the colony of Surinam, which had been English since 1650. In 1655 Menasseh arrived in London. It was during his absence that the Amsterdam Rabbis communicated Spinoza, a catastrophe which would probably have been avoided had Menasseh—Spinoza's teacher—been on the spot. One of his first acts on reaching London was the issue of his Humble Address to the Lord Protector, but its effect was nullified by the issue of Prynne's able but unfortunate Short Remonstrance. Cromwell summoned the Whitchell Conference in December of the same year. To this conference were summoned some of the most notable statesmen, lawyers and theologians of the day. The chief practical result was the declaration of Judges Glynne and Steele that "there was no law which forbade the Jews' return to England." Though, therefore, nothing was done to regularize the position of the Jews, the door was opened to their gradual return. Hence John Evelyn was able to enter in his Diary under the date Dec. 14, 1655, "Now were the Jews admitted." But the attack on the Jews by Prynne and others could not go unanswered. Menasseh replied in the finest of his works, Vindicatio judaeorum (1656). "The best tribute to its value is afforded by the fact that it has since been frequently reprinted in all parts of Europe when the calumnies it denounced have been reviled" (L. Wolf). Among those who used in this way Menasseh's Vindicatio was Moses Mendelssohn (q. v.). Soon after Menasseh left London Cromwell granted him a pension, but he died before he could enjoy it. Death overtook him at Middelburg, when he was conveying the body of his son Samuel home for burial.

Menasseh ben Israel was the author of many works, but his English tracts remain the only ones of importance. His De termino vitae was translated into English by Pococke, and his Conciliator by G. H. Lindo. Among his other works were a ritual compendium Tesoro dos dinim, and a treatise on Hebrew on immortality (Nishmoth hayim). He was a friend of Rembrandt, who painted his portrait and engraved four etchings to illustrate his Pedro gloriosa. These are preserved in the British Museum.

MENCIUS, the latinized form of Mäng-tsze, "Mr. Mäng," or "Mäng the philosopher," a Chinese moral teacher whose name stands second only to that of Confucius. His statue or spirit-tablet (as the case may be) has occupied, in the temples of the sage, since our 11th century, a place among the four assessors, and since A.D. 1530 his title has been "the philosopher Mäng, sage of the second degree."

The Mängus or Mäng-suns had been in the time of Confucius one of the three great clans of Lû (all descended from the marquis Hwan, 711-604 B.C.), which he had endeavoured to curb. Their power had subsequently been broken, and the branch to which Mencius belonged had settled in Tàsu, a small adjacent principality, the name of which remains in Tàsu hsien, a district of Yenchâu Shan-tung. A magnificent temple to Mencius is the chief attraction of the district city. The large marble statue of Mencius in the courtyard shows much artistic skill, and gives the impression of a man strong in body and mind, thoughtful and fearless. His lineal representative lives in the city, and thousands of Mängs are to be found in the neighbourhood.

Mencius, who died in the year 289 B.C., had lived to a great age—some say to his eighty-fourth year, placing his birth in 372 B.C., and others to his ninety-seventh, placing it in 385. All that we are told of his father is that he died in the third year of the child, who was thus left to the care of his mother. Her virtues and dealings with her son were celebrated by a great writer in the 1st century before our era, and for two thousand years she has been the model mother of China.

Mencius is more than forty years old when he comes before us as a public character. He must have spent much time in study, investigating questions as to the fundamental principles of morals and society, and brooding over the condition of the country. The history, the poetry, the institutions and the great men of the past had received his attention. He intimates that he had been in communication with men who had been disciples of Confucius. That sage had become to him the chief of mortal men, the object of his unstringing admiration; and in the doctrines which he had founded he recognized the truth in want of an appreciation of which the bonds of order all round him were being relaxed, and the kingdom hastening to anarchy.

When he first comes forth from Tàsu, he is accompanied by several eminent disciples. He had probably imitated Confucius in becoming the master of a school, and encouraging the resort to it of inquiring minds that he might resolve their doubts and unfold to them the right methods of government. One of his sayings is that it would be a greater delight to the superior man to get the youth of brightest promise around him and to teach and train them than to enjoy the revenues of the kingdom. His intercourse with his followers was not so intimate as that of Confucius had been with the members of his selected circle; and, while he maintained his dignity among them, he was not able to secure from them the same homage and reverent admiration.

More than a century had elapsed since the death of Confucius, and during that period the feudal kingdom of Châu had been showing more and more of the signs of dissolution, and portentous errors that threatened to upset all social order were widely disseminated. The sentiment of loyalty to the dynasty had disappeared. Several of the marquesses and other feudal princes of earlier times had usurped the title of king. The smaller sires had been absorbed by the larger ones, or reduced to helpless dependence on them. Tsin, after greatly extending its territory,
had broken up into three powerful kingdoms, each about as large as England. Mencius found the nation nominally one, and with the traditions of two thousand years affirming its essential unity, but actually divided into seven monarchies, each seeking to subdue the others under itself. The consequences were constant warfare and chronic misery.

In Confucius's time we meet with recluse who had withdrawn in disgust from the world and its turmoil; but these had now given place to the more worldly reformers, who gathered about them, and the services provided with arts of war or schemes of policy which they recommended to the contending chiefs, ever ready to change their allegiance as they were moved by whim or interest. Mencius was once asked about two of them, "Are they not really great men? Let them be angry, and all the princes are afraid. Let them live quietly, and the flames of trouble are everywhere extinguished." He looked on them as little men, and delighted to proclaim his idea of the great man in such language as the following:

"To dwell in love, the wide house of the world, to stand in propriety, the correct seat of the old, and to walk in simplicity, the great path of the world; when he obtains his desire for office, to practise his principles for the good of the people, and when that desire is disappointed, to practise them alone; to be absolute in power and make discords cease; to be absolute in poverty and mean condition to make swerve from the right, and of power and force to make bend—these characteristics constitute the great man."

Most vivid are the pictures which Mencius gives of the condition of the people in consequence of the wars of the states. The royal ordinances were violated; the multitudes were overborne; the punishment of the law was not administered with an iron hand; the people, thrown away like water. It is not wonderful that, when the foundations of government were thus overthrown, speculations should have arisen that threatened to overthrow what he considered to be the foundations of truth and all social order. "A shrill-tongued barbarian from the south," as Mencius called him, proclaimed the dissolution of ranks, and advocated a return to primitive simplicity. He and his followers maintained that learning was quackery, and statesmanship craft and oppression, that prince and peasant should be on the same level, and every man do everything for himself. Another, called Yang-chú, denied the difference between virtue and vice; glory and shame. It was the same with all at death. The conclusion therefore was: "Let us eat and drink; let us gratify the ears and eyes, get servants and maidsens, beauty, music, wine; when the day is insufficient, carry it on through the night. Each one for himself." Against this heresiarch, of a very different stamp, Mencius felt no less indignation. This was Mo Ti, who found the source of all the evils of the time and of all time in the want of mutual love. He taught, therefore, that men should love others as themselves; princes, the states of other princes as much as their own; children, the parents of others as much as their own. Mo, in his gropings, had got hold of a noble principle, but he did not apprehend it distinctly nor set it forth with discrimination. To our philosopher the doctrine appeared contrary to the Confucian orthodoxy about the five relations of society; and he attacked it without mercy and with an equal confusion of thought. "Yang's principle," he said, "is 'each one for himself,' which does not acknowledge the claims of the sovereign. Mo's is 'to love all equally,' which does not acknowledge the peculiar affection due to a father. But to acknowledge neither king nor father is to be in the state of a beast. The way of benevolence and righteousness is stopped up."

On this ocean of lawlessness, wickedness, heresies and miseries Mencius looked out from the quiet of his school, and his spirit was stirred to attempt the rescue of the people from misrule and error. "If Heaven," he said, "wishes that the kingdom should enjoy tranquillity and good order, who is there besides me to bring it about?" He formed his plan, and proceeded to put it in execution. He would go about among the different kings till he should find one among them who would follow his counsels and commit to him the entire administration of his government. That obtained, he did not doubt that in a few years there would be a kingdom so strong and so good that all rulers would acknowledge its superiority, and the people hasten from all quarters to crown its sovereign as monarch of the whole of China. This plan was much the same as that of Confucius had been; but, with the bolder character that belonged to him, Mencius took in one respect a position from which the master would have shrank. The former was always loyal to Ch'âu, and thought he could save the country by a right and just action; the latter saw the day of Ch'âu was past, and the time was come for a revolution. Mencius's view was the more correct, but he was not wiser than the sage in forecasting for the future. They could think only of a reformed dynasty or of a changed dynasty, ruling according to the model principles of a feudal constitution, which they described in glowing language. They desired a repetition of the golden age in the remote past; but soon after Mencius disappeared from the stage of life there came the sovereign of Ch'in, and solved the question with fire and sword, introducing the more to the military genius of their founders than to the wisdom and organizing ability of the learned men, the statesmen, who were their bosom friends and trusted counsellors. Why should not he become to one of the princes of his day what I Yin had been to Thang, and Thâi-kung Wang to King Wên, and the duke of Chê to Wô and Ch'âng? But, though Mencius might be the equal of any of those worthies, he knew of no prince like Thang and the others, of noble aim and soul, who would adopt his lessons. In his caginess he overlooked this condition of success for his enterprise. He might meet with such a ruler as looked for advancement, and was a bad one, and make him the condutor that he required. On the strength of these peradventures, and attended by several of his disciples, Mencius went for more than twenty years from one court to another, always baffled, and always ready to try again. He was received with great respect by kings and princes. He would not enter into the service of any of them, but he occasionally accepted honorary offices of distinction; and he did not scruple to receive large gifts which enabled him to live and move about as a man of wealth. In delivering his message he was as fearless and outspoken as John Knox. He lectured great men, and ridiculed the futilitudes of the day; the wiser kings, and pointed out the path to universal sway; but it was all in vain. He could not stir any one to honourable action. He confronted herey with strong arguments and exposed it with withering sarcasm; but he could work no deliverance in the earth. The last court at which we find him was that of Lâu, probably in 310 B.C. The marquis of that state had given office to Yo-châng, one of Mencius's disciples, and he hoped that this might be the means of a favourable hearing for himself. So it had nearly happened. On the suggestion of Yo-châng the marquis had ordered his carriage to be yoked, and was about to step into it and proceed to bring Mencius to his palace, when an unworthy
favourite stepped in and diverted him from his purpose. The disciple told his master what had occurred, reproaching the favour for his ill-timed intervention; Mencius, however, said to him, "A man's advancement or the arresting of it may seem to be effected by others, but is really beyond their power. My not finding in the marquis of Lu a man who would confide in is no evidence in praise or blame from Heaven."

Mencius accepted this incident as a final intimation to him of the will of Heaven. He had striven long against adverse circumstances, but now he bowed in submission. He withdrew from courts and the public arena. According to tradition he passed the last twenty years of his life in the society of his disciples, discoursing to them, and giving the finishing touches to the record of his conversations and opinions, which were afterwards edited by them, and constitute his works. Mencius was not so oracular, nor so self-contained, as Confucius; but his teachings have a vivacity and sparkle all their own.

Mencius held with Confucius—and it was a doctrine which had descended to them both from the remotest antiquity—that royal government is an institution of God. An ancient sovereign had said that "Heaven, having produced the people, appointed for them rulers, and appointed for them teachers, who should be assisting and directing them in the affairs of the state; and the manifest incompetency of all the rulers of his time to ask how it could be known on what individual the appointment of Heaven had been made, that the prince should be ascertained only from his personal character and his conduct of affairs. The people must find out the will of Heaven as to who should be their ruler for themselves. There was another old saying which the people held for true, "Heaven is bare to the people as the people hear." He taught accordingly that, while government is from God, the governors are from the people;—sae popularis esse Dei. No claim then of a divine right should be allowed to a sovereign if he were not exercising a rule for the good of the people. The "people" are the most important element in a nation; the altars to the spirits of the land and grain are the second; the sovereign is the lightest. Mencius was not afraid to follow this utterance to its consequences. The monarch whose rule is injurious to the people, and who is deaf to remonstrance and counsel, should be dethroned. In such a case "killing is no murder." But who is to be the judge of an unjust government? Mencius had three answers to this difficult question. First, he would have the members of the royal house perform the task. Let them disown their unworthy head, and appoint some better individual of their number in his room. If they could not or would not do this, he thought, secondly, that any high minister, though not allied to the royal house, might take summary measures with the aid of the people; and that he should then be acclaimed with public acclamation. His third and grand device was what he called "the minister of Heaven." When the sovereign had become a pest instead of a blessing, he believed that Heaven would raise up some one to drudge the house of a king which should himself take the reigns in his original subordinate position as to draw all eyes and hearts to himself. Let him then raise the standard not of rebellion against the king, but of justice, and the people would follow him and be raised to the highest dignity. Mencius hoped to find one among the rulers of his day who might be made into such a minister, and he counselled one and another to adopt measures with that object. It was in fact counselling rebellion, but he held that the house of Ch'au had forfeited its title to the throne.

A good government according to his ideal must be animated by a spirit of benevolence, and ever pursue a policy of righteousness. Its aims must be, first, to make the people well off, and next, to educate them. No one was fit to occupy the throne who could be happy while any of the people were miserable, who delighted in the goods of others while his own were wanting, and who did not in a measure share with him. Game laws received his emphatic condemnation. Taxes should be light, and all the regulations for agriculture and commerce of a character to promote and encourage them. The rules which he suggested to regulate the slave trade and commerce had reference to the existing condition of his country, but they are susceptible of wide application. They carry in them schemes of Drainage and irrigation for land, and of free trade for commerce. But it must be he contented, that a sufficient and certain livelihood be secured for all the people. Without this their minds cannot be at rest, and they must continue to proceed to every form of wild licentiousness. They would break the law, and their indulgence in vice would not be restrained by the fear of punishment—punish them whom his neglect of his own duties had plunged into poverty, of which crime was the consequence. He said, "The people have the right to starve, but no right to steal."

Supposing the people to be made well off, Mencius taught that education should be provided for them all. He gave the marquis of Lu a programme of four kinds of educational institutions, which he wished him to establish in his state—in the villages and the towns, for the poor as well as the rich, so that none might be ignorant of his duties in the various relations of society. But he would not have the government give them free schools. "If he would do good work, he had not much faith in the power of education to make them virtuous. Give him, however, a government fulfilling the conditions that he laid down, and he was confident there would be no need of them, as the people, all living together in peace, would have nothing to prevent the realization of such a government. Any ruler might become, if he would, "the minister of Heaven," who was his ideal, and the people would come and call on him for help, and would see the shade of their mulberry trees, and hail the ruler "king by the grace of Heaven."

Opinions were much divided among his contemporaries on the subject of human nature. Some held that the nature of man is evil, or not altogether good, and that Heaven did nothing to do evil. Others held that the nature of some men is good, and of others bad; thus it is that the best of men sometimes have had, and are the worst of men good sons. He was also taught that the nature of man is evil, and whatever good appears in it is the result of cultivation. In opposition to all these views Mencius contended that the nature of man is good. "Water," he said, "will flow indifferently to the east or west; but will it flow indifferently up or down? The tendency of man's nature to goodness is like the tendency of water to flow downwards. By striking water, let us make it ascend, and leading it you may make it go up a hill. But such movements are not according to the nature of water; it is the force applied which causes them. When men do what is not good, or act against the principles of right, it is the force of personal circumstances, but equally felicitous illustration he replied to his different opponents. Sometimes he may seem to express himself too strongly, but an attentive study of his writings shows that he is speaking more of the acting on the nature of man by personal circumstances, than by any ascertain, by an analysis of it, that it was intended to be, and not as it has been made to become.

The two constituents of human nature, dwelling especially on the principles of benevolence, righteousness, propriety, and wisdom or knowledge, the last including the judgment of conscience. These, he said, are not infused into us from without. Men have these four principles just as they have their four limbs. But man has also instincts and appetites which seek their own gratification without reference to righteousness or any other control. He met this difficulty by contending that human nature is not only reasonable, but reasonable amongst reasonable beings. He held that human beings are designed to rule the lower. "Some constitutients of it are noble and some ignoble, some great and some small. The great must not be injured for the small, nor the noble for the ignoble."

One of his most vigorous vindications of his doctrine is the following: "For the mouth to desire favours, the eyes colours, the car sounds, and the four limbs ease and rest belong to man's nature, and are the result of the development of his animal affections. An animal might be found, indeed, who should live like a philosopher, and who should have no desire for these things. But such a man is not known; and he would be discriminated by the addition of some term, as the term, for instance, "as it is" may be added to the name of Heaven."

When he proceeded from his ideal of human nature to account for the actual phenomena of conduct, he was necessarily less successful. There is nothing good, he said, "that a man cannot do; he only does not do it." But why does he not do it? Against the stubborn fact Mencius beats his wings and shatters his weapons with the wind. He mentions a few ancient worthies who, he conceived, had always been, or who had become, perfectly virtuous. Above them all he extols Confucius, taking no notice of that sage's confession that he had not attained to conformity to his own rule. An exception was made to him. No man ever lived so much, and no man could be acknowledged about himself ever came from Mencius. Therein he was inferior to his predecessor; he had a subtler faculty of thought, and a much more vivid imagination; but he did not know how to hold his guileless speculations together.

A few passages illustrative of his style and general teachings will complete all that can be said of him here. His thoughts, indeed, were seldom condensed like those of "the master" into aphorisms, and should be read in their connexion; but we have from him many words of wisdom that have been as good to millions for more than two thousand years. For instance—

"The great man is he who does not lose his child-heart."
MENDE—MENDELEISM

"The sense of shame is to a man of great importance. When one is ashamed of having been without shame, he will afterwards not have occasion for shame." 

"If you nourish the heart, there is nothing better than to keep the desires few. Here is a man whose desires are few; in some things he may not be able to keep his heart, but they will be few. Here is a man whose desires are many; in some things he may be able to keep his heart, but the things will be few.

"Beneficence is the distinguishing characteristic of man. As embodied in his conduct, it may be called the path of duty."

"There is an organization for everything; and a man should receive submissively what may be correctly ascribed thereto. He who has the correct idea of what Heaven's organization is will not stand beneath a tooting wall. Death sustained in the discharge of one's duties may be, but that, "Death under handicaps and fetters cannot be correctly ascribed."

"When one by force subdues men, they do not submit to him in heart. When he subdues them by virtue, in their hearts' core shall the God of grace and mercy subdue them."

Two translations of the works of Mencius are within the reach of European readers: that by Stanislaus Julien, in Latin (Paris, 1824-1829); and that forming the second volume of Legge's Chinese Classics (Hong-Kong, 1862). The latter has been published at London (1875) without the Chinese text. See also E. Faber, The Mind of Mencius, or Political Economy founded on Moral Philosophy, translated from the German by A. B. Hutchinson (London, 1882). (J. L.)

MENDE, a town of south-eastern France, capital of the department of Lotzère, 59 m. N.N.E. of Millau by rail. Pop. (1906), town 5246; commune 7007. Mende is picturesquely situated on the left bank of the Lot, and at the foot of the Mimel cliff, which rises 1000 ft. above the town, and terminates the Causse de Mende. The town is the seat of a bishopric. Its cathedral, St. Peter was founded in the 11th century by Pope Urban V. to serve the district, but the two towers, respectively 380 and 210 ft. high, were added by Bishop François de Rovère in the early part of the 16th century. Partly destroyed during the devastation of the town by the Protestants in 1579 and 1580, it was rebuilt in the 17th century, and in 1754 a statue of Urban V. was erected in front of it. A Renaissance tower of the ancient citadel now serves as the belfry of the church of the Penitents, and a 14th-century bridge crosses the Lot. The town is a convenient centre for visitors to the gorges of the Tarn. It is the seat of a prefect and a court of assize, and has a tribunal of instance and a chamber of commerce. The chief industry is the manufacture of serge and shawls, known as Mende stuffs, exported to Spain, Italy and Germany.

Mende (Mimate) grew up around the hermitage, partly excavated in the side of the Mimel cliff, to which St. Prival, bishop of Javel, retreated after the destruction of that town, and where he was subsequently slain by the Vandals, who had pursued him thither, about 408. In the 14th century the new town became the civil, as it had previously been the ecclesiastical, capital of the Gave and district.

MENDELEÉFF, DMITRI IVANOVICH (1834—1907), Russian chemist, the youngest of a family of seventeen, was born at Tobolsk, Siberia, on the 7th of February (n.s.) 1834. After attending the gymnasium of his native place, he went to study natural science at St. Petersburg, where he graduated in chemistry in 1856, subsequently becoming privatdocent. In 1860 he went to Heidelberg, where he started a laboratory of his own, but returning to St. Petersburg in 1861, he became professor of chemistry in the technological institute there in 1863, and three years later succeeded to the same chair in the university, which he resigned the professorship, and in 1893 he was appointed director of the Institute of Weights and Measures, a post which he occupied till his death.

Mendelev's original work covered a wide range, from questions in applied chemistry to the most general problems of chemical and physical theory. His name is best known for his work on the Periodic Law. Various chemists had traced numerical sequences among the atomic weights of some of the elements and noted connections between them and the properties of the different substances; but it was left to him to give a full expression to the generalization, and to treat it not merely as a system of classifying the elements according to certain observed facts, but as a "law of nature" which could be relied upon to predict new facts and to disclose errors in what were supposed to be old facts. Thus in 1871 he was led by certain gaps in his tables to assert the existence of three new elements so far unknown to the chemist, and to assign them definite properties. These three he called eka boron, ekaaluminium, and ekasilicon; and his prophecy was completely vindicated within fifteen years by the discovery of gallium in 1871, scandium in 1879, and germanium in 1886. Again, in several cases he ventured to question the correctness of the "accepted atomic weights," on the ground that they did not correspond with the Periodic Law, and here also he was justified by subsequent investigation. In 1902, in an "attempt at a chemical conception of life," the other, he put forward the hypothesis that there are in existence two classes of smaller atomic weight than hydrogen, and that the lighter of these is a chemically inert, exceedingly mobile, all-penetrating and all-pervading gas, which constitutes the ether. Mendeleev also devoted much study to the nature of such "indefinite" compounds as solutions, which he looked upon as homogeneous liquid systems of unstable dissociating compounds of the solvent with the substance dissolved, holding the opinion that they are merely an instance of ordinary definite compound formation according to Dalton's laws. In another department of physical chemistry he investigated the expansion of liquids with heat, and devised a formula for its expression similar to Gay-Lussac's law of the uniformity of the expansion of gases, while so far back as 1861 he anticipated T. Andrews's conception of the critical temperature of gases by defining the absolute boiling-point of a substance as the temperature at which cohesion and heat of vaporization become equal to zero and the liquid changes to vapour, irrespective of the pressure and volume. Mendeleev wrote largely on chemical topics, his most widely known book probably being The Principles of Chemistry, which was written in 1866—1870, and has gone through many subsequent editions in various languages. For his work on the Periodic Law he was awarded in 1882, at the same time as L. Meyer, the Davy medal of the Royal Society, and in 1905 he received his Copley medal. He died at St. Petersburg on the 2nd of February 1907.

MENDELISM. To define what some biologists call Mendelism briefly is not possible. Within recent years there has come to biologists a new idea of the nature of living things, a new conception of their potentialities and of their limitations; and for this we are primarily indebted to the work of Gregor Mendel. Peasant boy, monk, and abbot of Brünn, this remarkable man at one time interested himself in the workings of heredity, and the experiments devised by him and carried out in his cloister garden are to-day accepted by him and the rest of humanity. Mendel's ideas have steadily gained ground, and, as the already strong body of evidence in their favour grows, they must come to exert upon biological conceptions an influence not less than that associated with the name of Darwin.

Dominant and Recessive.—Mendel chose the common pea (Pisum sativum) as a subject for experiment, and investigated the effects of crossing different varieties. In his method he differed from previous investigators in concentrating his attention on the mode of inheritance of a single pair of alternative characters at a time. Thus on crossing a tall with a dwarf and paying attention to this pair of characters alone, he found that the hybrids (or F1 generation) were all tall and that no intermediates appeared. Accordingly he termed the tall character dominant and the dwarf character recessive. On allowing these hybrids to fertilize themselves in the ordinary
MENDELISM

way he obtained a further generation which on the average was composed of three tall to one dwarf. Subsequent experiment showed that the dwarfs always bred true, as did also one out of every three tall; the two remaining tails behaved as the original hybrids in giving three tails to one dwarf. Having regard to the characters, tallness and dwarfishness, three and only three kinds of peas exist, viz. dwarfs which breed true, tails which breed true, and tails which give a finer proportion of tails and dwarfs. The relation between these three forms may be briefly summarized in the subjoined scheme, in which pure tall and dwarf are represented by T and D respectively, while [T] denotes the tails which do not breed true. Experiments were also made with several other pairs of characters, and the same mode of inheritance was shown to hold good throughout.

Unit-Characters.—As Mendel clearly perceived, these definite results lead inevitably to a precise conception of the constitution of the reproductive cells, or gametes; and to appreciate fully the change wrought in our point of view necessitates a brief digression into the essential features of the reproductive process. A sexual process (see Sex) is almost universal among animals and plants, and consists essentially of the union of two gametes, of which one is produced by either parent. Every gamete contains small definite bodies known as chromosomes, and the number of these is, with few known exceptions, constant for the gametes of a given species. On the fusion of two gametes the resulting cell or zygote has therefore a double structure, for it contains an equal number of chromosomes brought in by the paternal and by the maternal gamete—in the case of a plant by the pollen grain as well as by the ovule. By a process of repeated division the zygote gives rise to a plant (or an animal) whose cells apparently retain the double structure throughout. Certain of the cells of such a zygote become the germ cells and are set apart, as it were, for the formation of gametes. Histology has shown that when this occurs the cells lose the double structure which they had hitherto possessed, and that as the result of a process known as the reduction division gametes are formed in which the number of chromosomes is one half of that which characterizes the cells of the zygote. It is generally acknowledged that the characters play an important part in the hereditary process, and it is possible that the divisions which they undergo in gametogenesis are connected with the observed inheritance of characters. We shall refer later to the few observations which seem to connect the two sets of phenomena.

Our conception of what occurs when a cross is made between two individuals may be illustrated by the diagram which forms fig. 2. Zygotes are here represented by squares and gametes by circles. The dominant and recessive characters are indicated by small plain and black rectangles. Each zygote must contain two and each gamete but one of these unit-characters. Zygotes such as the original parents which breed true to a given character are said to be homozygous for that character, and from their nature such homozygotes must produce identical gametes. Consequently when a cross is made only one kind of zygote can be formed, viz. that containing both the dominant and recessive unit-characters. When the germ-cells of such a heterozygote split to form gametes, these, as indicated in fig. 2, will be of two sorts containing the dominant and recessive characters respectively, and will be produced in equal numbers. If we are dealing with a hermaphrodite plant such as the pea the ovules will consist of one half bearing only the dominant character and one half bearing only the recessive character; and this will be true also of the pollen grains. Consequently each ovule will be an equal chance of being fertilized by a dominant or by a recessive pollen grain, and the dominant ovules must therefore give rise to equal numbers of dominant homozygous and of heterozygous plants. Similarly the recessive ovules must give rise to equal numbers of recessive homozygotes and of heterozygotes. Hence of the total offspring of such a plant one quarter will be pure dominants, one quarter recessives, and one half heterozygotes as indicated in fig. 2. Where one character is completely dominant over the other, heterozygotes will be indistinguishable in appearance from the homozygous dominant, and the F2 generation will be completely uniform, each F1 plant giving rise to plants all of which exhibit the same character, whether dominant or recessive.

Illustrations.—Mendelian inheritance in its simplest form, i.e. for a single pair of characters, has already been shown to occur in many species of animals and plants, and for many very diverse characters. In some cases complete dominance of one of the pair of unit-characters occurs; in others the form of heterozygote is more or less intermediate. Fresh cases are continually being recorded and the following short list can but serve to give some idea of the variety of characters in which Mendelian inheritance has been demonstrated.

A. Dominance nearly or quite complete. (The dominant character is given first.)
- Tall and dwarf habit (pea, sweet pea).
- Round and wrinkled seed (pea).
- Long and round pollen (sweet pea).
- Starch and sugar endosperm (maize).
- Ears and absence of hairs (stocks, Lycopsis).
- Beardless and bearded condition (wheat).
- Prickliness and smoothness of fruits (Datura).
- Palm and fern leaf (Primula).
- Purple and red flowers (sweet pea, stocks, &c.).
- Fertility and sterility of anthers (sweet pea).
- Susceptibility and immunity to rust (wheat).
- Rose comb and single comb (fowls).
- Black and white plumage (geese, bantams).
- Grey and black coat colour (rabbits, mice).
- Bay and chestnut coat colour (horses).
- Pigmentation and albinism (rabbits, rats, mice).
- Polled and horned condition (cattle).
- Short and long "Angora" coat (rabbits).
- Normal and woolly coat (mice).
- Deformed hand with two phalanges in digits and normal hand (man).
B. Absence of dominance, the heterozygote being more or less intermediate in form.

Black and white splashed plumage (Andalusian fowls). Lax and dense ears (wheat).

Six rowed and two rowed ears (barley).

**Dominance.**—The meaning of this phenomenon is at present obscure, and we can make no suggestion as to why it should be possible in one case, partial in another, and entirely absent in a third. When found it is as a rule definite and orderly, but there are cases known where irregularity exists. The extra toe characteristic of certain breeds of fowls, such as Dorkin, behaves generally as a dominant character, but in certain cases it has been ascertained that a foal without an extra toe may yet carry the extra toe character. It is possible that in some cases dominance may be conditioned by the presence of other features, and certain crosses in sheep lend colour to the supposition that sex may be such a feature. A cross between the polled Suffolk and the horned Dorset breeds results in horned rams and polled ewes only, though in the F2 generation both sexes appear with and without horns. At present the simplest hypothesis which fits the facts is that horns are dominant in the male and recessive in the female. It is important not to confuse cases of apparent reversal of dominance such as the above with cases in which a given visible character may be the result of two entirely different causes. One white hen may give only colour chicks by a coloured cock, whilst the same cock with another white hen, indistinguishable in appearance from the former, will give only white chickens containing a few dark ticks. There is here no reversal of dominance, but, as has been abundantly proved by experiment, there are two entirely distinct classes of white fowls, of which one is dominant and the other recessive to colour.

**Presence and Absence Hypothesis.**—Whether the phenomenon of dominance occur or not, the unit-characters exist in pairs, of which the members are seemingly interchangeable. In virtue of this behaviour the unit-characters forming such a pair have been termed allelomorphic to one another, and the question arises as to what is the nature of the relation between two allelomorphs. The fact that such cases of heredity as have been fully worked out can all be formulated in terms of allelomorphic pairs is suggestive, and has led to what may be called the "presence and absence" hypothesis. An allelomorphic pair represents the only two possible states of any given character in its relation to the gamete, viz. its presence or its absence. When the unit-character is present the quality for which it stands is manifested in the zygote: when it is absent some other quality previously concealed is able to appear. When the unit-character for yellowness is present in a pea the seeds are yellow, when it is absent the seeds are green. The green character is underlying in all yellow seeds, but can only appear in the absence of the unit-character for yellowness, and greenness is allelomorphic to yellowness because it is the expression of absence of yellowness.

**Dihybridism.**—The instances hitherto considered are all simple cases in which the individuals crossed differ only in one pair of unit-characters. Mendel himself worked out cases in which the parents differed in more than one allelomorphic pair, and he pointed out that the principles involved were capable of indefinite extension. The inheritance of the various allelomorphic pairs is to be regarded as entirely independent. For example, when two individuals AA and aa are crossed the composition of the F1 generation must be Aa + Aa = AA + 2Aa + aa. If we suppose that the two parents differ also in the allelomorphic pair B and b, the composition of the F2 generation for this pair will be BB + Bb + bb. Hence of the zygotes which are homoygous for AA one quarter will carry also BB, one quarter bb, and one half Bb. And similarly for the zygotes which carry Aa or aa. The various combinations possible together with the relative frequencies of their occurrence may be gathered from fig. 3. Of the 16 zygotes there are:

<table>
<thead>
<tr>
<th>contains A and B</th>
<th>contains B but not A</th>
<th>A but not B</th>
<th>neither A nor B</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>3</td>
<td>3</td>
<td>1</td>
</tr>
</tbody>
</table>

In a case of dihybridism the F1 zygote must be heterozygous for the two allelomorphic pairs, i.e. must be of the constitution Aa Bb. It is obvious that such a result may be produced in two ways, either by the union of two gametes, Ab and aB, or of two gametes Ab and ab. In the former case each parent must be homozygous for one dominant and one recessive character; in the latter case one parent must be homozygous for both the dominant and the other for both recessive characters. The results of a cross involving dihybridism may be complicated in several ways by the reaction upon one another of the unit-characters belonging to the separate allelomorphic pairs, and it will be convenient to consider the various possibilities apart.

1. The simplest case is that in which the two allelomorphic pairs affect entirely distinct characters. In the pea tallness is dominant to dwarfishness and yellow seeds are dominant to green. When a yellow tall is crossed with a green dwarf the F1 generation consists entirely of tall yellows. Precisely the same result is obtained by crossing a tall green with a dwarf yellow. In either case all the four characters involved are visible in one or other of the parents. Of every 16 plants produced by the tall yellow F1, 9 are tall yellows, 3 are tall greens, 3 are dwarf yellows, and 1 is a dwarf green. If we denote the tall and dwarf characters by A and a, and the yellow and green seed characters by B and b respectively, then the constitution of the F2 generation can be readily gathered from fig. 3.

2. When the two allelomorphic pairs affect the same structure we may get the phenomenon of novelities appearing in F1, and F2. Certain breeds of fowls have a "rose" and others a "pea" comb (fig. 4). On crossing the two a "walnut" comb results, and the offspring of such walnuts bred together consist of 9 walnuts, 3 roses, 3 peas, and 1 single comb in every 16 birds. This case may be brought into line with the scheme in fig. 3 if we consider the allelomorphic pairs concerned to
MENDELMISM

be rose (A) and absence of rose (a), and pea (B) and absence of pea (b). The zygotic constitution of a rose is therefore $AaBb$, and of a pea $aaBB$. A zygote containing both rose and pea is a walnut: a zygote containing neither rose nor pea is a single. The peculiar feature of such a case lies in the fact that absence of rose and absence of pea are the same thing, i.e. single; and this is doubtless owing to the fact that the characters rose and pea both affect the same structure, the comb.

3. Cases exist in which the characters due to one allelomorphic pair can only become manifest in the presence of a particular member of the other pair. If in fig. 3 the characters due to $B-b$ can only manifest themselves in the presence of $A$, it is obvious that this can happen in twelve cases out of sixteen, but not in the remaining four, which are homozygous for $aa$. An example of this is to be found in the inheritance of coat colour in rabbits, rats and mice where the allelomorphic pairs concerned are wild grey colour (B) dominant to black (b) and pigmentation (A) dominant to albinism (a). Certain albinos ($aaBB$) crossed with blacks ($AAbb$) give only greys ($AaBB$), and when these are bred together they give 9 greys, 3 blacks and 4 albinos. Of the 4 albinos 3 carry the grey character and 1 does not, but in the absence of the pigmentation factor (A) this is not visible. The ratio $9:3:3:1$ must be regarded as a $9:3:3:1$ ratio, in which the last two terms are visibly indistinguishable owing to the impossibility of telling by the eye whether an albino carries the character for grey or not.

4. The appearance of a zygotic character may depend upon the coexistence in the zygote of two unit-characters belonging to different allelomorphic pairs. If in the scheme shown in fig. 3 the manifestation of a given character depends upon the simultaneous presence of $A$ and $B$, it is obvious that of the 16 zygotes will present this character, whilst the remaining 7 will be without it. This is shown graphically in fig. 5, where the 9 squares have been shaded and the 7 left plain. The sweet pea offers an example of this phenomenon. White sweet peas breed true to whiteness, but when certain strains of whites are crossed the offspring are all coloured. In the next generation ($F_2$) these $F_1$ plants give rise to 9 coloured and 7 whites in every 16 plants. Colour here is a compound character whose manifestation depends upon the coexistence of two factors necessary to the production of colour. The ratio $9:7$ is in reality a $9:3:3:1$ ratio in which, owing to special conditions, the zygotes represented by the last three terms are indistinguishable from one another by the eye.

The phenomena of dihybridism, as illustrated by the four examples given above, have been worked out in many other cases for plants and animals. Emphasis must be laid upon the fact that, although the unit-characters belonging to two pairs may react upon one another in the zygote and affect its character, their inheritance is yet entirely independent. Neither grey nor black can appear in the rabbit—unless the pigmentation factor is also present; nevertheless, gametic segregation of this pair of characters takes place in the normal way among albino rabbits, though its effects are never visible until a suitable cross is made. In cases of trihybridism the Mendelian ratio for the forms appearing in $F_2$ is $27:9:9:9:3:3:3:1$; i.e. 27 showing dominance of three characters, three groups of 9 each showing dominance of two characters, three groups of 3 each showing dominance of one character, and a single individual out of 64 which is homozygous for all three recessive characters. It is obvious that the system can be indefinitely extended to embrace any number of allelomorphic pairs.

Reversion.—Facts such as those just dealt with in connexion with certain cases of dihybridism throw an entirely new light upon the phenomenon known as reversion on crossing. This is now seen to consist in the meeting of factors which had in some way or other become separated in phylogeny. The albino rabbit when crossed with the black "reverts" to the wild grey colour, because each parent supplies one of the two factors upon which the manifestation of the wild colour depends. So also the wild purple sweet pea may come as a reversion on crossing two whites. In such cases the reversion appears in the $F_2$ generation, because the two factors upon which it depends are the dominants of their respective allelomorphic pairs. Where the reversion depends upon the simultaneous absence of two characters it cannot appear until the $F_2$ generation. When fowls with rose and pea combs are crossed the reversionary single comb characteristic of the wild Gallus bankiva first appears in the $F_2$ generation.

Gametic Coupling.—In certain cases the distribution of characters in heredity is complicated by the fact that particular unit-characters tend to become associated or coupled together during gametogenesis. In no case have we yet a complete explanation of the phenomenon, but in view of the important

![Fig. 6.](image-url)
Chromosomes and Unit-Characters.—Breeding experiments have established the conception of definite unit-characters existing in the cells of an organism: in the cell histology has demonstrated the existence of small definite bodies—the chromosomes. During gametogenesis there takes place what many histologists regard as a differentiating division of the chromosomes: at the same period occurs the segregation of the unit-characters. Is there a relation of two-stage process between unit-character and the visible chromosome, and if so what is this relation? The researches of E. B. Wilson and others have shown that in certain Hemiptera the character of sex is definitely associated with a particular chromosome. The males of Pro-\textit{tector} possess thirteen chromosomes, and the qualitative division on gametogenesis results in the production of equal numbers of spermatozoa having six and seven chromosomes. The somatic number of chromosomes in the female is fourteen, and consequently all the mature ova have seven chromosomes. When a spermatozoon with seven chromosomes meets an ovum the resulting zygote has fourteen chromosomes and is a female; when a spermatozoon with six chromosomes meets an ovum the resulting zygote has thirteen chromosomes and is a male. In no other instance has any such definite relation been established, and in many cases at any rate it is certain that it could not be a simple one. The gametic number of chromosomes in wheat is eight, whereas the work of R. H. Biffen and others has shown that the number of unit-characters in this species is considerably greater. If therefore there exists a definite relation between the two it must be supposed that a chromosome can carry more than a single unit-character. It is not impossible that future work on gametic coupling may throw light upon the matter.

Heredity and Variation.—It has long been realized that the problems of heredity and variation are closely interwoven, and that whatever throws light upon the one may be expected to illuminate the other. Recent as has been the rise of the study of genetics, it has, nevertheless, profoundly influenced our views as to the nature of these phenomena. Heredity in now perceived to be a method of analysis, and the facts of heredity constitute a series of reactions which enable us to argue towards the constitution of living matter. And essential to any method of analysis is the recognition of the individuality of the individual. Constitutional differences of a radical nature may be concealed beneath apparent identity of external form. Purple sweet peas from the same pod, indistinguishable in appearance and of identical ancestry, may yet be fundamentally different in their constitution. From one may come purples, reds and whites, from another only purples and reds, from another purples and whites alone, whilst a fourth will produce only white flowers. If we further be required to take account of the radical differences in constitution which may underlie external similarity must necessarily be doomed to failure. Conversely, we realize to-day that individuals identical in constitution may yet have an entirely different ancestral history. From the cross between two fowls with rose and pea combs, each of irreproachable pedigree for generations, come single combs in the second generation, and these singles are precisely similar in their behaviour to singles bred from strains of unblemished ancestry. In the ancestry of the one is to be found no single over a long series of years, in the other none but singles occurred. The creature of given constitution may often be built up in many ways, but once formed it will behave like others of the same constitution. The one sure test of the constitution of a living thing lies in the nature of the gametes which it carries, and it is the analysis of these gametes which forms the province of heredity.

The clear cut and definite mode of transmission of characters first revealed by Mendel leads inevitably to the conception of a definite and clear-cut basis for these characters. Upon the structural basis, the unit-character, are grounded certain of the phenomena now termed variation. Varieties exist as such in virtue of differing in one or more unit-characters from
what is conventionally termed the type; and since these unit-characters must from their behaviour in transmission be regarded as discontinuous in their nature, it follows that the variation must be discontinuous also. A present tendency of thought is to regard the discontinuous variation or mutation as the material upon which natural selection works, and to consider that the process of evolution takes place by definite steps. Darwin's opposition to this view rested partly upon the idea that the discontinuous variation is more probably due to the rare偶然 occurrence, be unable to maintain itself against the swapping effects of intercrossing with the normal form. Mendel's work has shown that this objection is not valid, and the precision of the mode of inheritance of the discontinuous variation leads us to inquire if the small or fluctuating variation can be shown to have an equally definite physiological basis before it is admitted to play any part in the production of species. Until this has been shown it is possible to consider the discontinuous variation as the unit in all evolutionary change, and to regard the fluctuating variation as the uninherited effect of environmental accident.

The Human Aspect.—In conclusion we may briefly allude to certain practical aspects of Mendel's discovery. Increased knowledge of heredity means increased power of control over the living thing, and as we come to understand more and more the architecture of the plant or animal we realize what can and what cannot be done towards modification or improvement. The experiments of Biffen on the cereals have demonstrated what may be done with our present knowledge in establishing new, stable and more profitable varieties of wheat and barley, and it is impossible to doubt that as this knowledge becomes more widely disseminated it will lead to considerable improvements in the methods of breeding animals and plants.

It is not, however, in the economic field, important as this may be, that Mendel's discovery is likely to have most meaning for us: rather it is in the new light in which man will come to view himself and his fellow creatures. To-day we are almost entirely ignorant of the unit-characters that go to make the difference between one man and another. A few diseases, such as acaptonuria and congenital cataract, a digital malformation, and probably eye colour, are as yet the only cases in which inheritance has been shown to run upon Mendelian lines. The complexity of the subject must render investigation at once difficult and slow; but the little that we know to-day offers the hope of a great extension in our knowledge at no very distant time. If this hope is borne out, if it is shown that the qualities of man, his body and his intellect, his immunities and his diseases, even his very virtues and vices, are dependent upon the ascertainable presence or absence of definite unit-characters whose mode of transmission follows fixed laws, and if also man decides that his life shall be ordered in the light of this knowledge, it is obvious that the social system will have to undergo considerable changes.

Bibliography.—In the following short list are given the titles of papers dealing with experiments directly referred to in this article. References to most of the literature are to be found in (11), and a complete list to the date of publicaotion in (3).

of the same name, Mendelssohn's work possessed some of the charm of its Greek exemplar. What most impressed the German world was its beauty and lucidity of style—features to which Mendelssohn still owes his popularity as a writer. The Phidian was an immediate success, and besides being often reprinted in German, was speedily translated into nearly all the European languages, including English. The author was hailed as the "German Plato," or the "German Socrates"; royal and other aristocratic friends showered attentions on him, and it is no exaggeration to assert with Kayserling that "no stranger who came to Berlin failed to pay his personal respects to the German Socrates."

So far, Mendelssohn had devoted his talents to philosophy and criticism; now, however, an incident turned the current of his life in the direction of the cause of Judaism. Lavater was one of the most ardent admirers of Mendelssohn. He described him as "a companionable, brilliant soul, with piercing eyes, the body of an Aesop—a man of keen insight, exquisite taste and wide erudition... frank and open-hearted." Lavater was fired with the ambition to convert his friend to Christianity. In the preface to a German translation of Bonnet's "Christian Evidence, Lavater publicly challenged Mendelssohn to refute Bonnet or if he could not then "to do what wisdom, the love of truth and honesty must bid him, what a Socrates would have done if he had read the book and found it unanswerable." This appeal produced a painful impression. Bonnet resented Lavater's action, but Mendelssohn was bound to reply, though opposed to religious controversy. As he put it: "Suppose there were living among my contemporaries a Confucius or a Solon, I could, according to the principles of the latter's system, love and admire the great man without falling into the ridiculous idea that I must convert a Solon into a Confucius."

Here we see the germ of Mendelssohn's Pragmatism, to use the now current term. He shared this with Lessing; in this case, at all events, it is probable that the latter was indebted to Mendelssohn. But before discussing this matter, we must follow out the consequences of Lavater's Intrusion into Mendelssohn's affairs. The latter resolved to devote the rest of his life to the emancipation of the Jews. Among them secular studies had been neglected, and Mendelssohn saw that he could bestued the Jewish people by attacking it on the religious side. A great chapter in the history of culture is filled by the influence of translations of the Bible. Mendelssohn added a new section to this chapter by his German translation of the Pentateuch and other parts of the Bible. This work (1783) constituted Mendelssohn the Luther of the German Jews. From it, the Jews learned the German language; from it they imbued culture; with it there was born a new desire for German nationality; as a result of its popularity was inaugurated a new system of Jewish education. Some of the conservatives among the Jews opposed these innovations, but the current of progress was too strong for them. Mendelssohn was the first great champion of Jewish emancipation in the 18th century. He it was who induced C. G. Dohnm to publish in 1781 his epoch-making work, On the Civil Amelioration of the Condition of the Jews, a memorial which played a great part in the triumph of tolerance. Mendelssohn himself published a German translation of the Vindiciae judaorum by Menasseh ben Israel. The excitement caused by these proceedings led Mendelssohn to publish his most important contribution to the problems connected with the position of the Jews in relation to the general life. This work was the Jerusalem (1793; Eng. trans. 1838 and 1852). It is a forcible plea for freedom of conscience. Kant described it as "an irrefutable book." Its basic idea is that the state had no right to interfere with the religion of its citizens. As Kant put it, this was "the proclamation of a great reform, which, however, will be slow in manifestation and in progress, and which will affect not only your people but others as well." Mendelssohn asserted the pragmatic principle of the possible plurality of truths: that just as various nations need different constitutions—to one a monarchy, to another a republic, may be the most congenial to the national genius—so individuals may need different religions. The test of religion is its effect on conduct. This is the moral of Lessing's Nathan the Wise, the hero of which is undoubtedly Mendelssohn. The parable of the three rings is the epitome of the pragmatic position. One direct result of this pragmatism was unexpected. Having been taught that there is no absolutely true religion, Mendelssohn's own descendants—a brilliant circle, of which the musician Felix was the most noted—left the Synagogue for the Church. But despite this, Mendelssohn's thought was found to be a strengthening bond in Judaism. For he maintained that Judaism was less a "divine need, than a revealed life." In the first part of the 19th century, the criticism of Jewish dogmas and traditions was associated with a firm adhesion to the older Jewish mode of living. Reason was applied to beliefs, the historic consciousness to life. Modern reform in Judaism is parting to some extent from this conception, but it still holds good even among the liberals.

Of Mendelssohn's remaining years it must suffice to say that he progressed in fame numbering among his friends more and more famous men. His Mengenleben appeared in 1785, and he died as the result of a cold contracted while carrying to his publishers in 1786 the manuscript of a vindication of his friend Lessing, who had predeceased him by five years.

Mendelssohn had six children. His sons were: Joseph (founder of the Mendelssohn banking house, and a friend and benefactor of Alexander Humboldt), whose son Alexander (d. 1871) was the last Jewish descendant of the philosopher; Abraham (who married Leah Bartholdy and was the father of Fanny Hensel and J. L. Felix Mendelssohn Bartholdy); and Nathan (a mathematical engineer of considerable repute). His daughters were Dorothea, Recha and Henriette, all brilliantly gifted women.

MENDELSSOHN-BARTHOLDY, Jakob Ludwig Felix (1809-1847), German composer, grandson of Moses Mendelssohn (q.v.), was born in Hamburg on the 3rd of February 1809. In consequence of the troubles caused by the French occupation of Hamburg, Abraham Mendelssohn, his father, migrated in 1811 to Berlin, where his grandmother Fromet, then in the twenty-fifth year of her widowhood, received the whole family into her house, No. 7 Neue Promenade. Here Felix and his sister Fanny received their first instruction in music from their mother, under whose care they progressed so rapidly that their exceptional talent soon became apparent. Their next teacher was Madame Bigot, who, during the temporary residence of the family in Paris in 1816, gave them valuable instruction. On their return to Berlin they took lessons in thoroughbass and composition from Zelter, in pianoforte-playing from Ludwig Berger, and in violin-playing from Henning—the care of their general education being entrusted to the father of the novelist Paul Heyse.

Felix first played in public on the 24th of October 1818, taking the pianoforte part in a trio by Woelfl. On the 11th of April 1819 he entered the Berlin Singakademie as an alto, and in the following year began to compose with extraordinary rapidity. His earliest dated work is a cantata, In rührend feierlichen Tönen, completed on the 13th of January 1820. During that year alone he produced nearly sixty movements, including songs, pianoforte sonatas, a trio for pianoforte, violin and violoncello, a sonata for violin and pianoforte, pieces for the organ, and even a little dramatic piece in three scenes. In 1821 he wrote five symphonies for stringed instruments, each in three movements; motets for four voices, an
MENDELSSOHN-BARTHOLDY

opera, in one act, called Soldatenliebschaft; another, called Die beiden Pädagogen; part of a third, called Die wandernden Comedi-anten; and an immense quantity of other music of different kinds, all showing the precocity of his genius. The original autograph copies of these early productions are preserved in the Berlin Library, where they form part of a collection which fills forty-four large volumes, all written with infinite neatness, and for the most part carefully dated—a sufficient proof that the methodical habits which distinguished his later life were formed in early childhood.

In 1821 Mendelssohn paid his first visit to Goethe, with whom he spent sixteen days at Weimar, in company with Zelter. From this year also dates his first acquaintance with Weber, who was then in Berlin superintending the production of Der Freischütz; and from the summer of 1822 his introduction, at Cassel, to another of the greatest of his contemporaries, Ludwig Spohr. During this year his pen was even more prolific, producing, among other works, an opera, in three acts, entitled Die beiden Neffen, oder der Onkel aus Boston, and a pianoforte concerto, which he played in public at a concert given by Frau Anna Mildor.

It had long been a custom with the Mendelssohn family to give musical performances on alternate Sunday mornings in their dining-room, with a small orchestra, which Felix always conducted, even when he was not tall enough to be seen without standing upon a stool. For each of these occasions he produced some new work—playing the pianoforte pieces himself, or entrusting them to Fanny, while his sister Rebecca sang, and his brother Paul played the violoncello. In this way Die beiden Neffen was first privately performed, on the fiftieth anniversary of his birthday, the 3rd of February 1824. Between the 3rd and the 31st of March in this year he composed his fine symphony in C minor, now known as Op. 10, and soon afterwards the quartet in B minor, Op. 3, and the (posthumous) pianoforte sextet, Op. 110. In this year also began his lifelong friendship with Moscheles, who, when asked to write him a pupil, said, "If he wishes to take a hint from me, as to anything new to him, he can easily do so; but he stands in no need of lessons."

In 1825 Abraham Mendelssohn took Felix to Paris, where among other musicians then resident in the French capital he met the two most popular dramatic composers of the age, Rossini and Meyerbeer, and lived on terms of intimacy with Hummel, Kalkbrenner, Rode, Baillot, Herz, and many other artists of European celebrity. On this occasion also he made his first acquaintance with Cherubini, who, though he rarely praised any one, expressed a high opinion of his talent, and recommended him to write a Kyrie, for five voices, with full orchestral accompaniments, which he himself described as "exceeding in thickness" anything he had attempted. From letters written at this period we learn that Felix's estimate of the French school of music was far from flattering; but he formed some friendships in Paris, which were renewed on later occasions.

He returned to Berlin with his father in May 1825, taking leave of his Parisian friends on the 19th of the month, and interrupting his journey at Weimar for the purpose of paying a second visit to Goethe, to whom he dedicated his quartet in B minor. On reaching home he must have worked with greater zeal than ever; for on the 10th of August in this same year he completed an opera, in two acts, called Die Hochzeit des Comacho, a work of considerable importance.

No ordinary boy could have escaped uninjured from the snares attendant upon such a life as that which Mendelssohn now lived. Notwithstanding his overwhelming passion for music, his general education had been so well cared for that he was able to hold his own, in the society of his seniors, with the grace of an accomplished man of the world. He was already recognized as a leading spirit by the artists with whom he associated; and these artists were men of acknowledged talent and position. The temptations to egotism by which he was surrounded would have rendered most clever students intolerable. But the natural amiability of his disposition, and the healthy influence of his happy home-life, counteracted all tendencies towards self-assertion.

Soon after his return from Paris, Abraham Mendelssohn removed from his mother's residence to No. 3 Leipziger Strasse, a roomy, old-fashioned house, containing an excellent music-room, and in the grounds adjoining a "Gartenhaus" capable of accommodating several hundred persons at the Sunday performances.\(^1\) In the autumn of the following year this "garden-house" witnessed a memorable private performance of the work by means of which the greatness of Mendelssohn's genius was first revealed to the outer world—the overture to Shakespeare's Midsummer Night's Dream. The finished score of this famous composition is dated "Berlin, August 6, 1826"—its author was only seventeen and a half years old. Yet in no later work does he exhibit more originality of thought, more freshness of conception, or more perfect mastery over the details of technical construction, than in this delightful inspiration.

The overture was first publicly performed at Stettin, in February 1827, of the invention of the young composer, who was at once accepted as the leader of a new and highly characteristic manifestation of the spirit of progress. Henceforth we must speak of him, not as a student, but as a mature and experienced artist.

Meanwhile Camacho's Wedding had been submitted to Spontini, with a view to its production at the opera. The libretto, founded upon an episode in the history of Don Quixote, was written by Klingemann, and Mendelssohn threw himself into the spirit of the romance with a keen perception of its peculiar humoral tendencies. The work was completed the month of his father's return from Stettin, produced on the 29th of April 1827, and received with great apparent enthusiasm; but a cabal was formed against it, and it never reached a second performance. The critics abused it mercilessly; yet it exhibits merits of a very high order. The solemn passage for the trombones, which heralds the first appearance of the knight of La Mancha, is conceived in a spirit of reverent appreciation of the idea of Cervantes, which would have done honour to a composer of lifelong experience.

Mendelssohn was annoyed at this injustice, and some time elapsed before his mind recovered its usual bright tone; but he continued to work diligently. Among other serious undertakings, he formed a choir for the study of the choral works of Sebastian Bach, then unknown to the public; and, in spite of Zelter's opposition, he succeeded, in 1829, in inducing the Berlin Singakademie to give a public performance of the Passion according to St Matthew, under his direction, with a chorus of between three and four hundred voices. The scheme succeeded beyond his warmest hopes, and proved the means of restoring to the world great compositions which had never been heard since the death of Bach; but the obstructive party were offended; and at this period Mendelssohn was far from popular among the musicians of Berlin.

In April 1829 Mendelssohn paid his first visit to London. His reception was enthusiastic. He made his first appearance before an English audience at one of the Philharmonic Society's concerts—then held in the Argyll Rooms—on the 25th of May, conducting his symphony in C minor from the pianoforte, to which he was led by John Cramer. On the 30th he played Weber's Concertstück, from memory, a proceeding at that time extremely unusual. At a concert given by Drouet, on the 24th of June, he played Beethoven's pianoforte concerto in E flat, which had never before been heard in the country; and the overture to A Midsummer Night's Dream was also, for the first time, presented to a London audience. On returning home from the concert, Attwood, then organist of St Paul's Cathedral, left the score of the overture in a hackney coach, whereupon Mendelssohn wrote out another, from memory, without an error. At another concert he played, with Moscheles, his still unpublished concerto in E, for two pianofortes and
orchestra. After the close of the London season he started with Klingemann on a tour through Scotland, where he was inspired with the first idea of his overture to The Isles of Fingal, returning to Berlin at the end of November. Except for an accident to his knee, which lamed him for some time, his visit was highly successful and laid the foundation of many friendships and plans in March. His compositions.

The visit to England formed the first division of a great scheme of travel which his father wished him to extend to all the most important art centres in Europe. After refusing the offer of a professorship at Berlin, he started again, in May 1830, for Italy, pausing on his way at Weimar, where he spent a fortnight with Goethe, and reaching Rome, after many pleasant interruptions, on the 1st of November. No excitement prevented him from devoting a certain time every day to composition; but he lost no opportunity of studying either the countless treasures which form the chief glory of the great city or the manners and customs of modern Romans. He attended, with insatiable curiosity, the services in the Sistine Chapel; and his keen power of observation enabled him to throw much interesting light upon them. His letters on this subject, however, lose much of their value through his incapacity to comprehend the close relation existing between the music of Palestina and his contemporaries and the ritual of the Roman Church. His Lutheran education kept him in ignorance even of the first principles of ordinary chanting; and it is amusing to find him describing as enormities peculiar to the papal choral customs familiar to every village singer in England, and as closely connected with the structure of the "Anglican chant" as with that of "Gregorian music." Still, though he could not agree in all points with Baini, the greatest ecclesiastical musician then living, he shared his admiration for the Improperia, the Miserere, and the cantus planus of the Lamentations and the Exultet, the musical beauty of which he could understand, apart from their ritual significance.

In passing through Munich on his return in October 1831 he composed and played his pianoforte concerto in G minor, and accepted a cornet pension (never fulfilled) to compose an opera for the Munich theatre. Pausing for a time at Stuttgart, Frankfort and Düsseldorf he arrived in Paris in December, and passed four pleasant months in the renewal of acquaintances formed in 1825, and in close intercourse with Liszt and Chopin. On the 10th of February 1832 the overture to A Midsummer Night's Dream was played at the conservatoire, and many of his other compositions were brought before the public; but he did not escape disappointments with regard to some of them, especially the Reformation symphony, and the visit was brought to a close by an attack of choleran, from which, however, he rapidly recovered.

On the 23rd of April 1832 he was again in London, where he twice played his G minor concerto at the Philharmonic concerts, gave a performance on the organ at St Paul's, and published his first book of Lieder ohne Worte. He returned to Berlin in July, and during the winter he gave public performances of his Reformation symphony, his concerto in G minor, and his Walpurgisnacht. In the following spring he paid a third visit to London for the purpose of conducting his Italian symphony, which was played for the first time, by the Philharmonic Society, on the 13th of May 1833. On the 26th of the same month he conducted the performances at the Lower Rhine festival at Düsseldorf with such brilliant effect that he was at once offered, and accepted, the appointment of general-music-director to the town, an office which included the management of the music in the principal churches, at the theatre, and at the rooms of two musical associations.

Before entering upon his new duties, Mendelssohn paid a fourth visit to London, with his father, returning to Düsseldorf on the 27th of September 1833. His influence produced an exceedingly effect upon the church music and in the concert-room; but his relations with the management of the theatre were not altogether pleasant; and it was probably this circumstance which first led him to forsake the cultivation of the opera for that of sacred music. At Düsseldorf he first designed his famous oratorio St Paul, in response to an application from the Cæcilien-Verein at Frankfort, composed his overture to Die schöne Melusine, and planned some other works of importance. He liked his appointment, and would probably have retained it much longer had he not been invited to undertake that great direct action which then became the best course at Leipzig, and thus raised to the highest position attainable in the German musical world. To this new sphere of labour he removed in August 1835, opening the first concert at the Gewandhaus, on the 4th of October, with his overture Die Meerestille, a work possessing great attractions, though by no means on a level with the Midsummer Night's Dream, The Isles of Fingal, or Melusine.

Mendelssohn's reception in Leipzig was most enthusiastic; and under their new director the Gewandhaus concerts prospered exceedingly. Meanwhile St Paul steadily progressed, and was first produced, with triumphant success, at the Lower Rhine festival at Düsseldorf, on the 22nd of May 1836. On the 3rd of October it was first sung in English, at Liverpool, under the direction of Sir George Smart; and on the 16th of March 1837 Mendelssohn again directed it at Leipzig.

The next great event in Mendelssohn's life was his happy marriage, on the 28th of March 1837, to Cecile Charlotte Sophie Jeannenau. The honeymoon was scarcely over before he was again summoned to England to conduct St Paul, at the Birmingham Music Festival, on the 13th of May. Meanwhile, he played on the organ at St Paul's and at Christ Church, Newgate Street, with an effect which exercised a lasting influence upon English organists. It was here also that he first contemplated the production of his second oratorio, Elijah.

Passing over the composition of the Lobgesang in 1840, a sixth visit to England in the same year, and his inauguration of a scheme for the erection of a monument to Sebastian Bach, we find Mendelssohn in 1841 recalled to Berlin by the king of Prussia, with the title of Kapellmeister. Though his appointment resulted in the production of Antigone, Oedipus Coloneus, Athalie, the incidental music to the Midsummer Night's Dream, and other great works, it proved an endless source of vexation, and certainly helped to shorten the composer's life. In 1842 he came to England for the seventh time, accompanied by his wife, conducted his Scotch symphony at the Philharmonic, again played the organ at St Peter's, Cornhill, and Christ Church, Newgate Street, and was received with honour by the queen and the prince consort. He did not, however, permit his new engagements to interfere with the direction of the Gewandhaus concerts; and in 1843 he founded in Leipzig the Gewandhaus orchestra, which soon became the best musical college in Europe, opening it on the 3rd of April in the buildings of the Gewandhaus. In 1844 he conducted six of the Philharmonic concerts in London, producing his new Midsummer Night's Dream music, and playing Beethoven's pianoforte concerto in G with extraordinary effect. He returned to his duties at Berlin in September, but succeeded in persuading the king to free him from his most onerous engagements.

After a brief residence in Frankfort, Mendelssohn returned to Leipzig in September 1845, resuming his old duties at the Gewandhaus, and to the general consternation of the concerts at Berlin.

Before entering upon his new duties, Mendelssohn paid a fourth visit to London, with his father, returning to Düsseldorf on the 27th of September 1833. His influence produced an exceedingly effect upon the church music and in the concert-room; but his relations with the management of the theatre were not altogether pleasant; and it was probably this circumstance which first led him to forsake the cultivation of the opera for
But the exertion was beyond his strength. He witnessed Jenny Lind's first appearance at Her Majesty's Theatre, on the 4th of May, and left England on the 9th, little anticipating the trial that awaited him in the tidings of the sudden death of his sister Fanny, which reached him only a few days after his arrival in Frankfort. The loss of his mother in 1842 had shaken him much, but the suddenness with which this last and most unexpected calamity overtook him down. He fell to the ground insensible, and never fully recovered. In June he was so far himself again that he was able to travel, with his family, by short stages, to Interlaken, where he stayed for some time, illustrating the journey by a series of water-colour drawings, but making no attempt at composition for many weeks. He returned to Leipzig in September, bringing with him fragments of Christus, Loredel, and some other unfinished works, taking no part in the concerts, and living in privacy. On the 9th of October he called on Madame Frege, and asked her to sing his latest set of songs. She left the room for lights, and on her return found him in violent pain and almost insensible. He lingered for four weeks, and on the 4th of November he passed away, in the presence of his wife, his brother, and his three friends, Moscheles, Schleinitz, and Ferdinand David. A cross marks the site of his grave, in the Alte Dreialtigtsgck Kirchhof, at Berlin.

Mendelssohn's title to a place among the great composers of the century is incontestable. His style, though differing little in technical execution from that of his predecessors, is characterized by a vein of melody peculiarly his own, and easily distinguishable by those who have studied his works, not only from the genuine effusions of contemporary writers, but from the most successful of the servile imitations with which, even during his lifetime, the music-shops were deluged. In less judicious hands the rigid symmetry of his phrasing might, perhaps, have palp ed upon the ear; but under his skilful management it serves only to impart an additional charm to thoughts which derive their chief beauty from the evident spontaneity of their conception. In this, as in all other matters of a purely technical character, he regarded the accepted laws of art as the medium by which he might most certainly attain the ends dictated by the inspiration of his genius. Though caring nothing for rules, except as means for producing a good effect, he scarcely ever violated them, and was never weary of impressing their value upon the minds of his pupils. His method of counterpoint was modelled in close accordance with that practised by Sebastian Bach. This he used in combination with an elastic development of the sonata-form, similar to that engraved by Beethoven upon the lines laid down by Haydn. The principles involved in this arrangement were strictly conservative; yet they enabled him, at the very outset of his career, to invent a new style no less original than that of Schubert or Weber, and no less remarkable as the embodiment of canons already consecrated by classical authority than as a special manifestation of individual genius. It is thus that Mendelssohn stands before us as at the same time a champion of conservatism and an apostle of progress; and it is chiefly by virtue of these two apparently incongruous though really compatible phases that his influence and example availed, for so many years, to hold in check the violence of reactionary opinion which injudicious partisanship afterwards fanned into revolutionary fury.

Concerning Mendelssohn's private character there have never been two opinions. As a man of the world he was more than ordinarily accomplished—brilliant in conversation, and in his lighter moments overflowing with sparkling humour and ready pleasantry, loyal and unselfish in the more serious business of life, and never weary of working for the general good. As a friend he was unvaryingly kind, sympathetic and true. His earnestness as a Christian needs no stronger testimony than that afforded by his own delineation of the character of St Paul; but it is not too much to say that his heart and life were pure as those of a little child. (W. S. R.)

This article has the unique value of being the record of the eminent musical scholar who was an actual pupil of Mendelssohn. From the richness of his preparations and the perfect regulation of the value of such a record, must have proceeded a man whom even his contemporaries knew to be greater than all his works. Mendelssohn's aristocratic horror of self-advertisement unites him for truth in the story of his life, but happily. Happily, it was not accidental: it was the outcome of a long and inopportunely, when his own powers, like Handel's at the same age, were being wasted on pseudo-classical forms; the new art was not yet ripe; and in the early Wagner-Liszt reign of terror his was the audacity to set up in revolt against them. This from the pen of the "Romantic" pioneer Schumann soon followed; but, as being more difficult to explain away, and more embarrassing to irreverence and conceit, it remains a subject of controversy. Meanwhile Mendelssohn's reputation, except as the composer of a few inexplicably beautiful and original orchestral pieces, has vanished and been released by a pure fiction known as the "Mendelssohn tradition" of orchestral conducting. This for some time was the distorted version made by Wagner on his experiences of English orchestral playing, remarks which, though not very good-natured, do not bear the full construction popularly imputed to them. If Beethoven had come and conducted in England, Mendelssohn's expostulations with careless players would have been met by references to the "Beethoven tradition"; and, if Wagner had shared Mendelssohn's reluctance to putting on record remarks likely to wound individual, professional and national sensibilities, it might not have been impossible that reproaches against slipshod and mechanical playing might nowadays be met by references to the "Wagner tradition.

Mendelssohn's influence on the early career of Joachim, next to his work in Bach, his genius is most consequent to later musical history. Those many profound and sincere admirers to Joachim to whom the name of Mendelssohn calls up only the Widow in Elbou and the weaker Songs without Words, may find no more strange; but there is no doubt that Joachim found the continuation of a true Mendelssohn tradition as identifiable with his own efforts to "uphold the dignity of art." (D. F. T.)

MENDES, CATULLE (1841-1900), French poet and man of letters, of Jewish extraction, was born at Bordeaux on the 22nd of May 1841. He early established himself in Paris, attaining speedy notoriety by the publication in the Revue Fantaisiste (1861) of his "Roman d'une nuit," for which he was condemned to a minor imprisonment, and fined 100 francs, and by a series of verses and short stories, in the latter of which he continues the French tradition of the licentious conte. For the theatre he wrote: La Part du roi (1872), a one-act verse comedy; Les Frères d'armes (1873), drama; Justice (1877), in three acts, characterized by a hostile critic as a hymn in praise of suicide; the libretto of a light opera, Le Capitaine Fracasse (1878), founded on Théophile Gautier's novel; La Femme de Tabarin (1882); Médée (1888), in three acts and in verse; La Reine Élamérite (1880), a comic dra matique in six acts and in verse, the scene of which is laid in the land of the Huns; and three plays in prose, one of which is Bar-Cochebas, the Syrian pseudo-Messiah, for the music of C. Erlanger; Scarron (1905); Ariane (1906), for the music of Massenet; and Glatigny (1906). His critical work includes: Richard Wagner (1886); L'Art au théâtre (3 vols., 1896-1900), a series of dramatic criticisms reprinted from newspapers; and a report addressed to the minister of public instruction and of the fine arts on Le Mouvement poétique français de 1857 à 1900 (new ed., 1903), which includes a bibliographical and critical dictionary of the French poets of the 19th century. Perhaps the most famous of his novels are: Le Roi vierge (1880) in which he introduces Louis II. of Bavaria and Richard Wagner; La Maison de la viole (1894), and Gog (1897). He married in 1866 Mlle Judith Gautier, younger daughter of the poet, from whom he was subsequently separated.
On the 9th of February 1909, early in the morning, his dead body was discovered in the railway tunnel of Saint Germain. He had left Paris by the midnight train on the 7th, and it is supposed that, thinking he had arrived at the station, he had opened the door of his compartment while still in the tunnel.

**MENDICANCY** (from Lat. mendicus, in a condition of beggary, a word of unknown origin), a state or condition of being a beggar, the practice of obtaining a livelihood by asking alms. The word "mendicant," also found in the French form "mendiant," appears to have come into use in the sense of begging friar.

**MENDICANT MOVEMENT AND ORDERS.** The facts concerning the rise of the Orders of Mendicant Friars are related in the articles on the several orders (Franciscans, Dominicans, Carmelites, Augustinian Hermits), and in that on Monasticism (§ 11), where the difference between friars and monks is explained. The purpose of this article is to characterize the movement as a whole, and to indicate the circumstances that produced it. The most striking phenomenon in connexion with the beginnings of the mendicant orders is the rapidity with which the movement spread. Within a generation of the death of the two men who, when they retired to Assisi (1226), their institutes had spread all over Europe and into Asia, and their friars could be numbered by tens of thousands. In all the great cities of Western Europe friaries were established, and in the universities theological chairs were held by Dominicans and Franciscans. And when at the middle of the century the other great mendicant orders of Carmelites and Austin Friars, and also Servites (q.v.) arose their propagation showed that the possibilities of the mendicant movement had not been exhausted by the Dominicans and Franciscans. Lesser mendicant orders sprang up in all directions—Gasquet mentions half a dozen such that found their way into England (English Monastic Life, p. 241)—in such numbers that the Council of Lyons in 1274 seemed it necessary to suppress all except the orders already named. Moreover, besides the various orders of friars, there were the lay Tertiaries that arose and spread far and wide in connexion with the Franciscans and other mendicants, and the similar institute of the Humiliati (see Tertiaries). These facts clearly show that the Mendicant Movement responded to widely spread and deeply felt needs of the time. These needs found expression not only in the Mendicant orders within the Church, but also in a number of lay religious and revolutionary religious sects. There was this in common among the Cathari, Waldenses, Albigenases and other heretical bodies that overran so many parts of Western Europe in the second half of the 13th century and the beginning of the 13th, that they all inveighed against the wealth of the clergy, and preached the practice of austere poverty and a return to the simple life of Christ and the Apostles. Thus the sectaries no less than the Mendicant orders bear witness to the existence of spiritual needs in Western Christendom, which the Mendicant orders went a long way towards satisfying. Probably the most crying need was that of priests to minister to the great city populations, at that time growing up with such rapidity, especially in Italy. During the 12th, 13th and 12th centuries the Church had been organized on the lines of the prevailing feudal system—the bishops and abbots were feudal barons, and the effects of the system were felt throughout the ranks of the lower clergy. The social fabric was built up not on the towns, but on the great landlords; and when the centre of gravity began to move, first of all in Italy, to the towns, and crowded populations began to be massed together in them, the parochial systems broke down under the weight of the new conditions, and the people were in a state of spiritual and moral no less than physical destitution. So, when the friars came and established themselves in the poorest localities of the towns, and brought religion to the destitute and the outcasts of society, assimilating themselves to the conditions of life of those among whom they worked, they supplied a need with which the parochial clergy were unable to cope.

The friars responded not only to the new needs of the age, but to its new ideas—religious, intellectual, social, artistic. It was a period of religious revival, and of reaction against abuses that followed in the wake of the feudal system; and this religious movement was informed by a new mysticism—a mysticism that fixed its attention mainly on the humanity of Christ and found its practical expression in the imitation of His life. A new intellectual wave was breaking over Western Europe, symbolized by the university and the scholastic movements; and a new spirit of democratic freedom was making itself felt in the growing commercial towns of Italy and Germany. There is no need to labour the point that the Mendicants responded to these needs and needs alone. They did not reject Catholic Christianity, for the fact lies upon the surface of history. But a few words are necessary on the central idea from which the Mendicants received their name—the idea of poverty. This was St Francis's root idea, and there is no doubt—that it was borrowed from him by St Dominic and the other Mendicant founders. St Francis did not intend that begging and alms should be the normal means of sustenance for his friars; on the contrary, he intended them to live by the work of their hands, and only to have recourse to begging in extraordinary cases. But as the friars soon came nearly all to rely on public charity and to spiritual ministrations, and the communities grew larger, it became increasingly difficult for them to support themselves by personal work; and so the begging came to play a greater role than had been contemplated by St Francis. But his idea certainly was that his friars should not only practise the utmost personal poverty and simplicity in their life, but that they should have the minimum of possessions—no lands, no funded property, no fixed sources of income. The maintaining of this ideal has proved unworkable in practice. In the Dominican Order and the others that started as mendicant it has been mitigated or even abrogated. Among the Franciscans themselves it has been the occasion of endless strife, and has been kept alive only by dint of successive reforms and fresh starts, each successful for a time, but doomed always, sooner or later, to yield to the inexorable logic of facts. The Capuchins (q.v.) have made the most permanently successful effort to maintain St Francis's ideal; but even among them mitigations have had to be admitted. In spite, however, of all mitigations the Franciscans have nearly always presented to the world the idea of begging inevitably come to poverty by the poorness and simplicity of their lives and surroundings.

On the subject-matter of this article the best thing in English is the Introductory Essay by the Capuchin Fr. Cuthbert on "The Spirit and Genius of the Franciscan Friars," in The Friars and how they came to England (1903); see also the earlier chapters of Emil Gebhard's Italic mystique (1895). (E. C. B.)

**MENDIP HILLS,** a range in the north of Somersetshire, England. Using the name in its widest application, the eastern boundary of the range may be taken to be formed by the upper valleys of the rivers Frome and Brue, and the depression between them. The range extends from these northward with a major axis of about 23 m., while the outliers of Waverling Down and Bleadon Hill continue it towards the shore of the Bristol Channel. The range is generally about 6 m. in width, and its total area about 130 sq. m. Its south-western face descends to the low "moors" or marshes drained by the Axe and other streams, the small towns of Axbridge, Cheddar and Wells lying at the foot of the hills. Towards the north-east its limits are less clearly defined, for high ground, intersected by narrow vales, extends as far as the valley of the Axe, which, depressed, followed by the road between Radstock and Wells, strikes across the range about its centre; the principal elevations lie west of this, and to the area thus defined the name of the Mendips is sometimes restricted. The summit of the hills is a gently swelling plateau, which reaches its extreme height in the north—1068 ft. The Mendips consist principally of Carboniferous Limestone. Fine cliffs and scarps occur on the flanks of the plateau, as in the gorge of Cheddar, and there is a wonderful series of caverns, the result of water action. The surface of the plateau is often broken by deep holes.
MENDOZA, A. H. DE—MENDOZA, P. G. DE

("swallets") into which streams flow. Some of the caves, such as those at Cheddar, are easy of access, and attract many visitors owing to the beauty of the stalactitic formations; others, of greater extent and grandeur, have only been explored, or partly explored, with great difficulty. Some caves have yielded large quantities of animal remains (hyaenid as well as others) associated with traces of prehistoric human occupation. Among such Wookey Hole, where the river Axe issues from the foot of a cliff, may be mentioned. Lead was worked among the Mendips at a very early period. Some of the Roman workings, especially in the neighbourhood of Charterhouse-on-Mendip, have yielded pigs of lead inscribed with the names of emperors of the 1st and 2nd centuries A.D., together with an abundance of smaller objects.

MENDOZA, ANTONIO HURTADO DE (1593?–1644), Spanish dramatist, was born about the end of the 16th century in the province of Asturias, became page to the count of Saldaña (son of the duke de Lerma), and was recognized as a rising poet by Cervantes in the Viaje del Paraiso (1614). He rose rapidly into favour under Philip IV., who appointed him private secretary, commissioned him comedias palaciegas for the royal theatre at Aranjuez, and in 1623 conferred on him the orders of Santiago and Calatrava. Most of his contemporaries and rivals paid court to "el discreto de palacio," and Mendoza seems to have lived in the freEST terms with all his brothers and descendants except Ruiz de Alarcón. He is said to have been involved in the fall of Olivares, and died unexpectedly at Saragossa on the 19th of September 1644. Only one of his plays, Querer por sólo querer, was published with his consent; it is included in a volume (1625) containing his semi-official account of the performances at Aranjuez in 1622. The best edition of Mendoza’s plays and verses bears the title of Obras litúricas y cómicas, divinas y humanas (1728). Much of his work does not rise above the level of graceful and accomplishé verse; but that he had higher qualities is shown by El Marido hace mujer, a brilliant comedy of manners, which forms the chief source of Molíre’s École des maris.

The Fiesta que se hizo en Aranjuez y Querer por sólo querer were translated into English by Sir Richard Fanshawe, afterwards ambassador at Madrid, in a posthumous volume published in 1671.

MENDOZA, DIEGO HURTADO DE (1503–1573), Spanish novelist, poet, diplomatist and historian, a younger son of the count of Tendillas, governor of Granada, was born in that city in 1503. The celebrated marquis of Santillana was his great-grandfather. On leaving the university of Salamanca, Mendoza determined on the profession of taking orders, served under Charles V. in Italy, and attended lectures at the universities of Bologna, Padua and Rome. In 1537 he was sent to England to arrange a marriage between Henry VIII. and the duchess of Milan, as well as a marriage between Prince Louis of Portugal and Mary Tudor. Despite the failure of his mission, he preserved the confidence of the emperor, and in 1539 was appointed ambassador at Venice; there he patronized the Aldi, procured copies of the Greek manuscripts belonging to Cardinal Bessarion, and acquired other rare codices from the monastery of Monte Cassino. The first edition of Josephus was printed (1544) from the texts in Mendoza’s collection. He acted for some time as military governor of Siena, represented Spain diplomatically at the council of Trent, and in 1547 was nominated special plenipotentiary at Rome, where he remained till 1554. He was never a favourite with Philip II., and a quarrel with a courtier resulted in his banishment from court (June 1568). The remaining years of his life, which were spent at Granada, he devoted to the study of Arabic, to poetry, and to his history of the Moorish insurrection of 1568–1570. He died in 1575.

His Guerra de Granada was published at Lisbon by Luis Tribulhos de Toledo in 1647; the delay was doubtless due to Mendoza’s severe criticism of contemporaries who survived him. In some passages the author deliberately imitates Sallust and Tacitus; his style is, on the whole, vivid and trenchant, his information is exact, and in critical insight he is not inferior to Mariana. The attribution to Mendoza of Lázaro de Tormes is rejected by all competent scholars, but that he excelled in picareseque malice is proved by his indecorous verses written in the old Castilian metres and in the more elaborate measures imported from Italy. Menéndez y Pelayo believed to be the author of the letters to Feliciano de Silva and to Captain Salazar, published by Antonio Paz y Melia in Sales Españoles (Madrid, 1900).

MENDOZA, PEDRO GONZALEZ DE (1428–1493), Spanish cardinal and statesman, was the fourth son of Iñigo Lopez de Mendoza, marqués de San Millán, and doña Elvira de Rances. He was born at Guadalajara in New Castle, the chief lordship of his family, on the 3rd of May 1428. The house of Mendoza claimed to descend from the lords of Llodio in Alava, and to have been settled in Old Castle, in the 11th century. One chief of the house had been greatly distinguished at the battle of the Navas de Tolosa in 1212. Another had been Admiral of Castile in the reign of Alphonso the Wise. Peter the Cruel had endowed them with the lordships of Hita and Buitrago. The greatness of the Mendozas was completed by Pedro Gonzalez, who sacrificed his life to save King John I. at the battle of Aljubarrota in 1388. A page of the court, he was fated to lose the title he bore for the greater part of his life—was a poet, and was conspicuous during the troubled reign of John II. Loyalty to the Crown was the traditional and prevailing policy of the family. Pedro Gonzalez, the future cardinal, was sent into the Church mainly because he was a younger son and that he might be handsomely provided for. He had no vocation, and was an example of the worldly, political and martial preludes of the 15th century. In 1452, at the age of twenty-four, he was chosen by the king John II. to be bishop of Calahorra, but did not receive the pope’s bull till 1454. As bishop of Calahorra, he was also sefer, or civil and military ruler, of the town and its dependent district. In his secular capacity he led the levies of Calahorra in the civil wars of the reign of Henry IV. He fought for the king at the second battle of Olmedo on the 20th of August 1467, and was wounded in the arm. During these years he became attached to Doña Mencia de Lemos, a Portuguese lady-in-waiting of the queen. She bore him two sons, Rodrigo, who was once selected to be the husband of Lucrezia Borgia, and Diego, who was the grandfather of the princess of Eboli of the reign of Philip II. (see Perez, Avrónico). By another lady of a Valladolid family he had a third son, not afterword an important figure: by this lady he became bishop of Siguenza. In 1473 he was created cardinal, was promoted to the archbishopric of Seville and named chancellor of Castile. During the last years of the reign of King Henry IV. he was the partisan of the Princess Isabella, afterwards queen. He fought for her at the battle of Toro on the 1st of March 1476; had a prominent part in placing her on the throne; and served her indefatigably in her efforts to suppress the disorderly nobles of Castile. In 1482 he became archbishop of Toledo. During the conquest of Granada he contributed largely to the maintenance of the army. On the 2nd of January 1492 he occupied the town in the name of the Catholic sovereigns. Though his life was worldly, and though he was more soldier and statesman than priest, the “Great Cardinal,” as he was commonly called, did not neglect his duty as a bishop. He used his influence with the queen and also at Rome to arrange a settlement of the disputes between the Spanish sovereigns and the papacy. Though he maintained a splendid household as archbishop of Toledo, and provided handsomely for his children, he devoted part of his revenue to charity, and with part he endowed the college of Santa Cruz de Valladolid. His health broke down at the close of 1492, and he died at Rome on the 13th of January 1492.
a man who had no likeness to himself save in political faculty and devotion to the authority of the Crown. He died at Guadalajara on the 11th of January 1495.

The life of the cardinal, by Salazar de Mendoza, *Cronica del gran cardenal Don Pedro Gonzales de Mendoza* (Toledo, 1625), is discursive and garrulous but valuable. See also Prescott, *History of Ferdinand and Isabella*.

**MENDOZA**, a province of western Argentina, bounded N. by San Juan, E. by San Luis and the territory of La Pampa, S. by the territories of La Pampa and Neuquen, and W. by the republic of Chile. Area, 56,592 sq. m.; pop. (1893), 116,136; (1904, estimate), 130,780. The Andes are the chief boundary, and a considerable part of the territory is covered by the great Cordillera, its foothills and flanking ranges. The eastern part is an arid, sandy, level plain, with extensive saline basins, having no vegetation other than coarse grasses and thickets of low, spiny mimosas and "chara" (*Guiriza decorticans*). The fertile, populated districts of the province border on the Cordillera, particularly in the north where numerous streams from the snow-clad summits supply water for irrigation. The secondary ranges in this part of Mendoza are the Sierra de los Paramillos, which encloses the Usppallata Valley, and the Sierra del Tunuyán, which encloses a number of populous valleys drained by the Tunuyán river and its tributaries. One of the largest of these is the Yuco Valley. Farther south the country becomes more arid and sparsely populated, and unsubdued tribes of Indians for a long time prevented its exploration. In this region the Sierra de Payén and Sierra del Nevado (otherwise known as the Sierra Quero Matro Pellan) extend in a north-easterly direction. With the exception of the Rio Grande in the south-west part of the province, which forms the principal source of the Colorado, all the rivers of the province flow easterly and southerly into the great saline depression of western Argentina, which is the most arid region of the province. San Luis and La Pampa. The Andean streams rise in the higher snow-clad elevations, but their waters become impregnated with saline matter soon after reaching the plains, and are eventually lost in the saline marshes and lagoons of southern Mendoza and La Pampa. These Andean rivers are the Mendoza, Tunuyán, Diamante and Atuel, with their numerous tributaries, all of which discharge into the sluggish river which flows from the Huanacache lagoons, on the San Juan frontier, southward to the marshes and lagoons of La Pampa. The upper part of this branchy, swampy stream is called the Desaguadero, and the lower the Salado. It forms the eastern boundary line of the province down to the 36th parallel. With the exception of the elevated districts of the Andes, the climate of Mendoza is hot and dry. On the plains the rainfall is insignificant, but on the slopes of the Cordillera rains are frequent and winter cold is severe. Agriculture is the principal occupation where irrigation can be used, the province having a great reputation for its raisins and wines. Alfaífa is an important product, being grown for fattening the cattle driven through the province to the Chilean markets. The mineral resources of the province are said to be good, but includes little of the province. Mendoza is found in the vicinity of San Rafael, the Diamante river, and it is claimed that coal exists in the same region. Although Mendoza was settled by Spanish colonists from Chile as far back as 1550, its development has been hindered by its isolated position. This isolation was broken in 1884, by the completion of the Argentine Great Western railway to the provincial capital. Since then a railway has been built northward to San Juan, and another line was in 1908 under construction through the Andes to connect with the Chilean railway system. In addition to Mendoza, the capital of the province, the principal towns (hardly more than villages) are Guaymallén, Malpú, San Martin, Luján and San Rafael. The provinces of Mendoza, San Juan and San Luis, which were settled from Chile and were for a long time governed from Santiago, were at first called the province of Cuyo, and are still spoken of as the "Cuyo provinces."

**MENDOZA**, a city of Argentina, capital of Mendoza province, 632 m. by rail W.N.W. of Buenos Aires. Pop. (1904, estimate), 32,000. It stands on a plain near the foot of a secondary Andean range called the Sierra de los Paramillos, at an elevation of 2320 ft. The surrounding district is arid, but has been irrigated and is covered with gardens, orchards and cultivated fields. The city is about 15 m. N. of the Mendoza, or Luján river, whose waters are utilized for irrigation and for the requirements of the city by means of a channel which leaves the main river a little above the town of Luján and runs to the Tulumaya river and the lagoons of Huancací. This channel is called El Zanjón, and is believed to have been opened by Guaymallén, the chief of the Guarapiés who inhabited this district at the time the Spaniards arrived. This region is more probably natural. The city is laid out in a broad manner with broad well-paved streets and numerous public squares. The Zanjón and another stream called the Guaymallén traverse the city, and the principal streets have water flowing through them and are shaded by poplars. Because of earthquake risks, the public buildings are neither costly nor imposing. The private residences are commonly of one story, built with wooden frames filled in with adobe. The climate is hot, dry and enervating, notwithstanding the elevation and the proximity of the Andes. The surrounding districts produce fruit, vegetables, alfalfa and wine. The vineyard industry is prominent, and raisins and wine are exported. The position on the main route across the Andes into Chile, by way of the Usppallata or Cumbre pass (highest point 12,870 ft.), has given the city commercial importance. It has railway connexion with the principal cities of the republic, including the ports of Rosario, Buenos Aires and Bahía Blanca, and also with the capital of San Juan.

Mendoza was founded by Captain Pedro del Castillo, who had been sent from Santiago across the Andes in 1550 by García Hurtado de Mendoza, the governor of Chile, to conquer and annex the territory extending N.E. to Tucuman. The city was not established until after Mendoza died in 1552. The province was transferred to the newly created viceroyalty of La Plata. It was the headquarters of General San Martin while he was organizing an army for the liberation of Chile, and greatly assisted him with men and money. Under republican administration Mendoza suffered much from revolutions. Moreover, on the 20th of March 1861, the city was destroyed by an earthquake and a fire which followed. Not a building was left standing, and the loss of life was estimated at 25,000 to 26,000. The French geologist Bravard, who had predicted the catastrophe, was one of the victims. The ruins in the streets, together with some species of fruit-trees, were first planted in Mendoza by a Spaniard, Juan Cobos, in 1809, who thus became one of its greatest benefactors.

**MENEDÈMUS**, Greek philosopher, and founder of the Eretrian school of thought, was born at Eretria about 350 and died between 278 and 275 B.C. Though of noble birth, he worked as builder and tentmaker until he was sent with a military expedition to Megara, where, according to Diogenes Laertius, he heard Plato and resolved to devote himself to philosophy. It is more likely that he heard one of Plato's followers, in much as Plato died when he was only four years old, if the above dates are correct. At Megara he formed a life-long friendship with Asclepiades, with whom he tooled in the night that he might study philosophy by day. He was subsequently a pupil first of Stilpo and then of Phædo of Ellis, whose school he transferred to Eretria, by which name it was afterwards known. In addition to his philosophical work, he took a leading part in the political affairs of his city from the time of the Diadochi until his death, and obtained a remission of the tribute to Demetrius. His friendship with Antigonus Gonatas seems to have roused suspicion as to his loyalty, and he sought safety first in the temple of Amphiaraurus at Oropus, and later with Antigonus, at whose court he is said to have died of grief. Other accounts say that he starved himself to death on failing to induce Antigonus to free his native city. His philosophical views are known only in part. Athenaeus quotes Epicrates as stating that he was a Platonist, but other accounts credit
him with having preferred Stilpo to Plato. Diogenes Laërtius (ii. 134 and 135) says that he declined to identify the Good with the Useful, and that he denied the value of the negative proposition on the ground that affirmation alone can express truth. He probably meant to imply that qualities have no existence apart from knowledge which articles of ethics we learn from Plutarch (De virt. mor. 2) and from Cicero (Acad. ii. 42) that he regarded Virtue as one, by whatever name it be called, and that it is intellectual. Cicero's evidence is the less valuable in that he always assumed that Menedemus was a follower of the Megarians. Diogenes says that he left no writings, and that the Eretrian school disappeared after a short and unobtrusive existence.

Beside the ancient sources quoted above, see H. Mallet, Histoire de la littérature grecque et latine, école d'Erétrie (1845). Also the articles MEGARIAN SCHOOL; PHAEDO; STILO.

MENELAUS, in Greek legend, son of Atreus (or Pleisthenes), king of Sparta, brother of Agamemnon and husband of Helen. He was one of the Greeks who entered Troy concealed in the wooden horse (Virgil, Aeneid, ii. 264) and recovered his wife at the sack of the city. On the voyage homewards his fleet was scattered off Cape Malea by a storm, which drove him to Egypt. After eight years' wandering in the east, he landed on the island of Pharos, where Proteus revealed to him the means of appeasing the gods and securing his return. He reached Sparta on the day on which Orestes was holding the funeral feast over Aegisthus and Clytemnestra. After a long and happy life in Lacedaemon, Menelaus, as the son-in-law of Zeus, did not die but was translated to Elysium (Homer, Odyssey, iii. iv.). His grave and that of Helen were shown at Therapnae, where he was worshipped as a god (Pausanias ii. 19, 9). He was represented in works of art as carrying off the body of the dead Patroclus or lifting up his hand to slay Helen.

MENELEK II. (SAHALA MARLEM), emperor of Abyssinia, officially negus negus (king of kings) of Ethiopia (1844— ), son of Haeli Melichoth, king of Shoa, was born in 1844, and claimed to be a direct descendant of Solomon by the queen of Sheba. On the death of his father in 1855 he was kept a prisoner at Gondar by Kassai, the governor, who had seized the throne under the title of Theodore III. But having succeeded in effecting his escape he was acknowledged king of Shoa, and at once attacked the usurper. These campaigns were unsuccessful, and he turned his arms to the west, east and south, and annexed much territory to his kingdom, still, however, maintaining his divine right to the crown of Ethiopia. After the death of Theodore in 1888 he continued to struggle against his successor, the emperor Ras Tafari (better known as King John of Abyssinia). Being again unsuccessful, he resolved to await a more propitious occasion; so, acknowledging the supremacy of Johannes, in 1886 he married his daughter Zeclita (b. 1876) to the emperor's son, the Ras Area; he was thereupon declared heir to the empire, and on his side acknowledged the Ras Area as his successor. Ras Area died in May 1888, and the emperor Johannes was killed in a war against the dervishes at the battle of Gallasbat (Matema) on the 10th of March 1889. The succession now lay between the late emperor's natural son, Ras Abba Selassie, and Menelik, whom the latter, by a large majority on the 4th of November, and consecrated shortly afterwards. Menelek had married in 1883 Taltu (b. 1854) a princess of Tigré, a lady who had been married four times previously and who exercised considerable influence. Menelek's clemency to Mangasha, whom he compelled to submit and then made viceroy of Tigré, was ill repaid by a long series of revolts. In 1889, at the time when he was claiming the throne against Mangasha, Menelek signed at Uchiali a treaty with Italy acknowledging Italian claims to the Asmara district. Finding, however, that according to the Italian view of one of its articles the treaty placed his empire under Italian domination, Menelek denounced it, and after defeating the Italians at Amba-Alagi, he compelled them to capitulate at Adowa in February 1896, and a treaty was signed recognizing the absolute independence of Abyssinia. His French sympathies were shown in a reported official offer of treasure towards payment of the indemnity at the close of the Franco-Prussian War, and in February 1897 he concluded a commercial treaty with France on very favourable terms. He also gave assistance to French officers who sought to reach the upper Nile from Abyssinia, there to join forces with the Marchand led only to study. Menelek became firm to the Nilewards. A British mission under Sir Rennell Rodd in May 1897, however, was cordially received, and Menelek agreed to a settlement of the Somali boundaries, to keep open to British commerce the caravan route between Zalla and Harrar, and to prevent the transit of munitions of war to the Mahdists, whom he proclaimed enemies of Abyssinia. In the following year the Sudan was reconquered by an Anglo-Egyptian army and thereaftercordial relations between Menelek and the British authorities were established. In 1889 and subsequent years, Menelek sent forces to co-operate with the British troops engaged against the Somali mullah, Mohammed Abdullah. Menelek had in 1898 crushed a rebellion by Ras Mangasha (who died in 1906) and he directed his efforts henceforth to the consolidation of his authority, and in a certain degree, to the opening up of his country to western civilization. He had granted in 1894 a concession for the building of a railway to his capital from the French port of Jibuti, but, alarmed by a claim made by France in 1902 to the control of the line in Abyssinian territory, he stopped for four years the extension of the railway beyond Dire Dawa. When in 1906 France, Great Britain and Italy came to an agreement on the subject, Menelek officially reiterated his full sovereign rights over the whole of his empire. In May 1909 the emperor's grandson Lij Yassu, or Jassu, then a lad of thirteen, was married to Romanie (b. 1902), granddaughter of the negus Johannes. Two days later Yassu was publicly proclaimed at Adis Ababa as Menelek's successor. At that time the emperor was seriously ill and as his health continued, a council of regency—from which the emperor was excluded—was formed in March 1910. (See also ABBYSSINIA.)

MENENDEZ Y PELAYO, MARCELINO (1856— ), Spanish scholar and critic, was born at Santander on the 3rd of November 1856. In 1871-1872 he studied under Milà y Fontanals at the university of Barcelona, whence he proceeded to the central university of Madrid. His academic successes had never been surpassed; a special law was passed by the Cortes to enable him to become a professor at the age of twenty-two, and three years later he was elected a member of the Spanish Academy. But before this date (1882) he was well known throughout Spain. His first volume, Estudios críticos sobre escritores modernistas (1876), had attracted little notice, and his scholarly Horacio en su época (1885), better known as El empirismo (better known as El empirismo), written through his Ciencia española (1878), a collection of polemical essays defending the national tradition against the attacks of political and religious reformers. The unending orthodoxy of this work is, if possible, still more pronounced in the Historia de los heterodoxos españoles (1886-1886), and the writer was hailed as the champion of the ultramontane party. His lectures (1881) on Calderón established his reputation as a literary critic; and his work as an historian of Spanish literature was continued in his Historia de las ideas estéticas en España (1881-1891), his Teoría de la novela, 1890-1903, of Lope de Vega, his Antología de poetas líricos castellanos (1890-1900), and his Orígenes de la novela (1905).

MENENIUS LANATUS, AGrippa, Roman patrician and statesman, consul 503 b.C. On the occasion of the first secession of the people to the Sacred Mount, Agrippa, who was known to be a man of moderate views, was one of the commissioners empowered by the senate to treat with the seceders. On this occasion he recited the well-known fable of the belly and the members.

Livy ii. 16, 32, 33; Dion. Hal. v. 44-47; vi. 49-88; 96; Val. Max. iv. 4, 2.

MENES, the name of the founder of the 1st Dynasty of historical kings of Egypt. He appears at the head of the lists not only in Herodotus and Manetho, but also in the native Turin Papyrus of Kings and the lists of Abydos, while the list
MENGS—MENIN

of Sakkarah begins with the sixth king of the 1st Dynasty, a fact which may throw some doubt on the supposed foundation of Memphis by Menes. Until recently he was looked upon as semi-mythical, but the discovery of the tombs of many kings of the 1st Dynasty including probably that of Menes himself, as well as an abode of remains of still earlier date, has given him a personality. He was probably ruler of Upper Egypt and conquered the separate kingdom of Lower Egypt.

See EGYPT: K. Sethe, "Menes und die Grundung von Memphis," in his Untersuchungen zur Geschichte und Alterthumskunde Aegyptens, iii. 121. (F. L. G.)

MENGS, ANTONY RAPHAEL (1728–1779), German painter, was born in 1728 at Aussig in Bohemia, but his father, Ismael Mengs, a Danish painter, established himself finally at Dresden, whence in 1741 he took his son to Rome. The appointment of Mengs in 1749 as first painter to the elector of Saxony did not prevent his spending much time in Rome, where he had married in 1748, and abjured the Protestant faith, and where he became in 1754 director of the Vatican school of painting, nor did this hinder him on two occasions from obeying the call of Charles III. of Spain to Madrid. There Mengs produced some of his best work, and specially the ceiling of the banqueting-hall, the subject of which was the Triumph of Trajan and the Temple of Glory. After the completion of this work in 1777, Mengs returned to Rome, and there he died, two years later, in poor circumstances, leaving twenty children, seven of whom were pensioned by the king of Spain. Besides numerous paintings in oils and in fresco executed at Dresden, Persépolis, and Andromeda at St. Petersburg, and the ceiling of the Villa Alboni must be mentioned among his chief works. In England, the duke of Northumberland possesses a Holy Family, and the colleges of All Souls and Magdalen, at Oxford, have altar-pieces by his hand. In his writings, in Spanish, Italian and German, Mengs has put forth his eclectic theory of art, which treats of perfection as attainable by a well-schemed combination of diverse excellences—Greek design, with the expression of Raphael, the chiaroscuro of Correggio, and the colour of Titian.

His intimacy with Winckelmann, who constantly wrote in his dictation—has enhanced his historical importance, for he formed no scholars, and the critic must now concur in Goethe's judgment of Mengs in Winckelmann and sein Jahrhundert; he must deplore that so much learning should have been allied to a total want of initiative and poverty of invention, and embodied with a strained and artificial mannerism.

See Opere di Antonio Raffaello Mengs (Parma, 1780); Mengs Werke, übersetzt v. G. F. Frange (1786); Zeitschrift für bildende Kunst, di Mengs (Milan, 1780); Woermann, Ismael und Raphael Mengs (Leipzig, 1893).

MENGTSZE, a city in the S.E. of the province of Yunnan, China. Pop. about 12,000. It was selected by the French convention of 1886 as the seat of the overland trade between Tongking and Yunnan, and opened two years later. It is beautifully situated in the centre of a valley basin on a plateau 3500 ft. above sea-level. The country round is fertile and well cultivated, and the place must have been one of considerable wealth before the Taiping rebellion, as the ruins of many fine temples attest. A considerable overland trade has sprung up since the opening of Mengtsze. Of the import trade Hong-Kong supplied 86%, and of the export trade 70%, Cochín-China, Tongking and Yunnan claiming the remainder. Tin (68%) and opium (27.8%) are the principal exports, and textiles (71%), mostly cottons, and tobacco (4%) the chief imports. On the Tongking side this trade follows the Red River route as far as Manhao, which is distant from Mengtsze about 40 m., though the navigation of the river is difficult. From Manhao the transit is by coolies or pack animals. Concessions have been obtained by the French government to build a line of railway from the Tongking frontier at the town of Lackay via Mengtsze to Yunnan-fu. The climate is equable and healthy.

MENHADEN, economically one of the most important fishes of the United States, known by a great number of local names, "menhaden" and "mossbunker" being those most generally in use. The Indians and white settlers used it as a manure, and the name is Narragansett for "fertilizer." Its scientific name is Clupea (or Allos) menhaden and Brevoortia tyrannus. It is allied to the European species of shad and pilchard, and, like the latter, approaches the coast in immense shoals, which are less numerous throughout the year in some part of the littoral waters between Mainz and Florid, the northern shoals reaching into deeper water or to more southern latitudes with the approach of cold weather. The average size of the menhaden is about 12 in. It is too bony and oily for a table-fish, but is used as bait for cod and mackerel. A large fleet is engaged in the fishery; and a great number of factories extract the oil for tanning and currying, and for adulterating other more expensive oile, and manufacture the refuse into a valuable guano.

MENIAL, which that belongs to household or domestic service, hence, particularly, a domestic servant. The idea of such service being derogatory having the term since contempt. The word is derived from an obsolete meenie or minxy, the company of household servants or retainers; a Scottish form is menzie. The origin is to be found in the O.Fr. menzie, popular Lat. mansionata, from mansion, from which comes Fr. maison, house.

MÉNIER, EMILE JUSTIN (1826–1881), French manufacturer and politician, was born at Paris in 1826. In 1853, on the death of his father, Antoine Brutus Ménier, he became proprietor of a large drug factory, founded in 1815 by the latter at Saint Denis, Paris, and in 1839 at Noisiel-sur-Marne. Antoine Brutus Ménier had also manufactured chocolate in a small way, but he purchased cocoa-growing estates in Nicaragua and beet-fields in France, erected a sugar-mill, and equipped himself in other ways for the production of chocolate on a large scale. In 1864 he sold his interest in the drug-manufacturing business, and thenceforth confined himself to chocolate, building up an immense trade. Ménier was a keen politician, and from 1876 till his death had a seat in the French Chamber, his general views being strongly Republican, while he consistently opposed protection. He was the author on fiscal and economic questions, notably L'Impôt sur le capital (1872), La Réforme fiscale (1872), Économie rurale (1875), L'Avenir économique (1875–1878), Atlas de la production de la richesse (1878). He died at Noisiel-sur-Marne in 1884, his sons succeeding to the business.

MÉNÈRIÈRE'S DISEASE, a form of auditory vertigo, first described by a French physician, Emile Antoine Ménèrie, in 1861. It usually attacks persons of middle age whose hearing has been previously normal. A. Politzer gives the following as the principal causes: intense heat and exposure to the sun, rheumatism, insomnia, and exposure to infection. The disease presents itself in various forms, but the most usual is the appolectic form, due to haemorrhage into the labyrinth, followed by more or less complete deafness in either or both ears. The attack usually sets in with dizziness, noises in the ears, nausea, vomiting and staggering gait, and the patient may suddenly fall down with loss of consciousness. The seizures are usually paroxysmal, occurring at irregular intervals of days or weeks. Between the attacks the equilibrium may be disturbed, there being marked nystagmus and unsteadiness of gait. The attacks of vertigo tend to become less frequent and may entirely pass away, but the deafness may remain permanent. The treatment is directed towards relieving the troublesome head symptoms by the application of cold compresses. The drug that has proved most serviceable in diminishing the dizziness is potassium iodide, administered daily for at least a month. Politzer considers that the attacks may be averted by producing rarefaction of the air in the external meatus of the ear by means of a specially devised aspirating tube.

MENIN (Flemish Meenen), a town in Belgium of the province of West Flanders situated on the Lys 7 m. S. of Courtrai. Pop. (1904), 19,377. It manufactures linen and flannel, and in the neighbourhood are extensive tobacco plantations. It was first

MENINGITIS

Fortified in 1528, and in 1689 Vauban made it one of the strongest places on the French frontier, but the fortifications were razed in 1748 by the treaty of Aix-la-Chapelle.

MENINGITIS (from Gr. μηνίγη, a membrane), a term in medicine applied to inflammation affecting the membranes of the brain (cerebral meningitis) or spinal cord (spinal meningitis) or both.

Cerebral meningitis (or Acute Hydrocephalus) is a disease due to inflammation of the meninges of the brain produced by the presence of a tubercle bacillus. This disease is most common in children under ten years of age, but may affect adults. The tuberculous constitution is an important factor in this malady. In numerous cases it is manifestly connected with bad hygienic conditions, with insufficient or improper feeding, or with over exercise of the mental powers, all of which will doubtless more readily exert their influence where an inherited liability exists, and the same may be said regarding its occasional occurrence as one of the after consequences of certain of the diseases of childhood, especially measles and whooping-cough.

There are certain typical features characterizing the disease in each of its stages. The premonitory symptoms are mostly such as are found in the stomach, and are attributable to depression of the digestive function. These symptoms are often observed for a considerable time before the characteristic phenomena of the disease appear. The patient, if a child, becomes listless and easily fatigued, loses appetite, and is ready to cry. Headache is a characteristic symptom, and the child becomes unusually irritable. These symptoms may persist during many weeks; but on the other hand such premonitory indications may be entirely wanting, and the disease be developed to all its extremes.

The onset is in most instances marked by the occurrence of vomiting, often severe, but sometimes only slight, and there is in general obstinate constipation. In not a few cases the first symptoms are convulsions, which, however, may in this early stage subside, and remain absent, or reappear at a later period. Headache is one of the most constant of the earlier symptoms, and is generally intense. It is associated with speech disorder of the patient to scream, with a peculiar and characteristic cry. There is great intolerance of light and sound, and general nervous sensitivity.

Fever is present to a greater or less extent; the temperature ranging from 100° to 103°; yet the pulse is not quickened in proportion, being on the contrary rather slow, but exhibiting a tendency to irregularity, and liable to become rapid on slight exertion. If breathing, too, is somewhat irregular. Symptoms of this character, constituting the stage of excitement, continue for a period varying from one to two weeks, when they are succeeded by the stage of depression. There is now a marked change in the symptoms, which is apt to lead to the belief that a favourable turn has taken place. The patient becomes quieter and inclines to sleep, but it will be found on careful watching that this is not the case. The condition of the patient now is one in which the child has sunk. The vomiting has ceased, and there is less fever; the pulse is slower, and shows a still greater tendency to irregularity than before, while the breathing is of markedly undulating character. The tongue is now dry at one place, long drawn out and sinking away at another. There is manifestly little suffering, although the peculiar cry may still be uttered, and the patient lies prostrate, occasionally rolling the head uneasily upon the pillow, or picking at the bed-clothes or at his face with his fingers. He does not ask for food, but readily swallows what is offered. The countenance is pale, but is apt to flush up suddenly for a time. The eyes present important alterations, the pupil being dilated or unequal, and scarcely responding to light. There may be double vision, or partial or complete blindness. Squinting is common in these cases. For in the stage of excitement the eyes of the patient are probably exercising a paralytic influence upon the cranial nerves, and in this cutting off of the nerves a sort of paralysis of the visual system may be due to paralysis of the part, and one or more limbs may be likewise paralysed.

To this succeeds the third or final stage, in which certain of the former symptoms recur, while others become intensified. There is generally a return of the fever, the temperature rising very high. The pulse becomes feeble, rapid, and exceedingly irregular, as is also the case with the breathing. Coma is profound, but yet the patient may still be got up for a time. It is not so readily as before. Convulsions are apt to occur, while paraesthesia, more or less extensive, affects portions of the body or groups of muscles. Faintness is now rare, and with it there are comparatively complete blindness and often deafness. In this condition the patient's strength undergoes rapid decline, and the body becomes markedly emaciated. Death takes place either suddenly in a fit, or as the result of insidious exhaustion. Shortly before death it is not uncommon for the patient, who, it may be for many days previously, lay in a state of profound stupor, to awake up, ask for food, call for assistance, and talk profusely. The breathing is somewhat, but in general death takes place within three weeks from the onset of the symptoms. The disease may be said to almost invariably fatal, yet cases presenting all the principal symptoms occasionally recover.

It may be done in the way of prevention of this disease, and, in its earlier stages, even in the way of cure. It is most important in families where the history indicates a tuberculous or scrofulous tendency, and where some child has already recovered. With this view wholesome food, warm clothing, cleanliness, regularity, and the avoidance of over-exertion, physical and mental, are of the utmost consequence.

There is a peculiar type of meningitis occasionally mentioned in the symptoms when they arise. The maintenance of the patient's strength by nourishment and the use of sedatives to compose the nervous system are the measures most likely to be attended with success. Where the portion of potash, the medicinal agent of most value for this purpose. Should convulsions occur, they are best treated by chloral or chloroform.

In what is known as suppurative, or simple acute meningitis (non-tubercular), the disease arises from various causes, and the symptoms are similar to those described above.

In posterior-basic meningitis, inflammation of the membranes investing the posterior basic spinal cord, the chief symptoms are fever, with severe pain in the back or loins shooting downwards into the limbs (which are the seat of frequent painful involuntary startings), accompanied with a feeling of tightness round the body.

The local symptoms bear reference to the portion of the cord the membranes of which are involved. The inflammation located in the cervical portion the muscles of the arms and chest are spasmodically contracted, and there may be difficulty of swallowing or breathing, or embarrassment heart's action, while when the disease is seated in the lower portion, the lower limbs and the bladder are the parts affected in this way. At first there is excited sensibility (hyperesthesia) in the parts of the surface of the body in relation with the portion of cord affected. As this subsides a sense of numbness may be experienced, with partial loss of power in the affected muscles, and also partial anaesthesia. These various phenomena may entirely pass away, and the patient after some weeks or months recover; or, on the other hand, may increase, and end in permanent paralysis.

Some observers regard these forms as sporadic cases of cerebrospinal fever; and Still, William Hunter and George Nuttall have isolated an organism similar to the diplococcus intracellularis, while Henry Koplik in New York found cases of typical posterior-basic meningitis due to the diplococcus intracellularis.

The treatment is directed to allaying the pain and inflammatory action by opiates; the greatest care is taken on the part of many physicians.

The patient should have perfect rest in the recumbent, or better still in the prone, pose. Cold applications to the spine may be given in proportion to the function of the bladder and bowels, and to the condition of the skin with the view of preventing bedsores, is all-important.

Cerebro-spinal fever or epidemic cerebro-spinal meningitis, popularly called "spotted fever," is an infectious disease occurring sporadically or in epidemics, and due to the diplococcus intracellularis discovered by Vieussens in 1887. This disease was not recognized until the 19th century. It was first described at Geneva in 1805 and small outbreaks followed in Paris (1814), Metz and Genoa (1818), and Westphalia (1822), but in the United States there was a widespread epidemic, including New England and spreading as far as Kentucky and Ohio. Fresh outbreaks in Europe took place between 1837 and 1850. In 1837 it prevailed in the south of France chiefly amongst troops in garrison, and fresh outbreaks continued throughout France in 1836 with epidemics in Algiers, Italy and Sicily. In Great Britain it first showed itself in the Irish workhouses in 1846, where it was known as "the black death" or "malignant purpuric fever." After 1866 except for sporadic cases it disappeared from Great Britain, but small outbreaks took place in 1885 to 1900 in Dublin. In 1905 there was an extensive epidemic in New York, followed by an outbreak in Scotland in 1906, and in Scotland and Ireland in 1907-1908. The registrar-general's returns for 1907 give 1018 deaths in Scotland due to the disease, of which 711 were at Glasgow and 148 at Edinburgh. In the same year Belfast was visited by a severe epidemic, 495 deaths out of the total death-rate of 631 taking place in that district.
The mode of infection is obscure, but the organism is thought to gain access to the circulation through the mucous membrane of the nose and conjunctiva, as the organism has been isolated from the mucous membrane of the nose and conjunctiva of some of those suffering from the disease but from healthy persons who have been in contact with cases. Cerebro-spinal fever has an undoubted tendency to follow bad sanitary conditions and to prevail in damp, sunless houses, and those who are too tired and overworked may usually take place in the spring of the year. The victims are mostly children and young adults, and Koplik states that few recoveries take place in children under two years of age.

MENIPPIUS, of Gadara in Coele-Syria, Greek cynic and satirist, lived during the 3rd century B.C. According to Diogenes Lærrius (vi. 8) he was originally a slave, amassed a fortune as a money-lender, lost it, and committed suicide through grief. His works (written in a mixture of prose and verse) are all lost. He discussed serious subjects in a spirit of raillery, and especially delighted in attacking the Epicureans and Stoics. His writings exercised considerable influence upon later literature. One of the dialogues attributed to Lucian, his avowed imitator, who frequently mentions him, is called Menippus. But this dialogue is regarded with suspicion, and since the sub-title ("The Oracle of the Menippus") resembles that of a lost dialogue written by Diogenes Lærrius, it has been suggested that it really is the work of Menippius himself, or at any rate imitated from his Néaoua by the author, whether Lucian or another. It is well known that the Menippéan satires of M. Terentius Varro, the fragments of which give an idea of this kind of composition, were called after Menippius of Gadara (see Teuffel-Schwabe, Hist. of Roman Literature, § 165, 3).

BIBLIOGRAPHY.—F. Ley, De vita scriptorum Menippi et Luciani (1913); R. Hahn, Lucian (1929); R. Hahn, Syllogeorum graecorum reliquiae (1885), with an account of Menippius and similar writers. Menippius found an imitator in later times in Justus Lipsius, author of a Satyrus menippæae (1657) with a preface in which the author speaks of his principal debt to Diogenes Lærrius, and in the writings of Thomas Libavius (1624), a writer of note, and in the dialogues of Lucian and Diogenes Lærrius; and in the authors of the famous Satyri Menippici (1903; latest editions by C. Marx, Paris, 1888; J. Frank, Oppeln, 1884), written against the Holy League during the reign of Henri IV.

MENIUS, JUSTUS (1400–1558), Lutheran theologian, whose name is Latinized from Jost or Just (i.e. Jodocus) Menig, was born at Fulda, of poor but respectable parents, on the 13th of December 1400. Entering the university of Erfurt in 1424, he took the bachelor's degree in 1454, the master's in 1458. At this time, in association with the keen humanitarian Conrad Mutian, Crocus Rubenous and Eoban Hess, he was of sceptical tendency; moving to Wittenberg in 1519, he became evangelical under the teaching of Melanchthon and the preaching of Luther. After travel in Italy (1521–1522) he was appointed (1522) town's preacher at Wittenberg, but was soon transferred to the charge of Mühlberg, under Erfurt. Here he published his commentary on Acts (1524) and married. He resigned his charge (1529) and opened a school at Erfurt, but the town council insisted on his resigning his post on pain of excommunication, and appointing his preceptor in his place; the new preceptor was Thomas Kermauer, who had just been appointed by the Lutheran church in 1529. After a short period at Erfurt, he went to Erfurt, and worked in conjunction with Luther's friend, John Lange, and was opposed by the Franciscans under Conrad Kling. Hence he left for Gotua (1528), resumed teaching, and enjoyed the friendship of Friedrich Myconius. Duke John of Saxony had placed him on the commission for church visitation in Thuringia, and in 1529 appointed him pastor and superintendent at Eisenach, where for eighteen years he administered church affairs with tact, and fostered the spread of education. In 1550 he brought out his Oeconomia christiana (a treatise in German, on the right ordering of a Christian household) with a dedication to the duchess Sybyl of Saxony and a preface by Luther. His tractate, written in concert with Myconius, controversy Der Wiedertümer Lehre und Geheimmiss (1550) was also prefixed by Luther. The reversion to the Roman communion of his old friend Croesus led to his ordination Responso amici (1532, anon.) to the Apologia (1531) of Croesus. He took his part in the theological disputations of the time, at Marburg (1529), the Concordia at Wittenberg (1536), the Convention at Schmalkalden (1537), the discussions at Hagana and Worms (1540). His tractate (1543) against the permission of bigamy in the case of Philip of Hesse was not allowed to be printed, (his manuscript is in the Heidelberg university library). In 1542 he removed to Mühlhausen, being appointed by Duke Henry of Saxony for the ordering of the church there. On the death of Myconius (1546) he was appointed with the oversight of Gotua, in addition to that of Eisenach; to Gotua he returned in 1547. The remainder of his life was not happy. He was against the Leipzig Interim (1548) with its compromise on some Catholic usages, and was involved in controversies and quarrels; with Georgus Merula, against whom he maintained the need of exorcism in
baptism; with Osianter's adherents in the matter of justification; with his colleague, Nicholas von Amstorf, to whom he had resigned the Eisenach superintendency; with Flacius Illyricus, and others. He lost favour with Duke John Frederick of Saxony, fell into bad health, was deposed (1555) from his offices, and was duly to obey his all lawful command, and retired to the college at Eisenach (1556). He died at Leipzig on the 11th of August 1558. He was twice married, and had several sons, of whom Eusebius held a chair of philosophy at Wittenberg, and married Melanchthon's grand-daughter, Anna Sabinus. Schmidt gives a full bibliography of the numerous writings of Menius, who translated several of Luther's biblical commentaries into German. His Oeconomia was reprinted in 1855.

MENKEN, ADAH ISAACS (1835–1868). American actress, was born in New Orleans, the daughter of a Spanish Jew, her name being Dolores Adios Fuertes. Left in poverty at the age of thirteen, she made her first appearance as a dancer in her native city. She had a great success there and in other southern cities, including Havana, and she afterwards aspired to act in serious parts. In 1856 she married John Isaacs Menken, translated Adios to Adah, and thus took the name she thereafter bore through various matrimonial ventures. In 1864 she appeared at Astley's in London as Mazeppa, a performance of an actress type suited to her finition, and after the treaty of peace with France she became intimate with many literary men—Swinburne, Charles Reade, Dickens (to whom she dedicated in 1868 a volume of verse, Infidelia), Gautier and Dumas the elder. Paris saw her for a hundred nights in Les Pirates de la Savane, and she also played in Vienna and again in London. She died in Paris on the 10th of August 1868.

MENNONITES, a body of religious men who take their name from Menno Simons (see below), the most valued exponent of their principles. They maintain a form of Christianity which, discarding the sacerdotal idea, owns no authority outside the Bible and the enlightened conscience. Limits baptism to the believer, and lays stress on those precepts which vindicate the sanctity of human life and of a man's word. The place of origin of the views afterwards called Mennonite (see BAPTISTS) was Zürich, where in 1523 a small community left the state church and (from Jan. 18, 1525) adopted the tenet of believers' baptism. Unlike other Reformers, they denied at once the Christian character of the existing church and of the civil authority, though, in common with the first Christians, it was the dispensation not the institution of an ecclesiastical creation. By Protestants as much as by Catholics this position was not unnaturally regarded as subversive of the established foundations of society. Hence the bitter persecutions which, when the safety of toleration was not imagined, made martyrs of these humble folk, who simply wished to cultivate the religious life apart from the world. There was something in this idea which answered to that medieval conception of separation from the world which had leavened all middle-class society in Europe; and the revolt from Rome had prepared many minds to an idea of separation in the cause of the pursuit of holiness in a society pledged to primitive discipline. Hence the new teaching and praxis spread rapidly from Switzerland to Germany, Holland and France. While the horrors of the Münster fanaticism, which culminated in 1534, made Anabaptism a byword, and increased the severity of a persecution directed against all Baptists indiscriminately, the reaction against the fatal errors of the Münster experiment increased also the adherents of communities which discarded the sword; thus Menno was brought into their ranks. Each community was independent, united with others only by the bond of love. There was no hierarchy (as with the Quakers), but "exhorters," chosen by the members, among them "elders" for administering baptism and the Lord's Supper; an arrangement so readily renewed that the sure way of putting down such a body was the execution of all its constituents, often by drowning, an appropriate end, according to Zwingli's quip. The remnant of the Swiss Mennonites (not tolerated till 1716) broke in 1620 into two parties, the Uplanders (or Amish, from their leader Jacob Amer) holding against the Lowlanders that excommunication of husband or wife dissolved marriage, and that razors and butts were unlawful. In Holland in Canada, 18,000 in Germany have always been numerous. An offshoot from them at Rijnburch in 1619, founded by the four brothers, farmers, Van der Kode, and named Collegianten from their meetings, termed collegia (thus, as not churches, escaping the penal laws), has been compared to the Plymouth Brethren, but differed in so far as they required no conformity of religious opinion, and recognized no office of teacher. With them, as Martineau notes, Spinoza had "an intense fellow-feeling." Later, the exiled Socinians from Poland (1660) were in many cases received into membership. There had previously been overtures, more than for union, with Menonites on the part of Polish Socinians, who agreed with them in the rejection of oaths, the refusal to take human life, the consequent abstinence from military service and magisterial office, and in the Biblical basis of doctrine; differences of doctrinal interpretation precluded any fusion. In Holland the Mennonites were exempted from military service in 1575, from oath-taking in 1585, from public office in 1617. In Zeeland exemption from military service and oaths was granted in 1577; afterwards, as in Friesland, a heavy poll tax was the price of exemption from military service; but since 1795 they have enjoyed a legal exemption. The Mennonites of the Voges were exempted from military service in 1793, an exemption confirmed by Napoleon, who employed them in hospital service on his campaigns. That he did not exempt the Dutch Mennonites is due to the fact that "they had ceased to present a united front of resistance to military claims" (Martineau); in fact they sent a large band of volunteers to Waterloo (Barclay). While in Germany the Mennonites exist in considerable numbers, more important are the German Mennonite colonies in southern Russia, brought there in 1786 by Baron von Czerny, the emanation of complete religious liberty, from the hardships imposed by Prussian military law. These colonies have sent many emigrants to America, where their oldest community was settled (1863) at Germantown, Pennsylvania. Their settlement in Canada dates from 1786. Among the American Mennonites there are three sections, and a progressive party, known as New School Mennonites.

S. Cramer gives (1903) the following statistics: in all, some 250,000 members, of whom over 80,000 are in the United States, 70,000 in Holland, and 4,000 in Denmark, and the rest scattered in Canada, 400 in Switzerland, 800 in France, and the same number in Poland and Galicia.

MENNO SIMONS (1492–1555), religious leader, was born in 1492 at Wittemarsum in Friesland. Of his parentage (apart from his patronymic) and education nothing is known. He was not a man of learning, nor had he many books; for his knowledge of early Christian writers he was partly indebted to the Chronica or compilations of Sebastian Franck. At the age of twenty-four he entered the priesthood, becoming one of the curates under the incumbent of Pingium, a village near his birthplace. In 1516 he took the name of "Peter." He adopted the two main tenets of the Mennonites, freedom from the Sanhedral, or law, and self-indulgent living. Doubts about transubstantiation made him uneasy; some of Luther's tracts fell in his way, and he was comforted by Luther's dictum that salvation does not depend on human dogmata. Hence he began to study the New Testament. The question as to the right age for baptism came up; he found this an open matter in the early church. Then the execution, in March 1531, at Leeuwarden, of the tailor Sicke Freers, who had been rebaptized in the previous December at Emden, introduced further questions. Menno was not satisfied with the inconsistent answers which he got from Luther, Bucer and Bullinger; he resolved to rely on Scripture alone. From this time describes his preaching as evangelical, not sacramental. In 1532 he exchanged his curacy for a living at Wittemarsum, in reply to a popular call. Anabaptism of the Münster type
repelled him. His first tractate (1535, first printed 1627) is directed against the “horrible and gross blasphemy of John of Leiden”—though the genuineness of this tract has been doubted. A brother of Menno joined the insurgent followers of John Matthyszoon, and was killed at Bolsward (April 1535). Blaming the leaders by whom these poor people had been misled, Menno blamed himself for not having shown them a straight course. Accordingly on the 12th of January 1536, he left the Roman communion. There were now among the so-called Anabaptists four parties, the favourites of the Münster faction, the Batenburgers, extremists, the Melchiorites and the Obbenites. For a time Menno remained aloof from both Melchior Hofman and Obbe Philipsz. Before the year was out, yielding to the prayer of six or eight persons who had freed themselves from the Münster spell, he agreed to become their minister, and was set apart (January 1537) to the eldership at Groningen, with imposition of hands by Obbe Philipsz, who is regarded as the actual founder of the Mennonite body. In fact, Obbe left the body and is stigmatized as its Demas. Menno repudiated the formation of a sect; those who had experienced the “new birth” were to him the true Christian church, which was limited by no decree of reprobation. His Christology was in the main orthodox, though he rejected terms (such as Trinity) which he could not find in Scripture, and held a Valentinian doctrine of the celestial origin of the flesh of Christ. His church discipline was drawn from the Swiss Baptists. Silent prayer was a feature of the worship; sermons were without text. Neither baptism (by pouring on the head) nor the Lord’s Supper (with the alcohol and consecrated bread) were divine ordinances which reflected the believer’s inward state. Marriage with outsiders was prohibited; women had no part in church government. Oaths and the taking of life were absolutely forbidden; hence the magistracy and the army were for the Mennonite unlawful callings; but magistrates were to be obeyed in all things not prohibited by Scripture. The subsequent career of Menno was that of an active missionary; his changes of place, often compulsory, are difficult to trace. He was apparently much in East Friesland till 1541; in North Holland, with Amsterdam as centre, from 1541 to 1543; again till 1545 in East Friesland (where he held a disputation at Emden with John à Lasco in January 1544); till 1547 in South Holland; next, about Lübeck; at Wismar in 1553-1554 (he held two disputations with Martin Micronius at Norden in February 1554); lastly at Wüstenfelde, a village near Oldesloo, between Hamburg and Lübeck, where he died on the 13th of January 1559. He had married one Gertrude at Groningen, and left a daughter, by whom the dates of his birth and death were communicated to P. J. Twisch, for his Chronyck (1619).

Menno’s writings in Plattdeutsch, printed at different places, are numerous, with much namelessness, and what an unfriendly critic would call wool-gathering; through them shines a character attractive by the sincerity of its simple and warm spirituality, the secret of Menno’s influence. The collection of his Opera Omnia Theologica (Amsterdam, 1681), folio, in a Dutch version, comprises twenty-three tracts, with reference to nine unprinted. His main principles will be found in his Das Fundament des Christleiken Leers (1559, 5vo). A selection (Gedachtenblitter) from his writings, in a German version, in honour of the (supposed) tercentennial of his death was edited by J. Mannhardt (Danzig, 1881) with an appendix from the writings of Dirk Philipsz (1594-1679), brother of Obbe, and Menno’s benchmark. His writings are published in English at Elkhart, Indiana.

Since the publication of the Levon (1837) by A. M. Cramer, light has been thrown on the period by the researches of de Hoop Scheffer; see in the Antw. Nederl. Nieuwsb. (1840), H. M. B. van der Heide, heer R. Barclay, Inner Life of Religious Societies of the Commonwealth (1876) for a good account of Mennonite anticipations of Quaker views and practices; F. C. Fleischer, Menno Simons, eene Lavensschets (1872, Amsterdam); Menno Simons: Onze Vaderl. (1873, Groningen); Cramer; in Hauck’s Realencyklopdie (1903); a separate article in the same, Mennonien, by S. Cramer, gives a survey of the origin and ramifications of the movement in Europe and America. (A. Go.)

MENOMINEE—MENSHIKOV

MENOMINE, a city and the county-seat of Menominee county, Michigan, U.S.A., on the Green Bay, at the mouth of the Menominee river, opposite Marinette, on the line of the Michigan Central railroad, on the western extremity of the upper peninsula. Pop. (1890), 10,630; (1900), 12,818, of whom 11,456 were foreign-born; (1910 census), 15,507. It is served by the Chicago & North-Western, the Chicago, Milwaukee & St Paul, the Wisconsin & Michigan, and the Ann Arbor railways, and is connected by five bridges with Marinette, Wisconsin. Menominee has several parks, and harbour and dock facilities for the heaviest lake vessels. It is one of the largest lumber centres in the United States; it has excellent water power, and there are manufactures of wire, steel, electrical appliances, mill and mining machinery, shoes, beet sugar and paper. The use of beef pulp instead of India corn ensilage for dairy cows has promoted the dairying industry from the outset.

A trading post was established here in 1799, but settlement was not begun until 1833. Menominee became the county-seat in 1874, was chartered as a city in 1883, and in 1901 it was re-chartered; in 1903 an amendment to the charter created a municipal court. The city is named after the Menominee Indians, an Algonquian tribe formerly ranging over a considerable territory in Wisconsin and Michigan, who seem to have been first visited by whites in 1634, when Nicolet found them at the mouth of the Menominee river, and now number about 1,600, most of them being under the Green Bay school superintendent, Wisconsin. The name is the Chippewa word for wild rice, which formed part of the food of the tribe.

MENOMONIE, a city and the county-seat of Dunn county, Wisconsin, U.S.A., about 64 m. E. of St Paul, Minnesota, on the Red Cedar river. Pop. (1860), 5191; (1900), 5635, of whom 1772 were foreign-born; (1905), 5473; (1910), 5036. It is served by the Chicago, Milwaukee & St Paul, and the Chicago, Milwaukee, & Omaha railways. The city is widely known for its institute of agriculture, mainly founded in 1856 by James Huff Stout (1848-1910), a prominent local lumberman. Among them are the Mabel Tainter Memorial Library, the Dunn County School of Agriculture, the Dunn County Normal Training School, the Stout Institute for the training of teachers of domestic science &c., institutions in which public school children receive physical training. The city has grain elevators, and manufactures of bricks and tiles, foundry and machine shop products, carriages and wagons and flour. Menomonee is an important market for dairy products and livestock. Menomonee was settled about 1846 and was chartered as a city in 1882. The first free travelling library in the state was established here in 1856 by James Huff Stout.

MENSA and MAREA, semi-nomad pastoral tribes of Africans occupying part of the Abyssinian highlands included in the Italian colony of Eritrea, and the adjacent coast plains of the Red Sea. They have for neighbours the Habab and Beni-Amer tribes, as well as Abyssinians. The Marea are found chiefly in the valley of the Khor Anebu, the Mensa dwelling farther north. These tribes claim Arab origin, tracing their descent from an unchurched Coptic of the Prophet. Under Abyssinian rule they were Christians, but became Mahommedans in the 10th century. They speak a dialect of Tigrean (Abyssinian). On the death of a Marea the head of every dependent tigrē or slave family must give his heirs a cow. The tribes avenge an illegitimate birth by putting parents and child to death.

MENSHIKOV, ALEXANDER DANILOVICH, PRINCE (1663-1729), Russian statesman, was born not earlier than 1660 nor later than 1663. It is disputed whether his father was an ostler or a bargee. At the age of twenty he was gaining his livelihood as a dealer in softfurs of Moscow as a vendor of meat-pies. His handsome looks and smart sallies attracted the attention of François Lefort, Peter’s first favourite, who took him into his service and finally transferred him to the tsar. On the death of Lefort in 1699, Menshikov succeeded him as prime favourite. Ignorant, brutal, grasping and corrupt as he was, he deserved the confidence of his master. He could drill a regiment, build a frigate, administer a province, and decapitate a rebel with equal facility. During the tsar’s first foreign tour, Menshikov worked by his side in the dockyards of Amsterdam, and acquired a thorough knowledge of colloquial Dutch and German. He took an active

MENSHIKOV

part in the Azov campaigns (1695-96), and superseded Ogilvie as commander-in-chief during the retreat before Charles XII. in 1708, subsequently participating in the Battle of Holowczyn, the reduction of Mazepe, and the crowning victory of Poltava (June 26, 1709), where he won his marshal's baton. From 1709 to 1714 he served during the Courland, Holstein and Pomeranian campaigns, but then, as governor-general of Inghria, with the rank of Major-General, took a leading part in the civil administration. Menshikov understood perfectly the principles on which Peter's reforms were conducted, and was the right hand of the tsar in all his gigantic undertakings. But he abused his omnipotent position, and his depredations frequently brought him to the verge of ruin. Every time the tsar returned to Russia he received fresh accusations of peculation against his Serene Highness.1 Peter's first serious outburst of indignation (March 1711) was due to the prince's fruitless policy in Poland. On his return to Russia in 1712, Peter discovered that Menshikov had winked at wholesale corruptions in his own governorship. Peter warned him "for the last time" to change his ways. Yet, in 1713, he was implicated in the famous Solov'ev process, in the course of which it was demonstrated that he had defrauded the government of 100,000 roubles. He only owed his life on this occasion to a sudden illness. On his recovery Peter's fondness for his friend overcame his sense of justice. In the last year of Peter's reign fresh frauds and defalculations of Menshikov came to light, and he was obliged to appeal for protection to the empress Catherine. It was chiefly through the influence of Menshikov that she came to the throne. Solov'ev and his colleagues, of which Menshikov was the last, was raised to the throne. Menshikov was committed to the Petrine system, and he recognized that, if that system were to continue, Catherine was, at that particular time, the only possible candidate. Her name was a watchword for the progressive faction. The placing of her on the throne meant a final victory over ancient prejudices, a vindication of the new ideas of progress.

During her short reign (February 1725—May 1727), Menshikov was practically absolute. On the whole he ruled well, his difficult position serving as some restraint upon his natural inclinations. He contrived to prolong his power after Catherine's death by means of a forged will and a coup d'état. While his colleague Tolstoi would have raised Elizabeth Petrovna to the throne, Menshikov set up the youthful Peter II., son of the tsarevich Alexius, with himself as dictator during the prince's minority. He now aimed at establishing himself definitely by marrying his daughter Mary to Peter II. But the old nobility, represented by the Dolgorukis and the Golitsins, united to overthrow him, and he was deprived of all his dignities and offices and expelled from the capital (Sept. 9, 1727). Subsequently he was deprived of his enormous wealth, and his whole family were banished to Siberia, where he died on the 12th of November 1729.

See G. V. Eispov, Biography of A. D. Menshikov (Russ.) (St. Petersburg, 1875); N. I. Kostomarov, The History of Russia in the biographies of her great Men (Russ.), vol. ii. (St. Petersburg, 1888, etc.); R. Nisbet Bain, The First Romanov (London, 1905; ibid. The Pilgrimage of Peter the Great, ch. 2-4 (Westminster, 1897). (R. N. B.)

MENSHIKOV, ALEXANDER SERGEIEVICH, PRINCE (1787—1869), great-grandson of the preceding, was born on the 11th of September 1787, and entered the Russian service as attaché to the embassy at Vienna. He accompanied the emperor Alexander throughout his campaigns against Napoleon, and retired from army service in 1823. He then devoted himself to naval matters, became an admiral in 1834, and put the Russian navy, which had fallen into decay during the reign of Alexander, on an efficient footing. At the time of the dispute as to the Holy Places he was sent on a special mission to Constantinople, and when the Crimean war broke out he was appointed commander-in-chief by land and sea. He commanded the Russian army at the Alma and in the field operations round Sevastopol. In March 1855 he was recalled, ostensibly and perhaps really, on account of failing health. He died on the 2nd of May 1869 at St. Petersburg.

MENSURATION (Lat. mensura, a measure), the science of measurement; or, in a more limited sense, the science of numerical representation of geometrical magnitudes.

1. Scope of the Subject.—Even in the second sense, the term is a very wide one, since it comprises the measurement of angles (plane and solid), lengths, areas and volumes. The measurement of angles belongs to trigonometry, and it is convenient to regard the measurement of the lengths of straight lines (i.e. of distances between points) as belonging to geometry or trigonometry; while the measurement of curved lengths, except in certain special cases, involves the use of the integral calculus. The term "mensuration" is therefore ordinarily restricted to the measurement of areas and volumes, and of certain simple curved lengths, such as the circumference of a circle.

2. This restriction is to a certain extent arbitrary. The statement that, if the adjacent sides of a rectangle are represented numerically by $x$ and $y$, the diagonal is represented by $\sqrt{x^2 + y^2}$, is a curious example of mensuration, in which the area is represented by $xy$. The restriction is really determined by a difference in the methods of measurement. The distance between two points can, at any rate in theory, be measured directly, by successive applications of the unit of measurement. But an area or a volume cannot generally be measured by successive applications of the unit of area or volume; intermediate processes are necessary, the result of which is expressed by a formula. The chief exception is in the use of liquid measure; this is of importance from the educational point of view (§ 12).

3. The measurement is numerical, i.e. it is representation in terms of a unit. The process of determining the area or volume of a given figure therefore involves two separate processes: viz. the direct measurement of certain magnitudes (usually lengths) in terms of a unit, and the application of a formula for determining the area or volume from these data. Mensuration is not concerned with the first of these two processes, which forms part of the art of measurement, but only with the second. It might, therefore, be described as that branch of mathematics which deals with formulæ for calculating the numerical measurements of lengths, areas and volumes, in terms of numerical data which determine these measurements.

4. It is also convenient to regard as coming under mensuration the consideration of certain derived magnitudes, such as the moment of a plane figure with regard to a straight line in its plane, the calculation of which involves formulæ which are closely related to formulæ for determining areas and volumes.

5. On the other hand, the scope of the subject, as described in § 3, is limited by the nature of the methods employed to obtain formulæ which can be applied to actual cases. Up to a certain point, formulæ of practical importance can be obtained by the use of graphical methods. Graphical methods are useful and convenient methods. Beyond this point, analytical methods must be adopted, and the student passes to trigonometry and the infinitesimal calculus. These investigations lead, in turn, to further formulæ, which, though not obtainable by elementary methods, are nevertheless simple in themselves and of practical utility. If these are included in the description of "mensuration," the subject thus consists of two heterogeneous portions—elementary mensuration, comprising methods and results, and advanced mensuration, comprising certain results intended for practical application.

6. Mensuration, then, is mainly concerned with quadrature-formulæ and cubature-formulæ, and, to a not very clearly defined extent, with the methods of obtaining such formulæ; a quadrature-formula being a formula for calculating the numerical
MENSURATION

representation of an area, and a cubature-formula being a formula for calculating the numerical representation of a volume, in terms, in each case, of the numerical representations of particular data which determine the area or the volume.

7. This use of formulae for dealing with numbers, which express magnitudes in terms of units, constitutes the broad difference between mensuration and ordinary geometry, which knows nothing of units. Mensuration involves the use of geometrical theorems, but it is not concerned with problems of geometrical construction. The area of a rectangle, for instance, is found by calculation from the lengths of the sides, not by construction of a square of equal area. On the other hand, it is worth noticing that the words "quadrature" and "cubature" are originally due to geometrical rather than numerical considerations; the former implying the construction of a square whose area shall be equal to that of a given surface, and the latter the construction of a cube whose volume shall be equal to that of a given solid.

8. There are two main groups of subjects in which practical needs have tended to develop a separate science of mensuration. The first group comprises such subjects as land-surveying; here the measurements in the elementary stages take place in a plane, and the consideration of volumes necessarily constitutes a later stage; and the figures to be measured are mostly not moveable, so that triangulation plays an important part. The second group comprehends the mechanical arts, in which the bodies to be measured are solid bodies which can be handled; in these cases plane figures appear mainly as sections of solids. In developing a system of mensuration-formulae the importance of this latter group of cases must not be overlooked.

A third group, of increasing importance, comprises cases in which curves or surfaces arise out of the application of graphic methods in engineering, physics and statistics. The general formulae applicable to these cases are largely approximative.

9. Relation to other Subjects.—As a result of the importance both of the theorems obtained by elementary methods and of those which have involved the previous use of analysis, there is a tendency to dissociate the former, like the latter, from the methods by which they have been obtained, and to regard mensuration as consisting of those mathematical formulae which are concerned with the measurement of geometrical magnitudes (including lengths), or, in a slightly wider sense, as being the art of applying these formulae to specific cases. Such a body of formulae cannot, of course, be regarded as constituting a science; it has no power of development from within, and can only grow by accretion. It may be of extreme importance for practical purposes; but if it is studied apart from the methods by which the formulae are obtained, is slight. Vitality can only be retained by close association with more abstract branches of mathematics.

10. On the other hand, mensuration, in its practical aspect, is of importance for giving reality to the formulae themselves and to the principles on which they are based. This applies not only to the geometrical principles but also to the arithmetical principles, and it is therefore of importance, in the earlier stages, to keep geometry, mensuration, and arithmetical in close association with one another; mensuration forming, in fact, the link between arithmetical and geometry.

11. It is in reference to the measurement of areas and volumes that it is of special importance to illustrate geometrical truths by means of concrete cases. That the area of a parallelogram is equal to the area of a rectangle on the same base and between the same parallels, or that the volume of a cone is one-third that of a cylinder on the same base and of the same height, may be established by a proof which is admitted to be rigorous, or be accepted in good faith without proof, and yet fail to be a matter of conviction, even though there may be a clear conception of the relative lengths of the diagonal and the side of a square or of the relative contents of a rectangle and a parallelogram. Failure seems (§ 2) to be due to difficulty in realizing the numerical expression of an area or a solid in terms of a specified unit, while the same difficulty does not arise in the case of linear measure or liquid measure, where the number of units can be ascertained by direct counting. The difficulty is perhaps less for volumes than for areas, on account of the close relationship between solid and fluid measure.

9. The main object to be aimed at, therefore, in the study of elements of mensuration, is that the student should realize the possibility of the numerical expression of areas and volumes. The following are some important points.

(i) The double aspect of an area should be borne in mind; i.e. area should be treated not only as length multiplied by length, but also as volume divided by thickness. There are, indeed, certain advantages in preferring the latter to the former, and in proceeding from volumes to areas rather than from areas to volumes. While, for instance, it may be difficult to realize the equality of area of two plots of ground of different shapes, it may be easy to realize the equality of the amounts of a given material that would be required to cover them to a particular depth. This method is unconsciously adopted by the teacher who illustrates the equality of area of two geometrical figures by cutting them out of cardboard of uniform thickness and weighing them.

(ii) The very earliest stages of mensuration should be directly associated with simple arithmetical processes.

(iii) Association of solid measure with liquid measure, presenting numerical measurements of different aspects obtained by testing volumes as found from linear dimensions with the volumes of the same bodies as found by the use of measures of capacity. Here, as usual, the British systems of measures produce a difficulty which would not arise under the metric system.

(iv) Solids of the same substance should be compared by measuring and also by weighing; the comparison being then extended to areas of uniform thickness above.

(v) The idea of an average may be introduced at an early stage, methods of calculating an average being left to a later stage.

13. Classification.—The methods of mensuration fall for the most part under one or other of three main heads, viz. arithmetical mensuration, geometrical mensuration, and analytical mensuration.

14. The most elementary stage is arithmetical mensuration, which comprises the measurement of the areas of rectangles and of parallelograms. The measurement of solids may be divided into the measurement of solids being used for the mensuration of areas, and cubical blocks for the mensuration of volumes. The measure of the area of a rectangle is thus presented as the product of the measures of the sides, and arithmetical and mensuration are developed concurrently. The commutative law for multiplication is directly illustrated; and subdivisions or groupings of the units lead to such formulae as \((a + b)(b + c) = a b + a c + b c + a b + a c + b c\). Association with other branches of science is maintained by such methods as those mentioned in § 12.

15. The use of the square bricks familiarizes the scholar with the ideas of parallel lines, of equality of lengths, and of right angles. The conception of the right angle is strengthened, by contrast, by the use of bricks in the form of a rhombus.

16. The next stage is geometrical mensuration, where geometrical methods are applied to determine the areas of plane rectilinear figures and the volumes of solids with plane faces. The ordinary process involves three separate steps. The first step is the establishment of the exact equality of congruence of two geometrical figures. In the case of plane figures, the congruence is tested by an imaginary superposition of one figure on the other; but this may more simply be regarded as the superposition, on either figure, of the image of the other figure on a contiguous plane. In the case of solid figures a more difficult geometrical abstraction is involved. The second step is the conversion of one figure into another by a process of dissection, followed by rearrangement of parts; the figure as rearranged being one whose area or volume can be calculated by methods already established. This is the process adopted, for instance, for comparison of the area of a parallelogram with that of a rectangle on the same base and of the same height. The third step is the arithmetical calculation of the area or volume of the rearranged figure. These last two steps may introduce figures which have to be subtracted, and which therefore have to be treated as negative quantities in the arithmetical calculation.
MENSURATION

The difficulties to which reference has been made in § 11 are largely due to the abstract nature of the process involved in the second of the above steps. The difficulty should, wherever possible, be removed by making the process of division and reassembly complete. This is not always done. To say, for instance, that the area of a right-angled triangle is half the area of the rectangle contained by the two sides, is not to say what the area is, but what it is the half of. The proper statement is that, if \( a \) and \( b \) are the sides, the area is equal to the area of a rectangle whose sides are \( a \) and \( \frac{1}{2}b \); this being, in fact, a particular case of the proposition that the area of a trapezium is equal to the area of a rectangle whose area is its breadth and the arithmetic mean of the lengths of the two parallel sides. This mode of statement helps to establish the idea of an average. The demonstration of the formula \( \frac{1}{2}ab \), where \( a \) and \( b \) are numbers, should be regarded as a later step.

Elementary trigonometrical formulae, not involving the conception of an angle as generated by rotation, belong to this stage; the additional geometrical idea involved being that of the proportionality of the sides of similar triangles.

10. The third stage is analytical mensuration, the essential feature of which is that account is taken of the manner in which a figure is generated. To prevent discontinuity of results at this stage, recapitulation from an analytical point of view is desirable. The result of this stage, however, has so far been regarded as a plane figure bounded by one pair of parallel straight lines and another pair at right angles to them, so that the conception of "rectangularity" had reference to boundary rather than to content; analytically, the rectangle must be regarded as the figure generated by an ordinate of constant length moving parallel to itself with one extremity on a straight line perpendicular to it. This is the simplest case of generation of a plane figure by a moving ordinate; the corresponding figure for generation by rotation of a radius vector is a circle.

To regard a figure as being generated in a particular way is essentially the same as to regard it as being made up of a number of successive elements, so that the analytical treatment involves the ideas and the methods of the infinitesimal calculus. It is not, however, necessary that the notation of the calculus should be employed throughout.

A plane figure bounded by a continuous curve, or a solid figure bounded by a continuous surface, may generally be most conveniently regarded as generated by a straight line, or a plane area, moving in a fixed direction at right angles to itself, and changing as it moves the equations of the sides of the generating elements; the use of Cartesian co-ordinates leads to important general formulae, such as Simpson's formula.

The treatment of an angle as generated by rotation, the investigation of the relations between trigonometrical ratios and circular measure, the application of interpolation to trigonometrical tables, and the general use of graphical methods to represent continuous variation, all imply an analytical outlook, and must therefore be deferred to this stage.

11. There are certain special cases where the treatment is really analytical, but where, on account of the simplicity or importance of the figures involved, the analysis does not take a prominent part.

(i) The circle, and the solid figures allied to it, are of special importance. The ordinary definition of a circle is equivalent to definition as the figure generated by the rotation of a radius of constant length in a plane, and is thus essentially analytical. The ideas of the centre and of the constancy of the radius do not, however, enter into the elementary conception of the circle as a solid figure. This elementary conception is of the figure as already existing, rather than of its method of description; the test of circularity being the possibility of rotation within a surrounding figure so as to keep the two boundaries always completely in contact. In the elementary conception of the circle the idea of the sphere, which would be tested in a similar way, and is in fact so tested, at an early stage by tangential perception, and at a more advanced stage by mechanical methods; the next step being the development of the central idea, as roughly tested (where the sphere is small) by visual perception, i.e. in effect, by the circularity of the cross-section of a circumscribing cylinder; and the ideas of the centre and of non-central sections follow later.

It seems to follow that the consideration of the area of a circle should precede the consideration of its perimeter, and that the consideration of the volume of a sphere should precede the consideration of its surface-area. The proof that the area of a circle is proportional to the square of its diameter would therefore precede the proof that the perimeter is proportional to the diameter; the former being the simpler and easier, since the conception of the sum of the lengths of a curved line as the limit of the sum of a number of straight lengths presents special difficulties. The ratio \( \frac{r}{d} \) would thus first appear as the ratio of the average breadth of a circle to the greatest breadth; this interpretation as that of the circumference to the diameter being a secondary one. This order follows, in fact, the historical order of development of the subject.

(ii) Developable surfaces, such as the cylinder and the cone, form a more general class, so far as the calculation of their area is concerned. The process of unrolling is analytical, but the unrolled area can be measured by methods not applicable to other surfaces.

12. The solids of revolution of this special class which can be conveniently treated by the two theorems of Pappus (§ 33).

18. The above classification relates to methods. The classification of results, i.e. of formulae, will depend on the purpose for which the collection of formulae is required, and may involve the grouping of results obtained by very different methods. A collection of formulae relating to the circle, for instance, would comprise not only geometrical and trigonometrical formulae, but also approximate formulae, such as Huygen's rule (§ 91), which are the result of advanced analysis.

The present article is not intended to give either a complete course of study or a complete collection of formulae, and therefore such only of the ordinary formulae are given as are required for illustrating certain general principles. For fuller discussion reference should be made to GEOMETRY and TRIGONOMETRY, as well as to the articles dealing with particular figures, such as CIRCLES, CYLINDERS, and SPHERES.

19. The most important formulae are those which correspond to the use of rectangular Cartesian co-ordinates. This implies the treatment of a plane or solid figure as being wholly comprised between two parallel lines or planes, regarded by convention as being vertical; the figure being generated by an ordinate or section moving at right angles to itself through a distance which is called the breadth of the figure. The length or area obtained by dividing the area or the volume of the figure by its breadth is the mean ordinate (mean height) or mean section (mean sectional area) of the figure.

Quadrature-formule or cubature-formule may sometimes be conveniently replaced by formulae giving the mean ordinate or mean section. In the early stages it is best to use both methods, so as to develop the idea of an average (§ 12). In the present article the formulae for area or volume will be used throughout.

20. Approximation.—The numerical result obtained by applying a formula to particular data will generally not be exact. There are two kinds of causes producing want of exactness.

(i) The formula itself may not be numerically exact. This may happen in either of two ways.

(a) The formula may involve numbers or ratios which cannot be expressed exactly in the ordinary notation. This is the case, for instance, with formulae which involve \( \pi \) or trigonometrical ratios. This inexactness may, however, be ignored, since the numbers or ratios in question can generally be obtained to a greater degree of accuracy than the other numbers involved in the calculation (see (ii) below).

(b) The formula may only be approximate. The length of the arc of a circle, for instance, is known if the length of the chord and its distance from the middle point of the arc are known; but it may be more convenient in such a case to use a formula such as Huygens' rule than to obtain a more accurate result by means of trigonometrical tables.

(ii) The data may be such that an exact result is impossible.

(a) The nature of the bounding curve or surface may not be exactly known, so that certain assumptions have to be made, a formula being then used which is adapted to these assumptions. In this case the approximation is usually in the form of an overestimate, based on the idea of sphericity, which would be tested in a similar way, and is in fact so tested, at an early stage by tangential perception, and at a more advanced stage by mechanical methods; the next step being the development of the central idea, as roughly tested (where the sphere is small) by visual perception, i.e. in effect, by the circularity of the cross-section of a circumscribing cylinder; and the ideas of the centre and of non-central sections follow later.

(b) It must, however, be remembered that in all practical applications of formulae the data have first to be ascertained by direct measurement; and this measurement involves a certain margin of error.
MENSURATION

The two sources of error mentioned under (a) and (b) above arc closely connected. Suppose, for instance, that we require the area of a circular grass-plot of measured diameter. As a matter of fact, no grass-plot is truly circular; and it might be found that the breadth in various directions measured were not accurately the same, but would reveal itself. Thus the inaccuracy in taking the measured diameter as the datum is practically of the same order as the inaccuracy in taking the grass-plot to be circular. (iii) In dealing with cases where actual measurements are involved, the error (i) due to inaccuracy of the formula will often be negligible in comparison with the error (ii) due to inaccuracy of the data. For this reason, formulæ which will only give approximate results are usually classed together as rules, whether the inaccuracy lies (as in the case of Huygens’ rule) in the formula itself, or (as in the case of Simpson’s rule) in its application to the data. 21. It is necessary, in applying formulæ to specific cases, not to go the whole range of the data, but to remember that the measurements are only approximate, but also, on the other hand, to give to any ratio such as \( \pi \) a value which is at least more accurate than the measurements. Suppose, for instance, that in the example given in § 20 the diameter as measured is 1 ft. 3 in. If we take \( \pi =3.14 \) and find the area to be 26 sq. ft., the value of the square feet would require to be corrected by at least 22 per cent. Between this, and the figures of the 22. Areas of Plane Rectilinear Figures.—The following are expressions for the areas of some simple figures; the expressions in (i) refer to the figures as given diagrammatically, while those in (iii) involve dissection and rearrangement. (i) Square: side \( a \). Area = \( a^2 \). (ii) Rectangle: sides \( a \) and \( b \). Area = \( ab \). (iii) Right-angled triangle: sides \( a \) and \( b \), enclosing the right angle. Area = \( \frac{1}{2}ab \). (iv) Parallelogram: two opposite sides \( a \) and \( b \), distance between them \( h \). Area = \( ah \). (v) Triangle: one side \( a \), distant \( h \) from the opposite angle. Area = \( \frac{1}{2}ah \). (vi) Trapezium: the area is obtained by the sum of the perpendiculars drawn from the mid-points of the parallel sides to the opposite sides. The trapezium is also sometimes called a "trapezoid," but it will be convenient to reserve this term for a different figure (§ 24). The most important form of trapezium is that in which one of the two parallel sides is equal to the other and the figure is at right angles to the two parallel sides. The trapezium is then a right trapezium; the two parallel sides are called the sides, the side at right angles to them the base, and the other side the leg. By producing the two parallel sides of any trapezium (e.g. a parallelogram), and drawing a line at right angles to them, outside the figure, we see that it may be treated as the difference of two right trapeziums. (v) The trapezium is more simple to convert into a single right trapezium. Let CABB (fig. 1) be a trapezium, the sides CA and DB being parallel. Draw any straight line at right angles to CA and DB (produced if necessary), meeting them in M and N. Along CA and DB, on the same side of MN, take \( MA' = CA, NB' = DB \); and join \( AB' \). Then \( MA'NB' \) is a right trapezium, whose area is equal to that of \( CABB \); and it is related to the latter in such a way that, if any two lines parallel to AC and BD meet AB, CD, MN, \( AB' \), in \( E, G, P, E' \), and \( F, H, Q, F' \), respectively, the area of the piece \( PEQF' \) on the right trapezium is equal to the area of the piece \( GEQF' \) of the parallelogram. The right trapezium so constructed may be called the equivalent right trapezium. In the case of a parallelogram the equivalent right trapezium is a rectangle; in the case of a triangle, it is a right-angled triangle. 24. If we take a series of right trapezia, such that one side \( (\text{§ 23}) \) of the first is equal to one side of the second, the other side of the second is equal to one side of the third, and so on, and place them with their bases in a straight line and their equal sides adjoining each other we get a figure such as MABCDEF (fig. 2), which has two parallel sides MA and SF, a base MS at right angles to these, and half the area of the parallelogram. This figure is one in which no part of the figure is outside the space between MA (produced) and SF (produced). A figure of this kind will be called a trapezoid.

(i) If from the other angular points \( B, C, D, E \), perpendiculars \( BN, CP, DQ, ER \), are drawn to the base MS (fig. 2), the area is \( MN(MA + NB + NP + \frac{1}{2}QR + RS + SF) \). The lines \( MA, NB, PC, \ldots \) are called the ordinates to the parallel sides \( A, B, C, \ldots \) from the base MS, and the portions \( MN, PQ, \ldots \) of the sides \( AB, BC, CD, \ldots \) are the projections of the sides \( AB, BC, CD, \ldots \) on the base.

(ii) A special case is that in which \( A \) coincides with \( M \) and \( F \) with \( S \). The figure then stands on a base MS, the remainder of its boundary being a broken line from \( M \) to \( S \). The formula then becomes

\[ \text{area} = \{\text{MP} + \text{NB} + \text{NQ} + \text{PC} + \ldots + \text{QS} \}. \]

The value of \( \pi \) for duodecimal arithmetic is given by \[ 3+\frac{1}{2}+\frac{1}{3}+\frac{1}{4}+\frac{1}{5}+\frac{1}{6}+\frac{1}{7}+\frac{1}{8}+\frac{1}{9}+\frac{1}{10}+\frac{1}{11}+\frac{1}{12}. \]

25. To find the area of any rectilinear figure, various methods are available.

(i) The figure may be divided into triangles. The quadrilateral, for instance, consists of two triangles, and its area is the product of half the length of one diagonal by the sum of the perimeters of the two triangles drawn to this diagonal from the other two angular points. For figures of more than four sides this method is usually combined with or substituted for some simple cases as that of a regular polygon, which can be divided into triangles by radii drawn from its centre.

(ii) Suppose that two angular points \( C \) and \( E \) are given, and \( C \), \( E \) are to form a diagonal AE, and that the whole of the figure lies between lines through \( A \) and \( E \) at right angles to \( AE \). Then the figure is (usually) the sum of two trapezoids on base \( AE \), and its area can be calculated as in § 24. Fig. 3 is exhibited by the expressions

\[ \{AP + NB + NQ + PC + PE + QE + QF + SF + SA \}. \]

The area is evidently \( \frac{1}{2} \) the area of the parallelogram on \( AC \) and \( BD \), which is equal to the area of the trapezoid on bases \( AC \) and \( BD \). The area is easily calculated by the formula

\[ \frac{1}{2} \times (AC + BD) \times \text{altitude} \]

where the altitude is the distance from \( AE \) to the middle point of \( CD \), or any other perpendicular to \( AE \), the same as the perpendicular to the bases of the trapezoid.

(iii) If in the rhombus the diagonal is extended on one side of the figure, and drawn perpendiculars \( AO, BB, CD, \ldots \) and \( Ff, Gg \) to this line. Then, with proper attention to signs,

\[ \frac{1}{2} \times (a + a' + bb + bb' + \cdots + aa' + gg'). \]

(iv) The figure may be replaced by an equivalent trapezoid, on the system of which is explained in § 23. Take any base \( XX' \), and draw lines at right angles to this base through all the angular points of the figure.

\[ \frac{1}{2} \times (a + a' + bb + bb' + \cdots + aa' + gg'). \]
MENSURATION

Let the lines through B, G, C, D and P (Fig. 4) cut the boundary of the figure again in B’, G’, C’, D’, and P’ respectively, and meet the base X’X in K, L, M, N and P; the points A and E being at the extremities of the figure, and the lines through these meeting the base in a and e. Then, if we take ordinates K, L, M, N and P perpendicular to B’B, G’G, C’C, D’D, F’F, they will be the equivalent trapezoids, and any ordinate drawn from the top of this trapezoid will be equal to the portion of this ordinate (produced) which falls within the original figure.

26. Volumes of Solids with Plane Faces.—The following are expressions for the volumes of some simple solid figures.

(i) Parallelepiped: sides a, b, c, volume = abc.

(ii) Right prism. Volume = length of edge \times area of end.

(iii) Oblique prism. Volume = height \times area of end = length of edge \times area of cross-section.

(iv) Right triangular prism. Volume = \frac{1}{2} \times base \times height.

(v) General prism. Volume = \frac{1}{2} \times base \times height.

(vi) Pyramid. Volume = \frac{1}{3} \times base \times height.

(vii) Pyramid with rectangular base. Volume = \frac{1}{3} \times length \times width \times height.

The tetrahedron is a particular case.

(vi) Wedge: parallel edges a, b, c; area of cross-section S. Volume = \frac{1}{3} \times length \times area.

This formula holds for the general case in which the base is a trapezium; the wedge being thus formed by cutting a triangular prism by any two planes.

27. The figures considered in \(\S\) 26 are particular cases of the prismoid or prismatoid, i.e., a solid figure with two parallel plane rectangular ends, each of the other (i.e., the lateral) surfaces being a triangle with an angular point in one end of the figure and its opposite side in the other. Two adjoining faces in the same plane may together make up a trapezoid. More than two lateral faces may be defined as a polyhedron with two parallel faces containing all the vertices.

If R and S are the ends of a prismoid, A and B their areas, and \(h\) the perpendicular distance between them, the volume of the prismoid is

\[ \frac{1}{6}h(A+4C+B). \]

This is known as the prismoidal formula.

The formula is a deduction from a general formula, considered later (\(\S\) 28), and may be verified in various ways. The most instructive perhaps is to regard the prismoid as built up (by addition or subtraction) of simpler figures, which are particular cases of it.

(i) Let R and S be the vertex and the base of a pyramid. Then \(A = C = 1\) and \(B = \frac{1}{3}h(1+4C+B)\). The tetrahedron is a particular case.

(ii) Let R be one edge of a wedge with parallel ends, and S the face containing the other two edges. When \(A = 0\), \(C = 1\), and \(B = \frac{1}{3}h(1+4C+B)\).

(iii) Let R and S be two opposite edges of a tetrahedron. Then the tetrahedron may be regarded as the difference of a wedge with parallel ends, one of the edges being R, and a pyramid whose base is a parallelogram, one side of the parallelogram being S (see Fig. 6, \(\S\) 58). Hence, by (i) and (ii), the formula holds for this figure.

(iv) For the prismoid in general let ABCD... be one end, and A', B', C', D'... the other. Take any point P in the latter, and form triangles by joining P to each of the sides AB, BC, CD... and AB', BC', CD'... of the ends, and also to each of the edges. Then the prismoid is divided into a pyramid with vertex P and base ABCD... and a series of tetrahedra, each as in (i) and (ii), and the formula holds for each of these figures; and therefore it holds for the prismoid as a whole.

Another method of verifying the formula is to take a point Q in the mid-secs-plane and divide up the prismoid into two pyramids with vertex Q and bases ABCD... and AB'CD'... respectively, and a series of tetrahedra having Q and vertex as center.

28. The Circle and Allied Figures.—The mensuration of the circle is founded on the properties of different circles being proportional to the squares on their diameters.

The lengths of arcs of the same circle being proportional to the angles subtended by them at the center, we get the idea of circular measure.

Let \(O\) be the common centre of two circles, of radii \(a\) and \(b\), and let \(aa'\) and \(bb'\) be concentric circles of radius \(a\) by a concentric circle of radius \(a-e\), when \(e\) becomes indefinitely small, this is an elementary case of differentiation.

The expression 2\(\pi\) for the length of the radius is deduced by considering the limit of the area cut off from a circle of radius \(a\) by a concentric circle of radius \(a-e\) when \(e\) becomes indefinitely small; this is an elementary case of differentiation.
35. The Ellipse and the Ellipsoid.—For elementary mensuration the ellipse is to be regarded as obtained by projection of the circle, and the ellipsoid by projection of the sphere. Hence the area of an ellipse whose axes are $2a$ and $2b$ is $\pi ab$; and the volume of an ellipsoid whose axes are $2a$, $2b$ and $2c$ is $\frac{4}{3}\pi abc$. The area of a strip of an ellipse between two lines parallel to an axis, or the volume of the portion (frustum) of an ellipsoid between two planes parallel to a principal section, may be found in the same way.

36. Examples of Applications. The formula of § 24 for the area of a trapezoid are of special importance in land-surveying. The measurements of a polygonal field or other area are usually taken as in § 25 (ii); a diagonal $AE$ is taken as the base-line, and for the other side of the parallelogram take another diagonal $BC$, etc.

37. The mensuration of earthwork involves consideration of quadrilaterals whose dimensions are given by special data, and of prisms whose sections are such quadrilaterals. In the ordinary case the three of the four lateral surfaces of the prism are at right angles to the two ends. In special cases two or more of these three lateral surfaces are equally inclined to the third.

(a) If $y = a$, and let $k$ be the distance, measured at right angles to $BC$, from the middle point of $BC$ to $AD$. Also, let angle $ABC = \alpha - \theta$, angle $BCD = \pi - \phi$, angle between $BC$ and $AD = \psi$. Then (as the difference of two triangles)

$$\text{area } ABCD = \frac{1}{2}(\cot \psi - \cot \phi) - \frac{1}{2}(\cot \psi - \cot \theta).$$

(b) If $\phi = \theta$, this becomes

$$\text{area } = \frac{1}{2} \tan \theta \left(\frac{1}{\tan \phi} - \frac{1}{\tan \theta}\right) = a^2 \tan \theta.$$

(c) If $\phi = 0$, so that $AD$ is parallel to $BC$, it becomes

$$\text{area } = ab + \frac{1}{2}(\cot \phi + \cot \psi).$$

(iv) To find the volume of a prismatical cutting with vertical ends, and with sides equally inclined to the vertical, so that $\phi = \theta$, let the values of $a, b, c$ be $h_1, a_1, h_2, a_2$, and write

$$m = \cot \phi , \quad m = \cot \psi , \quad m = \cot A , \quad m = \cot a , \quad m = \cot c , \quad m = \cot b ,$$

Then volume of prism $= \pi x + m x + \frac{1}{2}(m x + m x) - \frac{3}{4}a^2 \tan \theta$.

MENSURATION OF GRAPHS

38. (A) Preliminary.—In § 23 the area of a right trapezium has been expressed in terms of the base and the two sides; and in § 34 the area of a somewhat similar figure, the top having been replaced by an arc of a parabola, has been expressed in terms of its base and of three lengths which may be regarded as the sides of two separate figures of which it is composed. We have now to consider the extension of formulation of this kind to other figures, and their application to the calculation of moments and volumes.

39. The plane figures with which we are concerned come mainly under the description of graphs of continuous variation. Let $E$ and $F$ be two magnitudes so related that whenever $F$ has any value (within certain limits) $E$ has a definite corresponding value. Let $u$ and $x$ be the numerical expressions of the magnitudes of $E$ and $F$. On any line $OX$ take a length $OQ$ equal to $x$, and from $N$ draw $NP$ at right angles to $OQ$ and equal to $uy$; $G$ and $H$ being convenient units of length. Then we may, ignoring the units $G$ and $H$, speak of $ON$ and $NP$ as being equal to $x$ and $u$, respectively. Let $KA$ and $LB$ be the positions of $P$ corresponding to the extreme values of $x$. Then the different positions of $NP$ will (if $x$ may have any value from $OK$ to $OL$) trace out a figure on base $KL$, and extending from $KA$ to $LB$; this is called the graph of $E$ in respect of $F$. The term is also sometimes applied to the line $AB$ along which the point $P$ moves as $N$ moves from $K$ to $L$.

To illustrate the importance of the mensuration of graphs, suppose that we require the average value of $u$ with regard to $x$. It may be shown that this is the same thing as the mean distance
of elements of the graph from an axis through $O$ at right angles to $OX$. Its calculation therefore involves the calculation of the area and the first moment of the graph.

40. The processes which have to be performed in the mensuration of figures of this kind are in effect processes of integration; the distinc

tion is that the position of the point in question lies and the natures of the data. If, for instance, the graph were a trapezium, the calculation of the area would be equivalent to finding the integral, from $x = a$ to $x = b$, of an expression of the form $px + q$. This would in general, but for the data, be given by the area $ab / 2 + pb / 2 - qa / 2$, and the expression of the integral in terms of this data would require certain

terminal points. The question is one of the final result of such an elimination in terms of the data, without the necessity of going through the intermediate processes.

41. Trapezettes and Briquettes.—A figure of the kind described in the last section is a trapezette. A trapezette can be regarded as a plane figure bounded by two straight lines, a base at right angles to them, and a top which may be of any shape but is such that every ordinate from the base cuts it in one point and one point only; or, alternatively, it may be defined as the figure generated by an ordinate which moves in a plane so that its foot is always on a straight base to which the ordinate is at right angles, the length of the ordinate varying in any manner at it. The distance between the two straight sides, i.e. between the initial and the final position of the ordinate, is the breadth of the trapezette. Any line drawn from the base, at right angles to it, and terminated by the top of the trapezette, is a "bounding ordinate." The area of a plane figure is a definite integral.

Either or both of the bounding ordinates may be zero; the top, in that case, meets the base at that extremity. Any plane figure whose boundary is a set of straight line segments is called a trapezette. A trapezette can be regarded as a plane figure bounded by two straight lines, a base at right angles to them, and a top which may be of any shape but is such that every ordinate from the base cuts it in one point and one point only. It may be regarded as generated either by a trapezette moving in a direction at right angles to itself and changing its top but keeping its breadth unaltered, or by an ordinate moving so that its foot has every possible position within a rectangular base.

42. The corresponding solid figure, in its most general form, is such as would be constructed to represent the relation of a magnitude $x$ to $y$ and $z$ and $G$, and $G$ is a function of $x$, $y$, and $z$; it would stand on a plane base, and be comprised within a cylindrical boundary whose cross-section might be of any shape. We are not concerned with figures of this general kind, but only with cases in which the base is a rectangle. The figure is such as would be described by removing a piece of a rectangular prism, and is called a briquette. A briquette may therefore be defined as a solid figure bounded by a pair of parallel planes and the surfaces of the prism cut by these planes. This is a case of the trapezette, is a "bounding ordinate." The area of the trapezette whose bounding ordinates are $u$ and $v$ may be denoted by $\int_{x = u}^{x = v} dy$. In the same way the volume of a briquette between the planes $x = u$, $y = v$ etc. may be denoted by $\int_{x = u}^{x = v} dy$. The statement that the ordinate $x$ of a briquette is a function of $y = f(x)$, that $u = f(x)$, and $v = f(x)$ is the equation to the top of the briquette. In practice the solid figure described by a briquette is a curve in three dimensions, or curves, while in mensuration we deal with areas bounded by these lines or curves. The circle, for instance, is regarded geometrically as a line described in a particular way, while from the point of view of mensuration it is a figure of the second order of the form of a figure of the first order.

43. The ordinate of the trapezette will be denoted by $u$, and the abscissa of this ordinate, i.e. the distance of its foot from a certain fixed point or origin $O$ on the base (or the base of the solid figure denoted by $O$) will be denoted by $x$, and the ordinate $y$ of the same point. The sides of the trapezette are the "bounding ordinates"; their abscissae being $x_0$ and $x_0 + H$, where $H$ is the breadth of the trapezette.

The "mid-ordinate" is the ordinate from the middle point of the base, i.e. the ordinate whose abscissa is $x = x_0 + H / 2$.

The "mean ordinate" or "average ordinate" is an ordinate of length $l$ such that $H$ is equal to the area of the trapezette divided by $l$ and appears as a calculated length rather than as a definite line in the figure; except that, if there is only one ordinate of this length, a line drawn through its extremities is so placed that the area of the trapezette lying above it is equal to a corresponding area below it and outside the trapezette. Formulae giving the area of a trapezette should in general also be expressed so as to state the value of the mean ordinate ($\frac{1}{2} (y_1 + y_2)$).

44. The ordinate which divides the area of the trapezette into two equal portions. It arises mainly in statistics, when the ordinate of the trapezette represents the relative frequency of the occurrence of magnitude represented by the abscissa $x$; the magnitude of the abscissa corresponding to the median ordinate is then the "median value of $x$."

The "central ordinate" is the ordinate through the centroid of the trapezette ($\frac{1}{2}$). The distance of this ordinate from the axis of $u$ (i.e. from a line drawn through $O$ parallel to the ordinates) is equal to the mean distance ($\frac{1}{2}$) of the trapezette from this axis; moments with regard to the central ordinate are therefore sometimes described as "moments of the second order." The ordinate is sometimes referred to as the "mean ordinate." The ordinate is sometimes referred to as the "mean ordinate." The ordinate is sometimes referred to as the "mean ordinate.

The data of a trapezette are usually its breadth and either the bounding ordinates or the mid-ordinates of a series of minor trapezettes into which it is divided by ordinates drawn through the vertices of the triangle. If there are $m$ of these strips, and if the breadth of each is $b$, so that $H = mb$, it is convenient to write $x$ in the form $x + b$, and to denote it by $x_0$, the corresponding value of $u$ being $u_0$. The data are then the bounding ordinates $u_0, u_1, u_2, ..., u_m$ of the strips, or their mid-ordinates $n_0, n_1, n_2, ..., n_m$.

45. In the case of the briquette the position of the foot of the ordinate $u$ is expressed by co-ordinates $x, y$, referred to a pair of axes parallel to a pair of sides of the base of the briquette. If the lengths of these sides are $H$ and $K$, the coordinates of the angles of the base, i.e. the co-ordinates of the edges of the briquette—$u_0, y_0, (x_0 + H, y_0), (x_0, y_0 + K)$, and $(x_0 + H, y_0 + K)$—are the briquette may usually be regarded as divided into a series of small trapezettes, viz. $u_0, y_0, (x_0 + H, y_0), (x_0, y_0 + K)$, and $(x_0 + H, y_0 + K)$, or of the mid-ordinates of one set of parallel faces, viz. $u_0, u_1, u_2, ..., u_m$, of the other, and of the mid-ordinates of the minor briquettes, i.e. the ordinates from the centres of their bases. Each plane parallel to either pair of sides of the briquette is a "principal plane." The ordinate through the centroid of the figure is the "central ordinate."
The volume of a briquette can be found in this way if the area of the section by any principal plane can be expressed in terms of the distance of this plane from a fixed plane of the same set. The result of treating this area as if it were the ordinate of a trapezette leads to special formulæ, when the data are of the kind mentioned in § 44.

49. (B) Mensuration of Graphs of Algebraical Functions.—The first-class cases to be considered comprise those cases in which there is an algebraical function of x, i.e., a curve of algebraical function) of x, or of x and y, of a degree which is known.

50. The simplest case is that in which x is constant or is a linear function of y, i.e., of the form px + q. The trapezette is then a right trapezium, and its area, if \( m = A + B + C \) or \( k u_1 \).

51. The next case is that in which u is a quadratic function of x, i.e., is of the form \( px^2 + qx + r \). The top is then a parabola whose axis is right angular to the base; and the odd powers of x can therefore be expressed in terms of the two bounding ordinates and the mid-ordinate. If we take these to be \( u_0 \) and \( u_1 \), so that \( m = 2 \), we have

\[
\text{area} = \frac{1}{2} (u_0 + u_2 + u_1).
\]

This is Simpson's formula.

If instead of \( u_0 \), \( u_1 \), and \( u_2 \), we have four ordinates \( u_0 \), \( u_1 \), \( u_2 \), and \( u_3 \), so that \( m = 3 \), it can be shown that

\[
\text{area} = \frac{1}{6} (u_0 + u_2 + u_4 + u_1).
\]

This is Simpson's second formula. It may be deduced from the formula given above. Denoting the areas of the three strips by A, B, and C, we have the ordinates of the mid-ordinate to the trapezette.

52. Simpson's second formula is applicable to the algebraical function \( px^2 + qx + r \). Generally, if the area of a trapezette for which \( u \) is an algebraical function of \( x \) of degree \( 2n \) is given correctly by an expression which is a linear function of values of \( u \) representing ordinates placed symmetrically about the mid-ordinate of the trapezette (with or without this mid-ordinate), the same expression will give the area of a trapezette for which \( u \) is an algebraical function of \( x \) of degree \( 2n + 1 \). This will be seen by taking the mid-ordinate as the ordinate for which \( x = 0 \), and noticing that the odd powers of \( x \) introduce positive and negative terms which balance one another when the whole area is taken into account.

53. When \( x \) is of degree \( 4 \) or \( 5 \) in \( x \), we require at least five ordinates. If \( m = 4 \), and the data are \( u_0 \), \( u_1 \), \( u_2 \), \( u_3 \), \( u_4 \), we have

\[
\text{area} = \frac{1}{120} \left( 5u_0^3 + 2u_1^3 + 3u_2^3 + 2u_3^3 + u_4^3 \right).
\]

For functions of higher degrees in \( x \) the formulæ become more complicated.

54. The general method of constructing formulæ of this kind involves the use of the integral calculus and of the calculus of finite differences. For each of the three areas being \( mh \), it may be shown that its area is

\[
\text{area} \left\{ \frac{1}{24} m^2 h^2 u_1^2 + \frac{1}{120} m^2 h^2 u_0^2 + \frac{1}{32} m h^2 u_1^2 + \frac{1}{92} mh^2 u_1 u_2 \right\},
\]

where \( u_{m+1} \), \( u_{m+2} \), \( u_{m+3} \), \ldots denote the values for \( x = x_{m+1} \) of the successive differential coefficients of \( u \) with regard to \( x \); the series continuing until the differential coefficients vanish. There are two classes of cases, according as \( m \) is even or odd; it will be convenient to consider them first for those cases in which the data are the bounding ordinates of the strips.

(i) If \( m \) is even, \( u_{m+1} \) will be one of the given ordinates, and we can express \( h^2 u_{m+1} \), \( h^2 u_{m+2} \), \ldots in terms of \( u_{m+1} \) and its even central differences (see Differences, Calculus of). Writing \( m = 2p \), and grouping the coefficients of the successive differences, we shall find

\[
\text{area} = 2ph \left( u_{m+1} + \frac{1}{6} h^2 u_{m+2} + \frac{2}{36} (h^2 u_{m+3} + 3h^2 u_{m+4} + \frac{15120}{15120} \right).
\]

If \( x \) is of degree \( 2f \) or \( 2f + 1 \), we require to go up to \( h^2 u_{m+1} \), so that \( m \) must be not less than \( 2f \). Simpson's (first) formula, for instance, holds for \( f = 1 \), and is obtained by taking \( p = 1 \) and ignoring the difference \( u_{m+1} \).

(ii) If \( m \) is odd, the given ordinates are \( u_0 \), \( u_1 \), \( u_2 \), \ldots, \( u_m \). We have then

\[
\text{area} = \frac{1}{120} \left( m^2 h^2 u_{m+1} + \frac{1}{24} h^2 u_0^2 + \frac{1}{6} h^2 u_{m+1}^2 + \frac{1}{32} m h^2 u_1^2 + \frac{1}{92} mh^2 u_1 u_2 \right),
\]

where \( u_{m+1} \), \( u_{m+2} \), \ldots denote \( u_m \), \( u_{m+1} \), \( u_{m+2} \), \ldots, \( u_{m+1} \). We then have

\[
\text{area} = \frac{1}{120} \left( m^2 h^2 u_{m+1} + \frac{1}{24} h^2 u_0^2 + \frac{1}{6} h^2 u_{m+1}^2 + \frac{1}{32} m h^2 u_1^2 + \frac{1}{92} mh^2 u_1 u_2 \right),
\]

where \( u_{m+1} \), \( u_{m+2} \), \ldots denote \( u_m \), \( u_{m+1} \), \( u_{m+2} \), \ldots, \( u_{m+1} \).
MENSURATION

BC, BD, AD, in P, Q, R S (Fig. 9). Then the section of the pyramid by this plane is the parallelogram PQRS. By drawing AC and AD, it will be seen that the plane through CD in c and d and producing PQ and RS to meet ac and AD in q and r, we see that the area of PQRS is $(c/b - x)/y$ x area of $cCd$; this also is a quadratic function of $x$. The proposition can then be established by the method of § 57 (iv) of the Algebra.

The formula is known as the prismoidal formula.

59. Moments.—Since all points on any ordinate are at an equal distance from the axis, it is evident that the integral of $x$ is $\int xdx$. The general principle is that the numerical data from which a particular result is to be deduced are in general not exact, but are given only to a certain degree of accuracy. This limits the accuracy of the solution. However, if the numerical data are given with such a degree of accuracy that the deviation from the actual result is less than the error of measurement, the result is regarded as correct.

60. The method of extension can be found by the second, third, and fourth moments of a triangle with regard to the axis of $u$. If $u$ is an algebraical function of $x$, then the position of the center of gravity of the triangle is

$$
\frac{\int x^2u(x)dx}{\int u(x)dx}
$$

and the position of the center of gravity of particles of mass $m_1, m_2, \ldots$ placed at the extremities and the middle of the line drawn from one end of the solid to the other. The center of gravity of a hemisphere of radius $R$, for instance, is the same as the center of gravity of particles of mass $m_1$, $m_2$, and $m_3$, placed at the extremities and the middle of its axis; i.e., the centroid is at distance $\frac{3R}{4}$ from the plane face.

61. Cubature of a Briquette.—To extend these methods to a briquette, where the ordinate $u$ is an algebraical function of $x$ and $y$, we consider a section $x = a$ of the briquette whose ordinate is $u = f(x, y)$. The calculation is simplified by noticing that we are only concerned with the mutual ratios of $k_1$, $k_2$, and $k_3$ of $u$ to their actual values.

62. The procedure is simplified by writing down the general formula first and substituting the values of $u$. The formula in the above case is

$$
\int \left[ (k_x u_{x_0} + 3 k_{x_1} u_{x_1} + 3 k_{x_2} u_{x_2} + \cdots + k_{x_n} u_{x_n}) + k_{y_0} u_{y_0} + \cdots \right] dx
$$

where $k_x$ denotes the ordinate for which $x = x_0, x_1, \ldots, x_n$ and $k_y$ the ordinate for which $y = y_0, y_1, \ldots, y_m$.

The above is a particular case of a general principle that the obtaining of an expression such as $h(x+4a+4u) \pm u$ or $\int u^2 \pm \int u$ is performed by the use of the prismoidal formula, and that the calculation is the sum of a number of operations such as that of $\int u_0$ or $\int u_2$. The volume of the briquette is also a function of $x$ and $y$ and is found by the method of double integration, consisting of two successive operations, one being with regard to $x$, and the other with regard to $y$; and these operations may (in the cases with which we are dealing and for any solid body) be performed by the ordinate $u \pm \phi$, the result of integrating with regard to $x$ through a distance $2h$ is (in the example considered in § 61) the same as the result of the operation $h(1 + 4E + E^2)$, where $E$ denotes the operation of changing $x$ into $x+3h$ (see Calculus, Calculus).
tangential area may be expressed in terms of chordal areas. If we write $C_i$ for the chordal area obtained by taking ordinates at intervals $x_i$, then $T_i = 2C_i$. Cz, as seen from above, is everywhere convex or everywhere concave, the true area lies between $C_i$ and $T_i$.

68. **Other Rules for Trapezettes.**—The extension of this method consists in replacing the trapezette into minor trapezettes, each consisting of two or more strips, and replacing each of these minor trapezettes by a new figure, whose ordinate $v$ is an algebraical function of $x$; this function being cibson so that the new figures shall coincide with the original figure so far as the given ordinates are concerned. This means that, if the minor trapezette consists of $k$ strips, $v$ will be of degree $k$ or $k - 1$ in $x$, according as the data are the bounding ordinates or the mid-ordinates. If $A$ denotes the true area of the original trapezette, and $B$ the aggregate area of the substituted figures, we have $A > B$, where $\Delta A$ denotes approximate equality. The value of $B$ is found by the methods of §§ 49-55.

The following are some examples.

(i) Suppose that the bounding ordinates are given, and that $m$ is a multiple of 2. Then we can take the strips in pairs, and treat each pair as a parabolic trapezette. Applying Simpson's formula to each of these, we have

$$A = \frac{1}{3}h(u_0 + 4u_1 + u_2 + 4u_3 + \ldots + 4u_{m-4} + u_{m-3} + u_{m-2}).$$

This is Simpson's rule.

(ii) Similarly, if $m$ is a multiple of 3, the repeated application of Simpson's formula is seen to give

$$A = \frac{1}{3}h(u_0 + 3u_1 + 3u_2 + 4u_3 + \ldots + 3u_{m-4} + 3u_{m-3} + u_{m-2}).$$

(iii) If mid-ordinates are given, and $m$ is a multiple of 3, the repeated application of the formula of § 55 will give

$$A = \frac{1}{3}h(u_0 + 2u_1 + 3u_2 + 3u_3 + \ldots + 2u_{m-2} + u_{m-1}).$$

69. The formulae become complicated when the number of strips in each of the minor trapezettes is large. The method is then modified by replacing the expression which gives the areas of the sub-stituted figures approximately. This introduces a further inaccuracy; but this latter may be negligible in comparison with the main inaccuracies already involved (cf. § 20 (ii)).

Suppose, for instance, that $m = 6$, and that we consider the trapezette as a whole; the data being the bounding ordinates. Since there are seven of these, $v$ will be of degree 6 in $x$, and we shall have (§ 54 (i))

$$B = 6h(u_0 + u_1 + u_2 + u_3 + u_4 + u_5 + u_6).$$

If we replace $h(u_v)$ in this expression by $h(u_v)$, the method of § 68 gives

$$A = \frac{1}{3}h(u_0 + 2u_1 + 3u_2 + 3u_3 + \ldots + 2u_{m-2} + u_{m-1}).$$

We can therefore express the area $A$ by an expression which gives the areas of the sub-stituted figures approximately. This introduces a further inaccuracy; but this latter may be negligible in comparison with the main inaccuracies already involved (cf. § 20 (ii)).

70. Some of the formulae obtained by the above methods can be expressed more simply in terms of chordal or tangential areas taken in various directions. Consider, for example, the expression

$$A = \frac{1}{3}h(u_0 + u_1 + u_2 + u_3 + \ldots + u_{m-1} + u_m),$$

which may be denoted by $C_p$. With this notation, the area as given by Simpson's rule may be written in the form $4C_1 + 4C_2 + 4C_3 + \ldots + 4C_{m-4} + C_{m-3} + C_{m-2}$. These are some examples of formulae of this kind, in terms of chordal areas.

(i) a multiple of 2 (sided trapezette).

$$A = \frac{1}{3}h(u_0 + u_1),$$

which may be denoted by $C_p$. With this notation, the area as given by Simpson's rule may be written in the form $4C_1 + 4C_2 + 4C_3 + \ldots + 4C_{m-4} + C_{m-3} + C_{m-2}$.

(ii) a multiple of 3 (Simpson's second rule).

$$A = \frac{1}{3}h(u_0 + u_1),$$

which may be denoted by $C_p$. With this notation, the area as given by Simpson's rule may be written in the form $4C_1 + 4C_2 + 4C_3 + \ldots + 4C_{m-4} + C_{m-3} + C_{m-2}$.

(iii) a multiple of 4.

$$A = \frac{1}{3}h(u_0 + 4u_1 + u_2 + 4u_3 + \ldots + 4u_{m-4} + u_{m-3} + u_{m-2}).$$

This is Simpson's rule.

(iv) a multiple of 6.

$$A = \frac{1}{3}h(u_0 + 2u_1 + 3u_2 + 3u_3 + \ldots + 2u_{m-2} + u_{m-1}).$$

51. The general method of constructing the formulae of § 70 for chordal areas is that, if $p, q, r, \ldots$ are the factors (including 1) of $m$, we take

$$A = \frac{1}{3}h(u_0 + \frac{q}{p}u_1 + \frac{r}{p}u_2 + \ldots + \frac{r}{p}u_{m-2} + \frac{q}{p}u_{m-1} + u_m).$$

Where $P, Q, R, \ldots$ satisfy the $k$ equations

$$P + Q + R + \ldots = 1,$$

$$P^2 + Q^2 + R^2 + \ldots = 0,$$

and so on.

The last $k - 1$ of these equations give

$$\begin{align*}
1/P & = 1/R, \\
1/P & = 1/R, \\
\ldots & = 1/R,
\end{align*}$$

Combining this with the first equation, we obtain the values of $P, Q, R, \ldots$

The same method applies for tangential areas, by taking

$$A = 4P_T + 4Q_T + 4R_T + \ldots.$$
MENSURATION

76. The calculation of the expressions in brackets may be simplified by taking the pairs in terms from the outside; i.e., by finding the successive differences of $u + m_4$, $u_1 + m_3$, . . . or of $u_1 + m_4$, $u_2 + m_3$, . . .

77. In order to find the corrections in respect of the terms shown in square brackets in the formulae of § 75, certain ordinates other than those used for $C_0$ or $T_1$ are sometimes found specially.\[\text{Para-

78. In order to find the corrections in respect of the terms shown in square brackets in the formulae of § 75, certain ordinates other than those used for $C_0$ or $T_1$ are sometimes found specially.\[\text{Para-

80. Moments of a Trapezette.—The above methods can be applied, as in §§ 59 and 60, to finding the moments of a trapezette, when the
MENSURATION 145

where T is the area of a trapezoid whose ordinates at successive

distances h are 0, 0', 0' 0'' 0''' 0''', . . . 0'n 0'n'. The expressions

ded to the first differential coefficient.

85. Volume and Moments of a Briquette.—The application of the

methods of §§ 75-79 to the calculation of the volume of a briquette leads to

complicated formulae. If the conditions are such that the methods of

§ 61 cannot be used, or are unsuitable for giving too much weight to

particular ordinates, it is best to proceed in the manner indicated at

the end of § 48; i.e., to find the areas of one set of parallel sections, and

treat these as the areas of a trapezoid whose area will be

the volume of the briquette.

86. The formulae of § 82 can be extended to the case of a briquette

whose top has close contact with the base all along its boundary; the

data being the volume of the minor briquettes formed by the

planes x = x0, x = x1, . . . and y = y0, y = y1, . . .

Thus we find (e.g.,

\[ S_{x0} = \int_{x0}^{x1} \int_{y0}^{y1} f(x, y) \, dx \, dy \]

where \( S_{x0} \) is the total volume of the briquette.

If the briquette are, as in § 84, the volumes of the minor briquettes, but the condition as to close contact is not satisfied, we have

\[ S_{x0} = \int_{y0}^{y1} \int_{x0}^{x1} f(x, y) \, dx \, dy \]

where \( S_{x0} \) is the total volume of the briquette.

87. If the data of the briquette are, as in § 84, the volumes of the briquettes, but the condition as to close contact is not satisfied, we have

\[ S_{x0} = \int_{y0}^{y1} \int_{x0}^{x1} f(x, y) \, dx \, dy \]

where \( S_{x0} \) is the total volume of the briquette.

The second and third expressions on the right-hand side represent areas of trapsesettes, which can be calculated from the data; the fourth expression represents the volume of a briquette, to be calculated in the same way as R above.

88. Cases of Failure.—When the sequence of differences is not such as
to enable any of the foregoing methods to be applied, it is sometimes

to possible to amplify the data by measurement of intermediate

ordinates, and then apply a suitable method to the amplified series.

There is, however, a certain class of cases in which no subdivision of

intervals is possible; i.e., the ordinates in which top of the figure is, at one extremity (or one part of its boundary), at right angles to the base. The Euler-Maclaurin formula (§ 75) assumes that the bounding values of \( y, x \), etc., are not infinite; in this case it is considered.

It is also clearly impossible to express \( y \) as an algebraic function of

x and \( y \) of some value of \( dx/dy \) or \( dy/dx \) is to be infinite.

To completely satisfy these cases, one method is to construct a table for interpo-

lation of \( y \) and \( x \) from this table to calculate values of \( y \) corresponding to

value of \( x \), proceeding by equal intervals; a quadrature-formula can then be applied.

Suppose, for instance, that we require the area of the trapesa of Fig. 11; then

this condition is not satisfied in the base at A, thereby leading to right angles at the base AL at A. If QD is the bounding ordinate of one of the component strips, we can calculate the area of QDUL in the ordinary way. The data for the area ADQ is a series of values of \( y \) corresponding to different values of \( x \); if we denote by \( y \) the distance of a point

on the arc AD from QD, we can from the series of values of \( u \) construct a series of values of \( y \) corresponding to equidifferent values of \( u \), and thus find the area of ADQ, treating QD as the base. The process, however, is the tholecule.

89. Examples of Applications.—The following are some examples of

cases in which the above methods may be applied to the calculation

of areas and integrals.

90. Construction of Actuarial Mathematical Tables.—Even where \( u \) is an explicit function of \( x \), so that \( u = x \) may be expressed in terms of \( x \), it is often more convenient, for construction of a table of values of \( u \), to use finite-difference formulae. The formula of § 63 may be (see Differences, Calculus of) be written

\[ f_{u} = k \mu_{+} x + (1 - f_{u} \mu_{0} + f_{u} \mu_{00} - ...) \]

However, in the more general case, the above formula involves an arbitrary constant; but this disappears when we start the changes from a known value of \( f_{u} \).

The process may be repeated. Thus we have

\[ f_{u} = k (\mu_{+} x + (1 - f_{u} \mu_{0} + f_{u} \mu_{00} - ...) \]

Here there are two arbitrary constants, which may be adjusted in various ways.

The formulae can be applied for extending the accuracy of tables, in cases where, if \( r \) represents the quantity tabulated, \( h(\mu_{0}dx \) or \( h(\mu_{00}dx \) can be conveniently expressed in terms of \( y \) or \( x \). The more important cases are stated in the text, and the method is illustrated by the example given in the notes (§ 56). The process practically consists in using the table as it stands for improving the first or second differences of \( y \) and then building up the table afresh.

91. MENSURATION.—The use of quadrature-formulae is important in

actuarial work, where the fundamental tables are based on experi-

ence, and the formulae applying these tables involve the use of the tabulated values and their differences.

92. The following are instances of the application of approximative

formulæ to the calculation of the volumes of solids.

6) Timber Measure.—To find the quantity of timber in a trunk with

its points of ends, the areas of the six square meters must be

measured as accurately as possible, and a formula applied. As the

measurements can only be rough, the trapezoidal rule is the most

appropriate in ordinary cases.

(7) To measure the volume of a cask, it may be assumed

that the interior is approximately a portion of a spherical

figure. The formula applied can then be either Simpson's rule

or a rule based on Gauss's work. The formula is given in

(§ 56).

93. Certain approximate formulæ for the length of an arc of a

circle are obtained by methods similar to those of §§ 71 and 79.

Let \( a \) be the radius of a circle, and \( \mu \) (circular measure) the

unknown angle subtended by an arc. Then, if we divide \( \mu \) into

\( m \) equal parts, and \( L_{1} \) denotes the sum of the corresponding

sections, so that \( L_{1} = m \mu \sin (\mu/2m) \), the true length of the arc

is \( L = m \mu (\sin \mu + \sin \mu + \ldots + \sin \mu) \), where \( \phi = \theta \mu \).

Similarly, if \( L_{2} \) represents the sum of the chords when \( m \) (assumed even) is replaced by \( \infty \), we have an expression involving \( L_{2} \) and \( \phi \).

The method of

§ 71 then shows that, by taking \( \lambda(\mu_{0}L_{1} - L_{0}) \) as the value of the

arc, we get rid of terms in \( \phi \). If we use \( c_{1} \) to represent the chord of

any arc, \( e_{2} \), the chord of half the arc, and \( c_{4} \), the chord of one

quarter of the arc, then corresponding to (i) and (iii) of § 70 or

§ 79 we have \( b \cos (\mu + \phi) + \phi \cos (\mu + \phi) \) as approximations to the

length of the arc. The method of using these approximations is

similar to that of the prismoidal formula, see

Alfred Lodge, Mensation for Senior Students (1895). Other works

on elementary mensuration are given, for example, in R. P. Sec. 3, Elements of Plane and Solid Mensuration (1902); William H. Jackson, Elementary Solid Geometry (1907); P. A. Lambert, Computation and Mensuration (1907). A. E. Pier- point's Mensation Formulae (1903) is a handy collection. Rules

for calculation of areas are also given in such works as F. C. Clarke, Manual of Practical Mathematics (1903); F. C. Clarke, Practical

Mathematics (1907); C. T. Mills, Technical Arithmetic and Geometry

FIG. 11
MENAWI—MENZEL, A. F. E. VON

(1903). For example, measurements of areas by geometrical construction, see G. C. Turner, Graphics applied to Arithmetic, Mensuration and Statics (1907). Discussions of the approximate calculation of definite integrals will be found in works on the infinitesimal calculus; see e.g. E. Courant, A Course in Mathematical Analysis (1905; trans. by E. R. Hedrick). For the methods involving finite differences, see references under DIFFERENCES, CALCULUS OF.

In an optimal point, momenta are illustrated see W. P. Elderton, Frequency-Curves and Correlation (1906); as to the formulae of § 82, see also Biometrika, v. 450. For mechanical methods of calculating areas and moments see CALCULATING MACHINES.

MENAWI, a chain of islands in the Dutch East Indies, off the west coast of Sumatra between 5° and 9° 30' S. The two largest islands, Mentaw and Mentaw, of which the majority lie close to or between the four largest—Siberut, Siburan and Sipora, North Pageh and South Pageh. The two last (also called Pagi or Poggy) are sometimes termed the Nassau Islands. The total land area is 1224 sq. m. The islands are included in the administration of Padang, Sumatra. They are apparently volcanic. Coral reefs lie off the coasts and render them difficult of access. The natives in language and customs present affinities with some Polynesians, and have been held to be a survival of the eastward immigration of people of Caucidian origin, in which they were probably connected with the etymology of the name, from the root mon, seen, in Lat. monere, to advise, monitor, adviser.

The New English Dictionary points out that the transferred use is due less to Homer's Odyssey than to Fénélon's Télémaque, in which Mentor is somewhat a prominent character.

MENTOR OF RHODES, brother of Memnon (vr.), a Greek condotiere who appears first in the service of the rebellious satrap Artabanus of Phrygia in 353. When Artabanus had rebelled a second time and was in 355 forced to flee with Memnon into Macedonia, Mentor entered the service of the Egyptian king of Thebes, and was sent by Memnon with a body of Greek mercenaries to support the rebellious king T Ebni (Tanbit) of Aegypt against Artaxerxes III. But Tennes and Mentor betrayed the besieged town to the Persians (344 b.c.). Tennes was killed after his treason, but Mentor gained the favour of the king. It was due largely to him that Egypt was conquered in 343 (Diod. xvi. 45 sqq.). He now closely allied himself with the eunuch Bagoas (vr.), the all-powerful vizier of Artaxerxes III. He was appointed general in Asia Minor, and with the help of Artabazus and Memnon, whose pardon and recall he obtained from Artaxerxes III, he captured Cyzicus (334). His name is famous among them was Hermias of Atarneus, the protector of Aristotle, who had become master of some towns of Aeolis and Troas. By treachery he made him prisoner and occupied his town (342 b.c.); Hermias was executed by order of the king (Diod. xvi. 52; Polyaen. vi. 48; pseudo-Arist. Oecon. ii. 27; Strabo xiii. 610; Didymus' commentary on Demosthenes Phil. 4, 6; cf. Diog. Laërt. vi. 9). Shortly afterwards Mentor died, and was succeeded by his brother Memnon. His son Thymondas commanded in the naval war against Alexander and at Issus (Arrian ii. 2: 15; 20). (Ed. M.)

MENZEL, ADOLPH FRITZHEIM ERDMANN VON (1815-1905), German artist, was born at Breslau on the 8th of December 1815. His father was at the head of a school for girls, and intended to educate his son as a professor; but he would not thwart his taste for art. Left an orphan in 1832, Menzel had to maintain his family. In 1835 Sachse of Berlin published his first work, an album of pen-and-ink drawings reproduced on stone, to illustrate Goethe's little poem, "Künstlers Erdenwallen." He executed lithographs in the same manner to illustrate Deutschlands Religionsgeschichte, etc. (1837), pp. 543-586; "The Five Senses" and "The Prayer," as well as diplomas for various corporations and societies. From 1839 to 1842 he produced 400 drawings, reviving at the same time the technique of engraving on wood, to illustrate Geschichte Friedrich des Grossen ("History of Frederick the Great") by Franz Kugler. He subsequently brought out Friedrich des Grossen Arme in ihrer Uniformirung ("The Uniforms of the Army under Frederick the Great"), Soldaten Friedrich des Grossen ("The Soldiers of Frederick the Great"); and finally, by
order of the king Frederick William IV., he illustrated the works of Frederick the Great, Illustrationen zu den Werken Friedrich des Grossen (1843–1849). By these works Menzel established his claim to be considered one of the first, if not actually the first, of the illustrators of his day in his own line. Meanwhile Menzel had set himself to study unaided the art of painting, and he soon produced a great number and variety of pictures, always showing keen observation and honest workmanship—subjects dealing with the life and achievements of Frederick the Great, and scenes of everyday life, such as "In the Tuileries," "The Ball Supper," and "At Confession." Among the most important of these works are "The Forge" (1875) and "The Market-place at Verona." Invited to paint "The Coronation of William I. at Koenigsberg," he produced an exact representation of the ceremony without regard to the traditions of official painting. Menzel died at Berlin on the 9th of February 1903. In Germany he received many honours, and was the first painter to be given the order of the Black Eagle.

MENZEL, WOLFGANG (1780–1875), German poet, critic and literary historian, was born on the 21st of June 1780, at Waldenburg in Silesia, studied at Breslau, Jena and Bonn, and after living for some time in Aarau and Heidelberg finally settled in Stuttgart, where, from 1830 to 1838, he had a seat in the Württemberg Diet. His first work, a clever and original volume of poems, entitled Streichverse (Heidelberg, 1823), was followed in 1824–1825 by a popular Geschichte der Deutschen in three volumes and in 1829 and 1836 by Rückblicke and Narcissus, the dramatized fairy tales from the German and French chieftains. In 1832 he published the romance of Furor, a lively picture of the period of the Thirty Years' War; his other writings include Geschichte Europas, 1789–1815 (2 vols. Stuttgart, 1853), and histories of the German War of 1866 and of the Franco-German War of 1870–71. From 1826 to 1848 Menzel edited a "Literaturblatt" in connexion with the Morgenblatt; in the latter year he transferred his allegiance from the Liberal to the Conservative party, and in 1852 his "Literaturblatt" was revived in that interest. In 1866 his political sympathies again changed, and he opposed the "particularism" of the Prussian " Junkers" and the anti-unionism of south Germany. He died on the 23rd of April 1873 at Stuttgart. His library of 18,000 volumes was afterwards acquired for the university of Strassburg.

MENZELINSK, a town of eastern Russia, in the government of Ufa, 144 m. N.W. of the town of Ufa, and 10 m. from the left bank of the Kama. Pop. (1897), 7,542. Its fair is one of the most important in the southern Ural region for cattle, hides, furs, grain, tea, manufactured articles, crockery, &c., and is sold to the annual value of £500,000. The town was founded in 1534. 

MEPHISTOPHELES, 1 in the Faust legend of the name, the name of the character of the Prussian "Junker" and the anti-unionism of south Germany. He died on the 23rd of April 1873 at Stuttgart. His library of 18,000 volumes was afterwards acquired for the university of Strassburg.

MEPPEL, a town in the province of Drente, Holland, 161 m. by rail N. by E. of Zwolle. Pop. (1903), 16,470. It is favourably situated at the confluence of a number of canals and rivers which communicate hence with the Zuider Zee by the Meppeler Diep, and rose rapidly into prominence in the 19th century. The chief business is in butter, eggs, cattle and pigs, while bleaching, dyeing and shipbuilding are also carried on here.

MEQUINEZ (the Spanish form of the Arabic Mikanas), a city of Morocco, situated 1600 ft. above the sea, about 70 m. from the west coast and 35 m. W.S.W. of Fez, on the road to Rabat, in 33° 56' N., 5° 50' W. The town wall with its four-cornered towers is pierced by nine gates, one, the Bâb Badain, with fine tile-work. A lower wall of wider circuit protects the luxuriant gardens in the outsides. Mequinez at a distance appears a city of palaces, but it possesses few buildings of any note except the palace and the mosque of Mulai Ismail, which serves as the royal burying-place. The palace, founded in 1634, was described in 1721 by John Windus in his Journey to Mequinez (London 1825) as "about 4 m. in circumference, the whole building exceeding massy, and the walls in every part very thick; the outward one about a mile long and 25 ft. thick." The interior is composed of oblong court-yards surrounded by buildings and arcades. These buildings are more or less square with pyramidal roofs ornamented outside with green glazed tiles, and inside with and topheli, latt (Faust, ed. 1886, i. 25), which is certainly supported by the fact that almost all the names of devils in the magic-books of the 16th century are derived from the Hebrew.

1 In the Faustbuch of 1587 it is spelt Mephistophels; by Marlowe Mephistepheles; by Shakespeare (Merry Wives of Windsor, Act I.) Mephostepheles. The form Mephistopheles adopted by Goethe first appears in the version des Christlich Meinenden, c. 1712.

2 Alles was entschied ist wert dass es zu Grunde geht.
MERAN—MERCANTILE SYSTEM

The walls are tiled to a height of 4 or 5 ft., and above they are finished in plaster, whitewashed or carved into filigree work. The population numbers being between thirty and forty thousand. Idriß, writing in A.D. 1100, calls the place Takarat, and describes it as an ordinary citadel, from which the town gradually developed, taking its name from theMessaging Berbers.

MERAN, the chief town of the administrative district of the same name, an Austrian province of the Tirol, 20 m. by rail N.W. of Botzen, on the Brenner line, while the Vintschau railway connects it with Mals, 37 m. N.W. It is the chief town in the upper Adige valley, a region which bears the special name of the Vintschau, and is on the high road either to Landeck and the Lower Engadine by the Reschen Scheideck Pass (4902 ft.), or more directly to the Lower Engadine by the Münster valley and the Ofen Pass (7071 ft.). In 1500 Meran had 9284 inhabitants (or, with the neighbouring villages of Untermals and Obermals, 13,201), mainly German-speaking and Romanist. The town is picturesquely situated, at a height of 565 ft., at the foot of the vine-clad Kührbelberg, and on the right bank of the Passer River, just above its junction with the Adige or Etsch. Meran proper consists mainly of one long narrow street, the Laubengasse, flanked by covered arcades, but the name is often used to include several adjacent villages, Untermals and Obermals being on the left bank of the Passer, while Gratsch is on its right bank and north-west of the main town. The most noteworthy buildings are the parish church (14th to 15th centuries) and the old residence (15th century) of the counts of the Tirol. Meran is best known as a much-frequented resort for invalid patients, with one of the most beautiful views of the purity of the air and the comparative immunity of the place from wind and rain in the winter. It is also visited in spring for the wehy cure and in autumn for the grape cure.

The north-west, on the Kührbelberg, is the half-mined castle of Tirol (2066 ft.), the original seat of the family which gave its name to the county. Meran may have been built on the site of a Roman settlement, but is first mentioned in 857. From the 12th century to about 1426 it was the capital of the ever-extending land named after it Tirol, but then had to give way to Innsbruck, while the building of the Brenner railway (1864-1866) and the rise of Botzen have decreased its commercial importance.

(W. A. B. C.)

MERBECK (or MARBECK), JOHN (d. c. 1585), English theological writer and musician, was organist of St. George's, Windsor, about 1540. Four years later he was convicted of heresy and sentenced to the stake, but received a pardon owing to the intervention of Gardiner, bishop of Winchester, though Gardiner had himself censured Merbeck for compiling an English Concordance of the Bible. This work, the first of its kind in English, was published in 1550 with a dedication to Edward VI. In the same year Merbeck published his annotated Book of Common Prayer, intended to provide for musical uniformity in the use of the First Prayer Book of Edward VI., which was several times reprinted in the 16th century. Merbeck wrote several devotional and controversial works of a strongly Calvinistic character, and a number of his musical compositions are preserved in manuscript in the British Museum, and at Oxford and Cambridge. He died, probably while still organist at Windsor, about 1585. His son, ROGER MERBECK (1536-1605), a noted classical scholar, was appointed public orator in the university of Oxford in 1564, and in 1565 became a canon of Christ Church and was elected provost of Oriel; he left Oxford on account of an unfortunate marriage, and took to medicine as a profession, becoming the first registrar of the College of Physicians in London, and chief physician to Queen Elizabeth.

MERCADIER (d. 1200), French warrior of the 12th century, and chief of freebooters in the service of Richard I. of England. In 1183 he operated for Richard, then duke of Aquitaine, in the Limousin and the Angoumois, taking castles and laying waste the country. We know nothing of him during the ten years 1184-1194, but after Richard's return from Palestine, Mercadier accompanied him everywhere, travelling and fighting by his side. Richard eulogized Mercadier's exploits in his letters, and gave him the estates left by Adémar de Binauc, who died without heirs about 1190. During the various wars between Richard and Philip Augustus of France, Mercadier fought successively in Berry, Normandy, Flanders and Brittany. When Richard was mortally wounded at the siege of Châlus in March 1199, Mercadier avenged him by hanging the defenders of the château and slaying the crossbowmen who had shot the king. Mercadier then entered the service of John, king of Flanders. After Easter Monday, the 10th of April 1200, he was assassinated while on a visit to Bordeaux to pay his respects to Eleanor of Aquitaine, who was bringing from Spain Blanche of Castile. His murderer was an agent of Brandin, another freebooter in the service of John.

See Geraud, Mercadier, in Bibliothèque de l'École des Chartes, 1st series, t. iii, pp. 417-443.

MERCANTILE (or COMMERCIAL) AGENCIES, the name given in America to organizations designed to collect, record and distribute to regular clients information relative to the standing of important commercial firms in different countries. In Europe, various trade protective societies, composed of merchants and tradesmen, are formed for the promotion of trade, and members exchange information regarding the standing of business houses. These societies have their origin in the associations formed in the middle of the 19th century for the purpose of disseminating information regarding bankruptcies, assignments and bills of sale. The mercantile agency in the United States is a much more comprehensive organization. It came into existence after the financial crisis of 1837. Trade in the United States had at that time reached a point where it was necessary for the merchants to know the credit standing of their correspondents, and to have such information, it was found necessary to organize mercantile agencies, analogous to the standing of many business men seeking credit. Undoubtedly the severity of the collapse of 1837 was due in part to the insufficiency of this information. New York merchants, who had suffered so severely, determined to organize a head-quarters where reports regarding the standing of customers could be exchanged. Lewis Tappan (1788-1873), founder of the Journal of Commerce (1828) and a prominent anti-slavery leader, undertook the work, and established in New York, in 1841, the Mercantile Agency, the first organization of its kind. The Mercantile System, the name given to the economic policy which developed in Europe at the close of the middle ages. The doctrine of the mercantile system, stated in its most extreme form, made wealth and money identical, and regarded it therefore as the great object of a community so to conduct its dealings with other nations as to attract to itself the largest possible share of the precious metals. Each country's interest was to export the utmost possible quantity of its own manufactures and to import as little as possible of those of other countries, receiving the difference of the two values in gold and silver. This difference is called the balance of trade, and the balance is favourable when more money is received than is paid. Governments might resort to all available expedients—prohibition of, or high duties on, the importation of foreign wares, bounties on the export of home manufactures, restrictions on the export of the precious metals—for the purpose of securing such a balance.

But this statement of the doctrine, though current in textbooks, does not represent correctly the views of all who belonged to the mercantile school. Many members of that school were much too clear-sighted to entertain the belief that wealth consists exclusively of gold and silver. The mercantilists might be described, as W. G. F. Roscher remarked, not by any definite economic theorem which they held in common, but by a set of theorectic tendencies, commonly found in combination, though severely prevailing in different degrees in different minds. The underlying principles may be enumerated as follows: (1) the importance of possessing a large amount of the precious metals; (2) an exaltation (a) of foreign trade over domestic, and (b) of the industry which works up materials over that which provides them; (3) the value of a dense population as an element of national strength; and (4) the employment of state action in furthering artificially the attainment of the ends proposed.
The discoveries in the New World had led to a large development of the European currencies. The old feudal economy, founded principally on dealings in kind, had given way before the new "money economy," and the dimensions of the latter were everywhere expanding. Circulation was becoming more rapid, distant communications more frequent, city life and movable property more important. The mercantilists were impressed by the fact that money is wealth sunt generis, that it is at all times in unitic demand, and that it put into the hands of its possessor the power of acquiring all other commodities. The period, again, was marked by the formation of great states, with powerful governments at their head. These governments required men and money for the maintenance of permanent armies, which, especially for the religious and Italian wars, were kept up on a great scale. Court expenses, too, were more lavish than ever before, and a larger number of civil officials was employed. The royal domains and dues were insufficient to meet these requirements, and taxation grew with the demands of the monarchies.

State men saw that for their own power and wealth to flourish. But manufactures make possible a denser population and a higher total value of exports than agriculture; they open a less limited and more promptly extensible field to enterprise. Hence they became the object of special governmental favour and patronage, whilst agriculture fell comparatively into the background.

The growth of manufactures reacted on commerce, to which a new and mighty arena had been opened by the establishment of colonies. These were then viewed simply as estates to be worked for the advantage of the mother countries, and the aim of statesmen was to make the colonial trade a new source of plunder. Each nation, as we have said, worked for its own power, and the greater ones for predominance, they entered into a competitive struggle in the economic no less than in the political field, success in the former being indeed, by the rulers, regarded as instrumental to pre-eminence in the latter. A national economic interest came to exist, of which the government made itself the representative head.

States became a sort of artificial hothouse for the rearing of urban industries. Production was subjected to systematic regulation, with the object of securing the goodness and cheapness of the exported articles, and so maintaining the place of the nation in foreign markets. The industrial control was exercised, in part directly by the state, but largely also through privileged corporations and trading companies. High duties on imports were resorted to, at first perhaps mainly for revenue, but afterwards in the interest of national production.

Commercial treaties were a principal object of diplomacy, the end in view being to exclude the competition of other nations in foreign markets, whilst in the home market as little room as possible was given for the introduction of anything but raw materials from abroad. The colonies were prohibited from trading with other European nations than the parent country, to which they supplied either the precious metals or raw produce purchased with home manufactures.

That the efforts of governments for the furtherance of manufactures and commerce under the mercantile system were really effective towards that end is admitted by Adam Smith, and cannot reasonably be doubted, though doctrinaire free-traders have often denied it. Technical skill must have been promoted by their encouragements; whilst new forms of national production were fostered by attracting workmen from other countries, and by lightening the burden of taxation on struggling industries. Communication and transport by land and sea were more rapidly improved; and the social dignity of the industrial professions was enhanced relatively to that of the classes before exclusively dominant.

The foundation of the mercantile system was at the time when it took its rise inspired by the situation of the European nations.

Such a policy had been already in some degree practised in the 14th and 15th centuries, thus preceding any formal exposition or defence of its speculative basis. At the commencement of the 16th century it began to exercise a widely extended influence. Charles V. adopted it, and his example contributed much to its predominance. Henry VIII. and Elizabeth conformed their measures to it. The leading states soon entered on a universal competition for manufacturing and commercial preponderance. Through almost the whole of the 17th century the prize, so far as commerce was concerned, remained in the possession of Holland, Italy having lost her former ascendancy by the opening of the new maritime routes, and Spain and Germany being depressed by protracted wars and internal dissensions. The admiring envy of Holland felt by English politicians and economists appears in the writings of Raleigh, Mun, Child and Temple. Cromwell, by his Navigation Act, which destroyed the carrying trade of Holland and founded the English empire of the sea, and Colbert, by his whole economic policy, domestic and international, were the chief practical representatives of the mercantile system.

MERCAPTANS (Thio-alcohols), organic chemical compounds of the type RSH (R = an alkyl group). The name is derived from mercurium capsans, in allusion to the fact that these compounds react readily with mercuric oxide to form crystalline mercury derivatives. The mercaptans may be prepared by the action of the alkyl halides on an alcoholic solution of potassium hydroxysulphide; by the reduction of the sulpho-chlorides, e.g. CH3H2SOCl (chlorides of sulphonic acids), by heating the salts of esters of sulphuric acid with potassium hydroxysulphide, and by heating the alcohols with phosphorus pentasulphide. They are generally colourless liquids, which boil at 36-2° C. and which have a characteristic offensive smell. On oxidation by nitric acid they yield sulphonic acids. They combine with aldehydes and ketones, with elimination of water and formation of mercaptals and mercaptols. (See Sulphonal.)

Methyl mercaptan, CH3SH, is a liquid which boils at 5-8° C. (252 mm.), and forms a crystalline hydrate with water. Ethyl mercaptan, C2H5SH, is a colourless liquid which boils at 39-6° C. It is used commercially in the preparation of sulphon (gs.). The mercury salt, Hg(SCH3)2, crystallizes from alcohol in plates. When heated with alcohol to 190° C. it decomposes into mercury and ethyl mercaptal.

MERCATOR, GERARDUS [latinized form of GERHARD KREMER] (1512-1594), Flemish mathematician and geographer, was born at Rupelemonde, in Flanders, on the 9th of March 1512. Having studied at Bois-le-Duc and Louvain (where he matriculated on the 29th of August 1530, and became licentiate in October 1532), he met Gemma Frisius, a pupil of Aplan of Ingolstadt, who at the request of the emperor Charles V. had settled in Louvain. From Frisius young Kremer derived much of his inclination to cartography and scientific geography. In 1534 he founded his geographical establishment at Louvain; in 1537 he published his earliest known map, now lost (Terra sanctae descriptio). In 1537-1540 he executed his famous survey and map of Flanders (Exaltissima Flandriae descriptio), of which two copies exist in the Musée Plantin, Antwerp. At the order of Charles V. Mercator made a complete set of instruments of observation for the emperor's campaigns: when these were destroyed by fire, in 1546, another set was ordered of the same maker. In 1538 appeared Mercator's map of the world in (north and south) hemispheres, which was rediscovered in 1878 in New York; this work shows Ptolemy's influence still dominant over Mercatorian cartography. In 1541 he issued the celebrated terrestrial globe, which he dedicated to Nicolas Perrenot, father of Cardinal Granvelle: this was accompanied by his Libelli de usu globi, which is said to have been presented to Charles V. In 1552 or 1553 earthly globe followed. Mercator early began to incline towards Protestantism; in 1553 he had retired for a time from Louvain to Antwerp, partly to avoid inquiry into his religious beliefs; in 1544 he was arrested and prosecuted for heresy, but escaped serious consequences (two of the forty-two arrested with him were burnt, one beheaded, two buried alive). He now thought seriously of emigrating; and when in 1552 Cassander, ordered by the duke of Juliers, Cleves and Berg to organize a university at Duisburg, offered Mercator the chair of cosmography the offer was accepted. The organization of the
university was adjourned, and never completed in Mercator's lifetime; but he now became cosmographer to the duke and permanently settled on the German soil to which many of his ancestors and relatives had belonged. Soon after this, however, he paid a visit to Charles V. at Brussels, and presented the emperor with a cosmos, a celestial sphere enclosing a terrestrial, together with an explanatory Declaratio: this work marks an era in the observation of longitude by magnetic declination, perfected by Halley. Charles rewarded the author with the title of imperatorit domusiticus (Hofrat in the epitaph at Duisburg). In 1534 Mercator published his great map of Europe in six sheets, three of which had already been prepared in 1533 at Louvain; a copy of this was rediscovered at Breslau in 1889. Herein, though still greatly under Ptolemy's influence, Mercator begins to emancipate himself; thus Ptolemy's 62° for the length of the Mediterranean, reduced to 58° in the globe of 1541, he now cuts down to 53°. On the 28th of October 1556 he observed an eclipse at Duisburg; in 1563 he surveyed Lorraine, at the request of Duke Charles, and completed a map of the same (Lotharingiae descriptio); but it is uncertain if this was ever published. In 1564 he engraved William Camden's map of Britain; in 1567 he brought out his Chronologia, hoc est temporum demonstratio ab initio mundi usque ad annum domini 1568, ex eclipsiis et observationibus astronomicae. In the same year was published his memorable planisphere for use in navigation, the first map on "Mercator's projection," with the parallels and meridians at right angles (Nova et acuta orbis terrae descriptio ad usum navigantium accommodata). Improvements were introduced in this projection by Edward Wright in 1590; the more general use of it dates from about 1630, and largely came about through Dugard's support. In 1578 Mercator issued his second edition of his map of Europe; in 1587 appeared his Tabulae geographicae ad mentem Ptolemaei restitutae et emendatae; and in 1585 the first part (containing Germany, France and Belgium) of the Atlas, sive cosmographicae mediationes de fabrica mundi, in which he planned to crown his work by uniting in one volume his various detailed maps, so as to form a general description of the globe. In 1585 he adapted his Europe to the Atlas; in 1587, with the help of his son Rumold, he added to the same a world-map (Orbis terrarum compendiosa descriptio), followed in 1599 by a second series of detailed maps (Italy, Slavonia, Grece and Carthago). In the map of the regions and other plans in this undertaking, mostly begun by Gerard, were finished by Rumold; they include Iceland and the Polar regions, the British Isles (dedicated to Queen Elizabeth), the Scandinavian countries (dedicated to Henr. Ranzovius), Prussia and Livonia, Russia, Lithuania, Transylvania, the Crimea, Asia, Africa and America (in the last Michael Mercator, in Asia and Africa Gerard Mercator the younger, assisted). The designs are accompanied by cosmographical and other dissertations, some of the theological views in which were condemned as heretical (see the Duisburg edition of 1594, folio). In 1592 Mercator published, two years after his first apoplectic stroke, a Harmonia evangeliorum. He died on the 5th of December 1594, and was buried in St Saviour's church, Duisburg. Besides his famous projection, he did excellent service with Ortelsius in helping to free the geography of the 16th century from the tyranny of Ptolemy; his map and instrument work is noteworthy for its delicate precision and admirable execution in detail.

**MERCENARY** (Lat. mercenarius, from merces, reward, gain), one who serves or acts solely for motives of personal gain, particularly a soldier who offers himself for service in any army which may hire him. The name is sometimes used as a term of reproach by nations who raise their armies by conscription, of armies raised by voluntary enlistment whose members are paid a more or less living wage.

**MERCER** (through Fr. merier, from popular Lat. mercarius, a dealer, merx, merces, merchandise), a dealer in the more costly textiles, especially in silks and velvets. The word formerly had a wider meaning. Mercery, according to W. Herbert (History of Parchment and Paper, 1869), means the "manufacture of parchment and leather by the methods of the 'merciers.'"

**MERCERIZING**, the term applied to a process, discovered in 1844 by John Mercer, a Lancashire calico printer, which consists in treating cotton (and to a limited extent other plant fibres) with strong caustic soda or certain other reagents, whereby morphological and chemical changes are brought about in the fibre. Thus, if a piece of bleached calico be immersed in caustic soda of 50° Tt. strength (sp. gr. 1.25), it rapidly changes in appearance, becoming stiff and translucent, but when taken out and well washed in running water it loses these properties and apparently reverts to its original condition. On closer examination, however, the fabric is found to have shrunk considerably both in length and breadth, so as to render the texture quite different in appearance to that of the original calico; it is also considerably stronger, and if dyed in the same bath along with some of the untreated fabric is found to have acquired a greatly increased affinity for colouring matters. This peculiar action is not restricted to caustic soda, similar effects being observed with sulphuric acid of 105° Tt., nitric acid of 5g° Tt., zinc chloride solution of 145° Tt., and other reagents. Mercer assumed that a definite compound, corresponding to the formula C,H,0,Na, is formed when the cotton is steeped in caustic soda, and that this is decomposed by subsequent washing with water into a hydrated cellulose C,2H,0,Na,H,0, which would account for the fact that in the air-dried condition mercerized cotton retains about 5% more hygroscopic moisture than ordinary cotton. This view is strengthened by the observation that when cotton is immersed in nitric acid of 85° Tt. it acquires similar properties to cotton treated with caustic soda. If, after immersion in the nitric acid, it is squeezed and then dried (without washing) in a vacuum over burnt lime, it is found to have formed a compound which corresponds approximately to the formula C,H,0,Na,H,0, which is decomposed by water into free nitric acid and a hydrated cellulose.

When viewed under the microscope, mercerized cotton is seen to have undergone considerable morphological changes, inasmuch as the lumen or central cavity is much reduced in size, while the fibre has lost its characteristic band-shaped appearance and becomes rounded.

In Mercer's time the process, which he himself termed "sodaizing" or "fulling," never acquired any degree of com-
Material success, partly on account of the expense of the caustic soda required, but mainly on account of the great shrinkage (20 to 25%) which took place in the cloth. An important application of the process in calico printing for the production of permanent crimp or "crépon" effects, which was originally devised by Mercer, was revived in 1860-1861 and is still largely practised by calico printers (see Textile Printing). Another application, also dependent upon the shrinking action of caustic soda on cotton, was patented in 1884 by Depouilly, and it is this process which has received its object the process of crepe-goody. The machine consists of a series of rollers consisting of wool and cotton or silk and cotton. In the manufacture of such goods, cotton binding threads are introduced at definite intervals in the warp or weft, or both, and the piece is passed through cold caustic soda, washed, passed through dilute sulphuric acid, and washed again till neutral. The cotton contracts under the influence of the caustic soda, while both wool and silk remain unaffected, and the desired crimped or puckered effect is thus obtained.

By far the most important application of the mercerizing process is that by which a permanent lustre is imparted to cotton goods; this was discovered in 1889 by H.A. Lowe, who took out a patent for his process in that year, this being supplemented by a further patent in 1890. Since Lowe's invention did not receive sufficient encouragement, he allowed his patents to lapse and the process thus became public property. It was not until 1895, when Messrs Thomas & Prevost patented Lowe's invention, that actual interest was aroused in the new product and the process became a practical success. Their patent was subsequently annulled on the ground of having been anticipated.

The production of a permanent lustre on cotton by mercerizing is a simple process, and may be effected in two ways. According to the first method, the cotton is treated in a stretched condition with strong caustic soda, and is then washed, while still stretched, in water. After the washing has been continued for a short time, the cloth is removed from the bath, and found that the cloth has acquired a permanent lustre or gloss similar in appearance to that of a spun silk though not so pronounced. According to the second method, which constitutes but a slight modification of the first, the cotton is immersed in caustic soda of the strength required for mercerizing, and is then taken out, stretched slightly beyond its original length, and then washed until the tension slackens.

Not all classes of cotton are equally suited for being mercerized. Thus, in the case of yarns the most brilliant lustre is always obtained on twofold or multifold yarns spun from long-stapled cotton (Egyptian or Sea Island). Single yarns made from the same quality of cotton, but produced by the process, and are consequently seldom mercerized; and the same applies to twofold yarns made from ordinary American cotton. In piece-goods, likewise, a certain amount of slackening is necessary, so that it is best if the yarn used for weaving should be twofold. In the great majority of cases, the mercerizing of cotton, whether it be in the yarn or in the piece, is done before bleaching, but sometimes it is found necessary to do so after bleaching, even a few hours after dyeing. The strength of the caustic soda employed in practice is generally between 55 and 60° T. The temperature of the caustic soda has a material influence on its action on the cotton fibre, very much stronger solutions being required to produce the same effect at elevated temperatures than at the ordinary temperature, while, on the contrary, by lowering the temperature it is possible to obtain a great lustre with considerably weaker liquors.

Cotton yarn may be mercerized either in the hank or in the warp, and a great number of machines have been patented and constructed for the purpose. The simplest form of machine for hank mercerizing consists of two or more long steel rolls, on which the hanks are placed and spread out evenly. The upper roller, the bearings of which run in a slotted groove, is then raised by mechanical means, until the hanks are taut. Caustic soda of 60° T. is next applied, and the upper roller is caused to revolve slowly, the hanks acting as a band and causing the lower roller to revolve simultaneously. After about a minute the caustic soda liquor is pumped back into the bath, and the hanks are then washed until they slacken, when they are taken off and rinsed, first in dilute sulphuric acid (to neutralize the alkali and facilitate washing), and then in water till neutral. The hanks are then bleached in the ordinary manner, after which the slackness is again brought about in the lustre by these operations. Cotton warps are usually mercerized on a machine similar in construction to a four blade beaming machine (see Textile), but the hanks are not passed through the beaming process, and the squeezer at each end of the first box with a double nip (three rollers). The first box contains caustic soda, the second water, the third dilute sulphuric acid, and the fourth water.

For the continuous mercerizing of cotton in the piece much more complicated and expensive machinery is required than for yarn, since it is necessary to prevent contraction in both length and breadth, and to prevent the mercerizing from being done on most common use, it is most convenient to be constructed on the same principle as the stentering machine used in stretching pieces after bleaching, dyeing or printing, and consists of two endless chains carried at either end by sprocket wheels. The chains carry hanks in slotted grooves on the horizontal frame of the machine, which is about 40 ft. in length. The hanks close automatically and grip the cloth on either side as it is placed in the machine. The hanks are then passed through the caustic soda. The stretching of the piece begins immediately on entering the machine, the two rows of clips being caused to diverge by setting the slotted grooves in such a manner that when the piece has travelled one third of the length of the machine it is stretched slightly beyond its original width. At this point the piece meets with a spray of water, which is thrown on by means of a second set of clips, and in consequence of the tension being relieved, the mercerizing is effected. When the piece arrives at the end of the machine the clips open automatically and release it. Thence it passes through a box containing dilute sulphuric acid, and then through a second box where washing with water is effected.

In most large works the caustic soda washings, which were formerly run to waste or were partly used up for bleaching, are sprayed on in multiple effect evaporators to 90° T., and the solutions is used over again for mercerizing.

Cotton mercerized under tension has not as much affinity for colouring matters as cotton mercerized without tension, and although it performs satisfactorily for dyeing of hygroscopic substances, which are not acted on enough by the tension to greatly change their condition is greater than in the case of ordinary untreated cotton, it is not so great as that held by cotton which has been mercerized without tension. By drying cotton which has been mercerized with tension at temperatures above 100° C. its affinity for colouring matters is materially decreased.

The cause of the lustre produced by mercerizing has been variously explained in some cases, assisting valuable works as well as other methods. A paper on the subject. When viewed under the microscope by reflected light, the irregularly twisted band-shaped cotton fibre is seen to exhibit a strong lustre at those points from which the light is reflected from the surface. Cotton mercerized without tension shows a similar appearance. In the yarn or piece the lustre is not apparent, because the innumerable reflecting surfaces disperse the light in all directions. If, however, the cotton has been mercerized under tension, being passed through the caustic soda, it is stretched and is set in this condition by the washing. Thus in the finished product a large proportion of the rounded fibres are laid parallel to each other, as in the case of spun silk, and the lustre inherent to the fibre becomes visible to the naked eye.

See The Life and Labours of John Mercer, by E.A. Parnell (Longmans Green & Co.); Die Mercerisation der Baumwolle, by Paul Gardner (Julius Springer, Berlin); Mercerisation, by The Dyer and Calico Printer (Heywood & Co.).

MERCHANT (O. Fr. merochent, modern marchand; from Lat. mercari, to trade, mercx, goods, merchandise), a trader, one who buys and sells goods for profit. The term is now usually confined to a wholesale dealer or one who trades on an extended scale with foreign countries.

MERCIA, one of the kingdoms of Anglo-Saxon England. The original kingdom seems to have lain in the upper basin of the Trent, comprising the greater part of the counties of Staffordshire, the northern parts of Warwickshire and Leicestershire, and the southern part of Nottinghamshire. The name (Merc) seems to denote men of the March, and presumably was first applied when this district bordered upon the Welsh. In later times Mercia successively absorbed all the other territories between the Humber and the Thames except East Anglia, and some districts even beyond the Thames.

The origin of the kingdom is obscure. The royal family, according to Felix, Life of St Guthlac (Anglo-Saxon version), were called Icelings. Icel, their ancestor, may have been the founder of the kingdom, but nothing is known of him. The family, however, claimed descent from the ancient kings of Angle (cf. Offa I. and Wermund). The first Mercian king of whom we have any record was Cerf, who apparently reigned about the beginning of the 7th century, and whose wife Coenburg married Edwin, king of Deira. During Edwin's reign Mercia was subject to his supremacy, though it may have been governed throughout by princes of its own royal family. Its first prominent appearance in English history may be dated in the year 633, when the Mercian prince Penda joined the king Ceawlin in overthrowing Edwin. According to the Saxon Chronicle, Penda began to reign in 626, and fought against the
West Saxons at Cirencester in 628. In the Mercian regnal tables, however, he is assigned a reign of only twenty-one years, which, as his death took place in 654 or 655, would give 634 as the date of his accession, presumably on the overthrow of Edwin, or perhaps on that of Ceawulda. During the reign of Oswald Penda clearly reigned under the suzerainty of that king. In 642, however, Oswald was slain by Penda in a battle at a place called Maserfeld, which has not been identified with certainty. During the early part of Oswiu’s reign the Northumbrian kingdom was repeatedly invaded and ravaged by the Mercians, and on one occasion (before 651) Penda besieged and almost captured the Northumbrian royal castle at Bambergh. At the same time he extended his power, and in other parts of his kingdom and expelled from the throne of Wessex Coenwulf, who had divorced his sister. Indeed, at this time nearly all the English kingdoms must have acknowledged his supremacy. The kingdom of Middle Anglia, which appears to have included the counties of Northampton, Rutland, Huntingdon, and parts of Bedfordshire, Cambridgeshire, Leicestershire and Lincolnshire, was formed into a dependent principality under his son Peada. At this time also the territory corresponding to the modern counties of Cheshire, Shropshire and Herefordshire seems to have been occupied. The last of these counties to be invaded by the Mercians, and possibly to have been under the government of another son of Penda, named Merewald. In 654 or 655 Penda again invaded Northumbria, with a huge army divided into thirty *legiones*, each under a royal prince, among whom were Ethelhere, king of East Anglia, and several Welsh kings. He was defeated and slain, however, by Oswiu, at a river called the Winwaed. Mercia then came again under Northumbrian rule. Peada, the eldest son of Penda, was allowed to govern the part south of the Trent, while north Mercia was put in charge of Northumbrian officials. Penda, although he did not prohibit the preaching of Christianity, had remained a heathen to the end of his life. His death was followed by the conversion of his kingdom. Peada had embraced Christianity on his marriage with a daughter of Oswiu, and under him the first Mercian bishopric was founded. Shortly afterwards Peada was murdered; but in 658 the Mercians rose under his younger brother Wulfhere and threw off the Northumbrian supremacy.

Wulfhere seems to have been a vigorous ruler, for he extended the power of Mercia as far as it had reached in the days of his father, and even farther. According to the Chronicle he invaded Wessex as far as Ashdown in Berkshire in the year 661. At the same time he conquered the Isle of Wight, which he gave to Ethelwalh, king of Sussex. Between the years 661 and 665 he was defeated by the Northumbrian king Egfrith and had to give up Lindsey. In 675 he again fought with the West Saxons under Aescwine, and shortly afterwards died. His brother Æthelred, who succeeded him, invaded Kent in the following year, and in 679 fought a battle on the Trent against Egfrith, by which he recovered Lindsey. After this, however, we hear little of Mercian interference with the other kingdoms for some time; and since it is clear that during the last 15 years of the 7th century Wessex, Essex, Sussex and Kent were frequently involved in strife, it seems likely that the Mercian king had somewhat lost hold over the south of England. In 704 Æthelred resigned the crown and became a monk, leaving his kingdom to Coenred, the son of Wulfhere. Coenred also abdicated five years later and went to Rome. Coenred, the son of Æthelred, who succeeded, fought against the West Saxon king Ine in 715. On his death in the following year Æthelbald, a distant relative, came to the throne. He reigned for nine years over all the kingdom south of the Humber. He reigned for 41 years. After his murder in 757 the Mercian throne was held for a short time by Beornred. He was expelled the same year by Offa, who soon restored the power of Mercia, which seems to have suffered some diminution during the later years of Æthelbald. Offa’s policy was apparently the extinction of the dependent kingdoms. In his reign the dynasties of Kent, Sussex and the Hwiccæ seem to have disappeared, or at all events to have given up the kingly title. In 787 he associated his son Egfrith with him in the kingdom, and after his death (796) Egfrith reigned alone for a few months. On the death of Egfrith the throne passed to Coenwulf, a descendant of Penda, father of Penda. In 821 Coenwulf was succeeded by his brother Ceolwulf, who was deprived of the throne in 823, being succeeded by Beornwulf. In 825 Beornwulf was defeated by Egberht, king of Wessex, and in the same year he was overthrown and slain by the East Angles. The supremacy now passed to Wessex.

In 827 Ludeca, the successor of Beornwulf, was slain in battle with five of his ears. Wigfrid, who succeeded him, was expelled two years later by Egberht, but regained the throne in the following year. In 838 he was defeated by his brother Aethelwulf, who reigned until 852. Under these later kings Mercia seems to have extended from the Humber to the Thames, including London, though East Anglia was independent, and that part of Essex which corresponds to the modern county of that name had been annexed to Wessex after 825. This date is that of either a reign of the Mercians over Wessex or of the Mercians over Wessex and Lessa. In 827 the Danes occupied London on their return from invading Wessex, after which a truce was again made. In 873 the Danes encamped at Torksey in Lincolnshire, and another truce ensued, they advanced in the following year to Repton, and Burgred was driven from the kingdom. He went to Rome, where he remained until his death. In England the power of Mercia was greatly diminished by the Danes, and definitely acknowledged their overlordship. In 877, after the second invasion of Wessex, the Danes seem to have taken the eastern part of Mercia into their own hands. How long Ceolwulf reigned over the western portion is unknown. About the year 884 the most important person in English Mercia was an earl, Æthelred, who accepted the suzerainty of Alfred, and in or before the year 887 married his daughter Æthelflaed. Æthelred and Æthelflaed appear to have had practically regal power, though they did not use the royal title. In 886 London, which had been recovered by Alfred from the Danes, was restored to Æthelred. During the invasion of 893-97 English Mercia was again repeatedly ravaged by the Danes; but in the last of these years, by the united efforts of Alfred and Æthelred, they were at length expelled. With this exception, Watling Street, the Ouse and the Lea, continued to be the boundary between Mercia and the Danish kingdom of East Anglia down to the death of Æthelred, between 910 and 912. The government was then carried on by Æthelhæl, who built a number of fortresses, and in conjunction with his brother, King Edward the Elder, succeeded in expelling the Danes from Derby and Leicester by the year 917-18. After her death in the latter year her daughter Ælfwyn was soon deprived of the government by Edward, and Mercia was definitely annexed to Wessex.

From this time onwards its existence as a separate kingdom was at an end, though during the last years of Eadwig’s reign the Mercians and NorthUMBrians set up Eadgar as king. In the last century of the Saxon period the ears of Mercia frequently occupied a semi-royal position. The most important of these were Ælhere under Eadgar’s Edward and Æthelred, Eadric his brother under the last-mentioned king, and Leofric, under the Danish kings.

**Mercie, Marius Jean Antonin (1845-1902).** French sculptor and painter, was born in Toulouse on the 30th of October 1845. He entered the Ecole des Beaux Arts, Paris, and studied under Falguière and Jouffroy, and in 1868 gained the Grand Prix
MERCIER, H.—MERCK

de Rome. His first great popular successes were the "David" and "Gloria Victis," which was shown and received the medal of honour of the Salon. The bronze was subsequently placed in the Square Montbazon, "The Genius of the Arts" (1877), a relief planted in the Institution of the Société des Hommes de Napoleon III; a similar work for the tomb of Michelet (1879) was set up at Belfort and in the garden of the Tulleries. "Le Souvenir" (1888), a marble statue for the tomb of Mme Charles Ferry, is one of his most beautiful works. "Regret," for the tomb of Cabanel, was produced in 1892, along with "William Tell," now at Lorraine. Mercier also designed the monuments to "Meissonier" (1895), erected in the Jardin de l'Infante in the Louvre, and "Faidherbe" (1860) at Lille, a statue of "Thiers" set up at St Germain-en-Laye, the monument to "Baudry" at Père-la-Chaise, and that of "Louis-Philippe and Queen Amélie" for their tomb at Dreux. His stone group of "Justice" is at the Hôtel de Ville, Paris. Numerous other statues, portrait busts, and medallions came from the sculptor's hand, which gained him a medal of honour at the Paris Exhibitions of 1878 and the grand prix at that of 1889. Among the paintings exhibited by the artist at the Salon, "Venus," to which was added "Le Jove" (1884), and "Michael-angelo studying Anatomy" (1889)—his most dramatic work in this medium. Mercier was appointed professor of drawing and sculpture at the École des Beaux Arts, and was elected a member of the Académie Française in 1891, after being awarded the biennial prize of the institute of $300 in 1887.

MERCIER, HONORÉ (1840-1904), Canadian lawyer and statesman, was the son of Jean Baptiste Mercier, farmer, and of Marie Kimener, his wife. He was born in the village of St Athanase d'Iberville on the 15th of October 1840. The family moved to Quebec and settled in the town of Mercier, Magog, and later removed to Iberville. Mercier entered the Jesuit College of St Mary, Montreal, at the age of fourteen, and throughout his life retained a warm friendship for the society. He married, firstly in 1866 Leopoldine Bolvin, and secondly in 1871 Virginie St Denis. On the completion of his course at St Mary's he studied law in the office of Laframboise and Papineau, in St Hyacinthe, and was admitted to the bar of the province in April 1865. At the age of twenty-two he became the editor of the Conservative Courrier de St Hyacinthe, and in this capacity so far as could be done in a political party that was then representative of the interests of Quebec, under the Act of Union (1840); but when Sicotte accepted a seat on the bench Mercier joined the Opposition, and contributed largely to the defeat of the Ministerial candidate. In 1864 he vigorously opposed the scheme of confederation, on the ground that it would prove fatal to the distinctive position held by the French Canadians. He resumed the editorship of the Courrier in 1866; but after a few months retired from journalism, and for the next five years devoted all his energy to his profession. At the commencement of the year 1871 the national party was organized in Quebec, and Mercier entered as a member of the party, a position which he retained until the formation of the provincial party. The convention of 1873 called together for the purpose of discussing the possibility of forming a party, and at this convention Mercier was elected as the member of the House of Commons for the county of Rouville, and proved a vigorous opponent of Sir John A. Macdonald on the question of separate schools for New Brunswick. He was a candidate at the general elections in 1874; but retired on the eve of the contest in favour of another candidate of his own party. Mercier entered the arena of provincial politics in May 1879 as solicitor-general in the Joly government, representing the county of St Hyacinthe; and on the defeat of the ministry in October he was appointed a member of the cabinet, and on the retirement of M. Joly from the leadership of the Liberal party in Quebec in 1883 Mercier was chosen as his successor. Towards the close of 1885 the French-Canadian mind was greatly agitated over the execution of Louis Riel, leader of the north-west rebellion, and in consequence of the attitude of Mercier on this question the Liberal minority in the Legislative Assembly, which had been reduced to fifteen, rapidly gained strength, until at the general elections held in October 1886 the province was carried in the Liberal interest. In January 1887 Mercier was sworn in as premier and attorney-general, and from this moment he exercised the sovereignty of the province. He succeeded in passing without opposition the Jesuit Estates Act, a measure to compensate the order for the loss of property confiscated by the Crown. This act came before the Federal House for disallowance, but was carried on division. When Mercier appealed to the electorate in 1890, his policy was endorsed, and he was able to give effect to many important measures. Early in 1891 he negotiated a loan in Europe for the province, and whilst on a visit to Rome he was created a count of the Roman Empire by Leo XIII., and three years previously had conferred upon him the rank of a commander of the order of St Gregory the Great. Of commanding presence, firm, decisive, courteous in manner, convincing in argument, and deeply attached to his native province, he had all the qualities of a popular leader. For a few years he was the idol of the people of Quebec, and French Canada loomed large in the public eye; but towards the end of 1891 serious charges were preferred against his ministry, on the ground that subsidies voted for railways had been diverted to political use, and he was dismissed by the lieutenant-governor. At the subsequent elections held in March 1892 he was returned for the county of Bonaventure, but was defeated. On the formation of a new government he was brought to trial, and declared not guilty; his health, however, gave way, and he never regained his former influence.

See Biographie, discours, conférences, etc., de l'Hon. Honoré Mercier, by J.-O. Poland (Montreal, 1893) (A. G. D.)

MERCIER, LOUIS SEBASTIEN (1740-1814), French dramatist and miscellaneous writer, was born in Paris on the 6th of June 1740. He began his literary career by writing heroic epistles, but early came to the conclusion that Boileau and Voltaire could not save the French language as long as the people continued to be educated by the priests. He therefore turned to prose. The most important of his miscellaneous works are L'An 2440 (1770); L'Essai sur l'Art Dramatique (1773); Neologie (1801); Le Tableau de Paris (1781-1788); Le nouveau Paris (1790); Histoire de France (1802) and Satire contre Racine et Boileau (1808). He decried French tragedy as a caricature of antique and foreign customs in bombastic verse, and advocated the comédie larmoyante as understood by Diderot. To the philosophers he was entirely hostile. He denied that modern science had made any real advance; he even carried this conservatism so far as to maintain that the sun revolved in a flat plain which revolved the sun. Mercier wrote some sixty dramas, among which may be mentioned Jean Henneury (1772); La Destruction de la Ligue (1782); Jennévél (1766); Le Juge (1774); Natalie (1773) and La Brouette du vinagrier (1775). In politics he was a Moderate, and as a member of the Convention he voted against the death penalty for Louis XVI. During the Terror he was imprisoned, but was released after the fall of Robespierre. He died in Paris on the 25th of April 1814.

See Léon Bechard, Sebastien Mercier, sa vie, son œuvre (Paris, 1903); R. Duunic in the Revue des deux mondes (15th July 1903).

MERCER, JOHANN HEINRICH (1747-1791), German author and critic, was born at Darmstadt on the 11th of April 1741, a few days after the death of his father, a chemist. He studied law at Giessen, and in 1767 was given an appointment in the paymaster's department at Darmstadt, and a year later himself became paymaster. For a number of years he exercised considerable influence upon the literary movement in Germany; he helped to found the Frankfurter gelehrte Anzeigen in 1772, and was one of the chief contributors to Nicolaí's Allgemeine Bibliothek. In 1782 he accompanied the Landgrave Karoline of Hesse-Darmstadt to St Petersburg, and on his return was a guest of the duke Charles Augustus of Weimar in the Wartburg. Unfortunate speculations brought him into pecuniary embarrassment in 1788, and although friends, notably Goethe, were ready to come to his assistance, his losses—combined with the death of five of his children—took a toll upon his mind that he committed
suicide on the 27th of June 1791. Merck distinguished himself mainly as a critic; his keen perception, critical perspicacity and refined taste made him a valuable guide to the young writers of the Sturm und Drang. He also wrote a number of small treatises, dealing mostly with literature and art, especially painting, and a few poems, stories, narratives and the like; but they have not much intrinsic importance. Merck's letters are particularly interesting and instructive, and throw much light upon the literary conditions of his time.

Merck's Ausgewählte Schriften zur schönen Literatur und Kunst were published by A. Stahr in 1840, with a biography. See Briefe an J. H. Merck von Goethe, Herder, Wieland and andern bedeutenden Zeitgenossen (1835), Briefe an und von J. H. Merck (1838) and Briefe an und von Goethe, Herder, Hölderlin and Merck (1847), all edited by K. Wagner. Cf. G. Zimmermann, J. H. Merck, seine Umgebung und seine Zeit (1871).

**MERCUR—MERCURY**

The estate of Mercour in Auvergne, France, gave its name to a line of powerful lords, which became extinct in the 14th century, and passed by inheritance to the dauphins of Auvergne, counts of Clermont. In 1446 it passed to the Bourbons by the marriage of Louis I, dauphin of Bourbon, count of Montpensier. It formed part of the confiscated estates of the Constable of Bourbon, and was given by Francis I and Louise of Savoy to Antoine, duke of Lorraine, and his wife, Renée de Bourbon. Nicolas of Lorraine, son of Duke Antoine, was created duke of Mercour and a peer of France in 1569. His son Philippe Emmanuel (see below) left a daughter, who married the duc de Vendôme in 1609.

**MERCOUR, PHILIPPE EMMANUEL DE LORRAINE, Duc de (1558–1602), French soldier, was born on the 9th of September 1558, and married Marie de Luxemburg, duchesse de Penthièvre.** In 1582 he was made governor of Brittany by Henry III, who had married his sister. Mauceur put himself at the head of the League in Brittany, and had himself proclaimed protector of the Roman Catholic Church in the province in 1588. Invoking the hereditary rights of his wife, who was a descendant of the dukes of Brittany, he endeavoured to make himself independent in that province, and organized a government at Nantes, calling his son "prince and duke of Brittany." With the aid of the Spaniards he defeated the duc de Montpensier, whom Henry IV. had sent against him, at Craon in 1592, but the royal troops, reinforced by English contingents, soon recovered the advantage. The king marched against Mercour in person, and received his submission at Angers on the 20th of March 1598. Mercour subsequently went to Hungary, where he entered the service of the emperor Rudolph II, and fought against the Turks, taking Stuhlweissenburg (Székes-Fehérvár) in 1599. Mercour died on the 19th of February 1602.

**MERCURY** (Mercurius), in Roman mythology, the god of merchandise (merx) and merchants; later identified with the Greek Hermes. His nature is more intelligible and simple than that of any other Roman deity. In the native Italian states no trade existed till the influence of the Greek colonies on the coast introduced Greek customs and terminology. It was no doubt under the rule of the Tarquins that merchants began to ply their trade. Doubtless the merchants practised their religious ceremonies from the first, but their god Mercurius was not officially recognized by the state till the year 495 B.C. Rome frequently suffered from scarcity of grain during the unsettled times that followed the expulsion of the Tarquins. Various religious innovations were made to propitiate the gods; in 496 the Greek worship of Demeter, Dionysus and Persephone was established in the city, and in 493 the Greek god Hermes was introduced into Rome under the Roman name of Mercurio (Livy ii. 21, 27), as protector of the grain trade, especially with Sicily. Preller thinks that at the same time the trade in grain was regulated by law and a regular college or guild of merchants instituted. This college was under the protection of the god; its annual festival was on the 15th (the ides) of May, on which day the temple of the god had been dedicated at the southern end of the Circus Maximus, near the Aventine; and the members were called mercuriales as well as mercatores. Mommssen, however, considers the mercuriales to be a purely local guild—the pagani of the Circus valley. The 15th of May was chosen as the feast of Mercury, obviously because Maia was the mother of Hermes, that is of Mercury; and she was worshipped along with her son by the mercuriales on this day. According to Peller, this religious foundation had a political object; it established on a legitimate and sure basis the trade between Rome and the Greek colonies of the coast, whereas formerly this trade had been exposed to the capricious interference of government officials. Like all borrowed religions in Rome, it must have brought with it new forms and a new terminology of its Greek original (Festus p. 239). Mercury became the god, not only of the mercatores and of the grain trade, but of buying and selling in general; and it appears that, at least in the streets where shops were common, little chapels and images of the god were erected. There was a spring dedicated to Mercury between his temple and the Porta Capena; every shopman drew water from this spring on the 15th of May, and sprinkled it with a laurel twig over his head and over his goods, at the same time entreating Mercury to remove from his head and his goods the guilt of all his deceits (Ovid, Fasti, v. 673 seq.). This image of mercurialis was popularly used as equivalent to "cheat."

Roman statuettes of bronze, in which Mercury is represented, like the Greek Hermes, standing holding the caduceus or staff in the one hand and a purse in the other (an element very rare in purely Hellenic representations), are exceedingly common.

**MERCURY, in astronomy, the smallest major planet and the nearest to the sun; its symbol is ♄. Its proximity to the sun makes the telescopic study of its physical constitution extremely difficult. The result is that less is known on this subject than on that of any other planet.** Even the time of rotation on its axis is uncertain. J. H. Schröter inferred a period of rotation of 24 h. 5 m. 30 s., which was in seeming agreement with the observations of K. L. Harding. This period was generally accepted, though Herschel had been unable to see any changes indicating rotation. In 1838 G. Schiaparelli began a careful study of the face of the planet with a refractor of 8 in. aperture, subsequently replaced by one of 18 in. His unexpected conclusion was that the rotation of Mercury resembles that of the moon, in having its period equal to that of its orbital revolution. As the moon always presents the same face to the earth, so Mercury must, in this case, always present very nearly the same face to the sun. Schiaparelli also announced that the axis of rotation of the planet is nearly perpendicular to the plane of its orbit. The rotation being uniform, while the orbital motion, owing to the great eccentricity of the orbit, is affected by a very large inequality, it would follow that there is a libration in longitude of nearly 24° on each side of the mean position. Percival Lowell in 1897 took up the question anew by combining a long series of measured diameters of the planet with drawings of its apparent surface. The seeming constancy of the surface appearance was considered to confirm the view of Schiaparelli as to the slow rotation of the planet. But there is wide room for doubt on the question.

The period of orbital revolution of Mercury is nearly 88 days, or somewhat less than three months. Consequently, the period of synodic revolution is less than four months, during which the entire round of phases is completed. When near greatest elongation Mercury shines as a star of the first magnitude, or brighter; but in the latitudes of central and northern Europe it is so near the horizon soon after sunset as to be generally obscured by vapours or clouds.

The eccentricity of the orbit, 0-20, is far greater than that of any major planet, and nearly the average of that of the minor planets. Consequently, its distance and its greatest elongation from the sun vary widely with its position in its orbit at the time.

The mass of Mercury can be determined only from its action upon Venus; this is so small that the result is doubtful. Leverrier adopted in his tables 1: 3,000,000 as the ratio of the mass of Mercury to that of the sun. S. Newcomb, from the action upon Venus, reduced this to one-half its amount, or 1: 6,000,000.
G. W. Hill, basing his conclusions on the probable density of the planet, estimated the mass to be less than $10,000,000$. The adoption of a mass even as large as that of Newcomb implies a greater density than that of the earth, but it is not possible to estimate the probability that such is the case.

The most interesting phenomenon connected with Mercury is that of its occasional transit over the disk of the sun at inferior conjunction. These occur only when the planet is near one of its nodes at the time. The earth, in its orbital revolution, passes through the line of the nodes of Mercury about the 8th of May and the 10th of November of each year. It is only near one of these times that a transit can occur. The periodic times of Mercury and the earth are such that the transits are generally repeated in a cycle of 46 years, during which 8 transits occur in May and 6 in November. The following table shows the Greenwich mean time of the middle of all the transits from 1677, the date of the first one accurately observed, until the end of the present century.

A perplexing problem is offered by the secular motion of the perihelion of Mercury. In 1845 Leverrier found that this motion, as derived from observation of the transits, was greater by $35^\circ$ per century than it should be from the gravitation of all the other planets. This conclusion has been fully confirmed by subsequent investigations, a recent discussion showing the excess of motion to be $45^\circ$ per century. It follows from this either that Mercury is acted upon by some unknown masses of matter, or that the intensity of gravitation does not precisely follow Newton’s law. The most natural explanation was proposed by Leverrier, who attributed the excess of motion to the action of a group of intra-Mercurial planets. At first this conclusion seemed to be confirmed by the fact that occasional observations of the transit of a dark object over the sun had been observed. But no such observation was ever made by an experienced astronomer, and the frequent photographs of the sun, which have been taken at the Greenwich observatory and elsewhere since 1870, have never shown the existence of any such body. We may therefore regard it as certain that, if a group of intra-Mercurial planets exists, its members are too small to be seen when projected on the sun’s disk. During the eclipses of 1900 and 1905 the astronomers of the Harvard and Lick Observatories photographed the sky in the neighbourhood of the sun so fully that the stars down to the 7th or 8th magnitude were imprinted on the plates. Careful examination failed to show the existence of any unknown body. It follows that if the group exists the members must be so small as to be entirely invisible. But in this case they must be so numerous that they should be visible as a diffused illumination on the sky after sunset. Such an illumination is shown by the zodiacal light. But such a group of bodies, if situated in the plane of the ecliptic, would produce a motion of the node of Mercury equal to that of its perihelion, while the observed motion of the node of Mercury is somewhat less than that computed from the gravitation of the known planets. The same is true of the node of Venus, which might also be affected by the same attraction. To produce the observed result, the inclination of the ring would have to be greater than that of the orbit of either Mercury or Venus. In 1845 Newcomb showed that the observed motions, both of the perihelion of Mercury and of the nodes of Mercury and Venus, could be approximately represented by the attraction of a ring of inter-mercurial bodies having a mean inclination of $9^\circ$ and the mean node in $48^\circ$ longitude. He also showed that if the ring was placed between the orbits of Mercury and Venus, the inclination would be $7.5^\circ$ and the longitude of the node $35^\circ$. The fact that the zodiacal light appears to be near the ecliptic, and the belief that, if it were composed of a lens of discrete particles, their nodes would tend to scatter themselves equally around the invariable plane of the solar system, led him to drop these explanations as unsatisfactory, and to prefer provisionally the hypothesis that the sun’s gravitation is not exactly as the inverse square. (See Gravitation.)

In 1896 H. H. Seeliger made a more thorough investigation than his predecessor had done of the attraction of the matter producing the zodiacal light, assuming it to be formed of a series of ellipsoids. He showed that the motions of the nodes and perihelion could be satisfactorily represented in this way. The following are the three principal elements of the hypothetical orbits as found by the two investigators:

The demonstration by E. W. Brown that the motion of the moon’s perigee is exactly accordant with the Newtonian law of gravitation, seems to preclude the possibility of any deviation from that law, and renders the hypothesis of Seeliger the most probable one in the present state of knowledge. But the question is still an open one whether the zodiacal light has an inclination of the ecliptic as great as that computed by Seeliger. This is a difficult one because the action on Mercury is produced by the inner portions of the matter producing the zodiacal light. These are so near the sun that they cannot be observed unless possibly during a total eclipse.

Mercury (symbol Hg, atomic weight = 200), in chemistry, a metallic element which is easily distinguished from all others by its being liquid at even the lowest temperatures naturally occurring in moderate climates. To this exceptional property it owes the synonyms of quicksilver in English (with the Germans Quecksilber is the only recognized name) and of hydrargyrum (from ὑδραργύρος, water, and ἄργυρος, silver) in Graeco-Latin. This metal does not appear to have been known to the ancient Jews, nor is it mentioned by the earlier Greek writers. Theophrastus (c. 350 B.C.) mentions it as prepared from copper by treatment with copper and vinegar; Dioscorides obtained it from the same mineral with the aid of iron, employing at the same time a primitive distillation apparatus. With the alchemists it was a substance of great consequence. Its appearance commended it as a substance for investigation; many of its compounds, especially corrosive sublimate and calomel, were studied, and improved methods for extracting and purifying the metal were devised. Being ignorant of its susceptibility of freezing into a compact solid, they did not recognize it as a true metal, and yet, on the authority of Geber, they held that mercury (meaning the predominating element in this metal) enters into the composition of all metals, and is the very cause of their metallicty (see Element). When, about the beginning of the 16th century, chemistry and scientific medicine came to merge into one, this same mysterious element of “mercury” played a great part in the theories of pathology; and the metal,
in the free as in certain combined states, came to be looked upon as a powerful medicinal agent.

Metallurgy.—Chemically speaking, the extraction of mercury from cinnabar is a simple matter. Metallic mercury is easily volatilized, and separated from the gangue, at temperatures far below redness, and cinnabar at a red heat is readily reduced to the metallic state by the action of carbon monoxide. The mercury thus produced is not pure, but may be once more distilled, in the first case as iron sulphide, in the second as calcium sulphide and sulphate, in the third as sulphur dioxide. A close iron retort would at first suggest itself as the proper kind of retort, but it has been found that carbon is too slow-acting a reducing agent, and that one, acted upon in a few small establishments—for instance, in that of Zweibrücken in the Palatinate, where lime was used as a decomposing agent; but the method has not been perfected in this way. In all the cases, the cinnabar is affected by the direct exposure of the ore to the oxidizing flame of a furnace, and the mercury vapour, which gets diffused through an immense mass of combustion gases, is recovered in more or less imperfect condensers.

Mercury is transported in steel bottles closed by a screw stopper; the Almaden and Idrian bottles contain 76 lb; and until the 1st of June 1904, the Californian bottles contained 76 1/2 lb of mercury; they now hold 75 lb. From the smaller works the metal is sometimes sent out in sheepskin bags holding 55 lbs of mercury.

Production.—At one time the world's supply of mercury was almost entirely derived from the Almaden and Idrian mines; but now the greatest proportion is produced in California and Texas, where cinnabar was used by the Indians as a pigment, and first turned to metallurgical purpose in 1845 by Castellero.

In the United States mercury has also been found in Utah, Nevada, Oregon and Arizona. In the 16th century the Almaden and Idrian mines were practically the only producers of this metal; statistics of Almaden dating from 1564 and of Idria since 1525 are given in B. Neumann, Die Metalle (1904). Spain produced 1150 metric tons in 1870, and in 1889 its maximum of 1975 tons; since then it has had the whole, been decreased. The Almaden output steadily increased to about 550-600 tons at which it appears to remain. In 1887 Russia produced 64 tons, and has steadily improved. The United States output was over 1000 tons, in 1871, and declined to 800-900 in the period 1889-1892; it has since increased and surpassed the supply from Spain. The following table gives the production in various countries for selected years:

1 Estimated.
furnaces and condensers and to avoid the salivation of the workman. (6) The condenser should be easily and quickly cleaned during the operation of the furnace. (7) Both furnaces and condensers should have provision for preventing the escape of escaping gases, and also for catching and condensing the condensate or smoke. (8) There is a great need of some substance for the construction of quicksilver condensers which shall be strong enough to be made thin, be a good conductor of heat, and resistant to heat and cold, and which shall not be attacked by the action of mercury, or be easily dissolved in it, and also resist the action of mercury and warm dilute sulphuric acid, and be not too expensive.

Column.-When columns are formed by heating glass, the latter consists of mercury lost as vapour and as nit, and its minimum amount is determined not by the richness of the ore but by the volume of escaping gases, their velocity and temperature. The percentage of loss will be higher with a poor than a rich ore. On a 1% ore they will run from 5 to 10%. In badly arranged plants, under bad management they may easily be doubled or even trebled. The buttet of gas formed by furnace costs with condensers in California about $30,000, and reduces 39 to 44 tons of nit (from 2 in. to dust) in 24 hours at a cost of from $1 to $62 per ton.

Purification.—Commercial mercury, as a rule, only needs to be forced through chamois leather or allowed to run through a very fine hole or tube, which is kept alternately moistened with nitric acid and nitric acid, or of potassium bichromate and sulphuric acid; the metal will then be entirely dissolved and filtered through a paper filter. The only really effective method is distillation in a vacuum out of a glass apparatus. Many forms of apparatus have been devised to effect this. Recent researches have shown, however, that the metal so obtained is not chemically pure, there being found in the distillate traces of other metals. Absolutely pure mercury does not at all adhere to any surface which does not consist of a metal soluble in mercury. Hence the least quantity of it, when placed on a sheet of paper, forms a neatly rounded-off globule, which retains its form being rolled about, and, when subdivided, breaks up into a number of equally perfect globules, which tend to coalesce when heated, but, on cooling, exist in the original form on a minute test of lead or tin causes it to "draw tails." A very impure metal may adhere even to glass, and in a glass vessel, instead of the normal convex, form an irregular flat meniscus.

Properties.—Pure mercury is a freely flowing liquid, which in its original, or 86° state, is used by chemists and metallurgists in its pure state, for it is comparatively cheap, and perfect metallic lustre; in very thin layers it transmits a bluish-violet light. It freezes at about −38.8° C. (Mallet gives −38.88°; Hutchinson, −39.44°) with contraction, and the formation of a white, very ductile and malleable mass, easily cut with a knife, and exhibiting crystals belonging to the cubic system. When heated the metal expands very uniformly, and vaporizes at about 360°; the volatility is greatly increased by the presence of impurities; its high expansion and the wide range of temperature over which it is fluid render it especially valuable as a thermometric fluid (see Thermometry). The volume is colored by the impregnation that the crystals are monatomic. Its specific gravity at 0° is 13.5959, i.e., it is about half as heavy again as copper for volume, a quarter as heavy again as lead, and nearly twice as heavy as zinc; this property is turned to account in the construction of barometers and air-pumps. Its specific heat is about 0.1933 (see Calorimetry); its electrical conductivity is involved in the definition of the ohm (see Conduction, Electric); and its thermal conductivity is about two thirds that of silver.

Pure mercury remains unchanged in dry air, oxygen, nitrogen, carbon dioxide, ammonia, and some other gases at ordinary temperatures; hence its application for collecting and measuring gases. In damp air it slowly becomes coated with a film of mercuric oxide; and when heated for some time in air or oxygen it becomes transformed into the red mercuric oxide, which decomposes into mercury and oxygen when heated to a higher temperature; this reaction is of great historical importance, since it led to the discovery of oxygen at the hands of Priestley and Scheele. The halogen elements and sulphur combine directly with the metal. Mercury is unaffected by dilute sulphuric acid; the strong acid, however, dissolves it on heating with the formation of sulphur dioxide and mercuric or mercuric sulphate according as mercury is in excess or not. Hydrochloric acid has no action. Dilute nitric acid readily attacks it, mercuric nitrate being formed in the cold with excess of mercury, mercuric nitrate with excess of acid, or with strong nitric acid. The metal dissolves in solutions containing chloride or bromide of sodium or potassium, or tetra-methylamylammonium chloride or bromide. Mercury readily dissolves many metals to form a class of compounds termed amalgams, which have considerable applications in the arts.

Compounds of Mercury.

Mercury forms two well-defined series of salts—the mercuric salts derived from the oxide HgO, and the mercuric salts from the oxide HgO; the existence of these salts can hardly be inseparably connected with a variable valency, i.e., that mercury is monovalent in mercuric, and divalent in mercuric compounds, for, according to Barrow (in his chemical cabinet (g.v.)) the formula HgCl₂, Mercurous Oxide, HgO, is a modifying compound, when caustic potash acts on calomel; it is decomposed by light or on trituration into mercury and mercuric oxide Mercuric oxide, Hg₃O, is a two to two compound of two elements. A mercuric salt (also known as "red precipitate," or as mercurious precipitate, mercuric per se) by heating the metal in air, or by calcining the nitrate, and as an yellow-orange powder by precipitating a solution of a mercuric double salt with potassium iodide. Of the iodides, the potassium is the most reactive and is transformed into the red when heated to 400°. If the red oxide be heated it becomes black and probably transformed into the fume, and on further heating to 600° it decomposes into mercury and oxygen, forming a yellow oxide of the nitrate melting in water, to which it imparts an alkaline reaction and strongly metallic taste. A peroxide is obtained as a brown solid from mercury and peroxide, or acid, or sublimation. Mercury and mercuric chlorides, known respectively as calomel (g.v.) and corrosive sublimate (g.v.), are two of the most important salts of mercury. Mercurous bromide, HgBr₂, is a yellowish-white powder, insoluble in water, soluble in nitric acid, HgBr₂ forms white crystals, sparingly soluble in cold water, readily in hot, and prepared by the direct union of its components. Mercurous iodide, HgI₂, is a yellowish-green powder obtained by heating its component to about 250°, or by triturating them with a little alcohol; it is also obtained by precipitating a solution of mercuric nitrate with potassium iodide. It is blackened by exposure to light. Mercuric iodide dissolves in water to form a solution of potassium iodide, K₂HgI₄, which may be obtained in lemon-yellow crystals. A strongly alkaline solution of this salt is known as Nessler's reagent, and is specially used for determining traces of ammonia (see below). Mercuric iodide dissolves in potassium hydroxide to form similar compounds; these solutions are characterized by their exceptionally high specific gravity, and hence are employed in density determinations (see Densitometry). It also forms many other double salts. Oxidation with strong nitric acid gives the iodate, HgO(O₃). An iodide, HgI₄, intermediate between mercurous and mercuric iodides, is obtained as a yellow insoluble powder by precipitating mercuric iodide with a dilute solution of iodine in potassium iodide. Mercurofluoride, HgF₂, and mercuric fluoride, HgF₃, are unstable substances obtained from the corresponding oxide and hydroluoric acid.

Mercuric Nitrate, Hg(NO₃)₂, H₂O, is obtained as a white crystalline salt soluble in water. It is decomposed by dilute nitric acid; if the metal be in excess a basic salt Hg(NO₃)₂ is obtained. 3H₂O is obtained. Several other basic salts are known. By adding ammonium salts, a mercuric nitrate a bladder precipitate of mercuric sulphotungstate composition, known in pharmacy as mercurius solubilis, is obtained.

Mercuric Nitrate.—By dissolving mercuric oxide in strong nitric acid an oxide of mercury is obtained which undergoes decomposition at 10°, which gives on the addition of strong nitric acid a white precipitate of Hg(NO₃)₂, H₂O. Water decomposes it to give basic salts of variable composition. By dissolving the oxide in dilute nitric acid, a mercuric salt Hg(NO₃)₂, H₂O, H₂O, crystallizing in needles, is obtained.

Mercurous Sulphide, HgS, is an unstable black powder obtained by acting with sulphuretted hydrogen, diluted with carbon dioxide, into metallic mercury and mercury at 0°. Mercuric sulphide, HgS, is one of the most important
mercury compounds; it is the principal ore, occurring in nature as the mineral cinnabar (q.v.), and is extensively used as a pigment, vermilion (q.v.). It is obtained as a white powder by distilling a mercuric nitrate solution. The compound thus formed is known in pharmacy as *Aethiops minerals*, and also by precipitating a mercuric salt with sulphurised hydrogen. It is only slightly active, and will not give solutions through any part of the solution. It gives a yellow compound, 2HgS, HgCl₂; and it dissolves in potassium sulphide solutions to form double salts of variable composition.

*Mercurius Sulfate*, HgSO₄, is a white, sparingly soluble, crystal-like substance obtained by adding sulphuric acid to a solution of mercurous nitrate. *Mercuric sulphate*, Hg₂SO₄, is a white, soluble salt, which, being precipitated from solution by ammonia acid; on digestion with water, it decomposes into a basic salt, Hg₂SO₄, 2H₂O known as *turbid or turpeth mineral*, and into an acid salt, HgSO₄, 3H₂O. Hg₂S₂O₃ is obtained as brilliant red, hexagonal crystals by heating mercury with phosphorus iodide to 300° and removing the mercuric iodide simultaneously formed by means of potassium iodide solution. *Mercurius, phosphate, Hg₃(PO₄)_₂, and mercuric phosphate, Hg₃(PO₄)_₂*, are obtained as white precipitates by adding sulphuric acid to solutions of mercurous and mercuric nitrates respectively.

**Compounds.**—By the action of ammonia and ammonium salts mercury compounds yield a number of substances, many of which have long been used in medicine. By the action of dry ammonia on calomel mercuric-ammonium chloride, NH₄HgCl, is formed. Upon aqueous ammonia or calomel, a yellow calomel or mercurous-ammonium chloride, NH₄HgCl₂, is formed. By adding ammonia to a solution of mercuric chloride, mercuriammonium chloride, known in pharmacy as *mercurium nigra* and precipitate, NH₄HgCl, is formed. The precipitate can be obtained as mercuric chloride, Hg(NH₂Cl), and obtained by adding a solution of mercuric chloride to hot solutions of ammonium chloride and ammonia so long as the solution of mercuric chloride prevails, the white precipitate redissolves; the substance separates out on cooling. By precipitating a strongly alkaline solution of mercuric iodide in potassium iodide (Nessler's solution) there is obtained a yellow precipitate of NH₄HgI₂; this precipitate is the most delicate test for ammonia, a yellow coloration being given by minute traces. By passing dry ammonia over precipitated mercuric oxide at 130°, a nitride NH₄Hg is obtained. The oxidised ammonia gives rise to the stable and basic mercuric hydroxide, NH₄HgOH. The constitution of these compounds has been especially studied by K. A. Hofmann and E. C. Marbury (Zet. Anorg. Chem., 23, p. 120); these chemists formulate "insoluble precipitate" as Hg(NH₂Cl), "soluble precipitate" as Hg(NH₂CO₃).

"Millon's base" as (HO₃H₂)₂HgOH, thus postulating three distinct types of compounds, (1) amidochlorides; (2) amines; (3) substituted ammonium derivatives.

**Analysis.**—Mercury compounds, when heated in a closed tube with sodium carbonate, yield a grey to black sublimate of metallic mercury, which readily unites to form visible globules. The metal is precipitated from solutions by calomel, a coating being formed on the copper, which becomes silvery on rubbing, and disappears when the quicksilvered copper is heated in a sublimation tube.

Sulphur and metallic salts with hydrochloric acid give a white precipitate of calomel, which becomes jet-black on treatment with ammonia. Stannous, in its twofold capacity as a chloride and a reducing agent, precipitates both mercurous and mercuric materials, at first as calomel, and on addition of an excess of reagent, the precipitate becomes grey through conversion into finely-divided quicksilver. Sulphuretted hydrogen, when added very gradually to an acid mercuric solution, gives at first an almost white precipitate, which, on addition of more and more reagent, assumes successively a yellow, orange and at last jet-black colour. The black precipitate is HgS, which is identified by its great heaviness, and by being insoluble in boiling nitric and in boiling hydrochloric acid. A mixture of the two (aqua regia) dissolves it as chloride.

"Mercurochrome" mercury is quantitatively estimated by precipitating as calomel and weighing the precipitate on a tared filter at 100°. The precipitate is separated and washed with boiling water and lime, the metal being collected and weighed, or by precipitating the solution with an excess of stannous chloride. More convenient is the method of precipitating its sulphide by an excess of sulphuretted hydrogen, and weighing the precipitate on a tared filter; or by means of a Gooch crucible.

**Pharmacology and Therapeutics.**

The use of mercury as a therapeutic agent is of comparatively recent date. To the Greeks and Romans its value was unknown, and the Arabian physicians only used it for skin affections. It was not until the middle of the 16th century that the special properties of mercury were fully appreciated, but since that time the metal has continued to hold a high though fluctuating value as a medicine. At first the metal in a finely divided state or in vapour was used; but very soon its various compounds were found to be endowed with powers even greater than those of the metal itself, and with the discovery of new compounds the number of mercurial medicines has largely increased.

The British Pharmacopoeia contains some twenty-five mercurial preparations, including some of calomel (q.v.). Only the useful preparations will be noticed here. Among the first to be employed was in Hydrargyrum cum Creta, or "grey powder," which consists of one part of mercury to two of prepared chalk. The power of this valuable and active medicinal body is not strong, and it is usually used for adults. There are also five preparations of free mercury for external use. Of these the most useful is the Unguentum Hydrargyri, or "blue ointment," which contains one part of subjugated mercuric chloride in the red and the yellow forms of mercuric oxide. The peroxide of mercury or corrosive sublimate is therapeutically the most important salt of mercury. The dose is 1 to 2 gr. It is incinerated with alkalis, alkaline carbonates, potassium iodide, albumen, and many other substances, and should therefore be prescribed alone. It is decomposed by impure water, and distilled water is therefore preferred. The Peroxide, which, in form it is usually prescribed. This contains half a grain of the peroxide to the fluid ounce and its dose is 30 to 60 minims. The peroxide is also compounded with lime-water to contain the Lotio Hydrargyri Flavi, or *yellow ointment*. It consists of half a grain of the salt to the fluid ounce. Mercure iodide is an equally potent salt and has come into wide use of late years. It has the same dose as the above, and is supposed to be somewhat stronger. The Ointment of Hydrargyri Iodidi, or Donovan's solution, which contains 1% of arsenious iodide and 1% of mercuric iodide, the dose being 5 to 20 minims. An ointment widely used is prepared from the mercuric compound of the mercurous iodide. Hydrargyrum ammonium is a strong antipruritic and it is known as "white precipitate ointment."

In discussing the pharmacology of mercury and its compounds, it is of the first importance to observe that metallic mercury is inert as such, and that the same may practically be said of mercuric salts generally. Both mercury itself and mercuric salts tend to disappear in the body of the patient in whom they are given; this is due. When metallic mercury is triturated or exposed to air it is partly oxidized, the first stage of its transformation to an active condition being thus reached.

Metallic mercury can be absorbed by the skin, passing in minute globules through the ducts of the sweat-glands. The mercury contained in "blue ointment" is certainly thus absorbed, actually circulating in the blood in a very different form, as described below. There is no local action on the skin. The mercuric salts, and especially the chloride and iodide, are probably the most powerful of all known antiseptics. One part of the perchloride in 500,000 will prevent putrefaction in the presence of briefer bacilli. They are extensively employed in surgery—kills all known bacteria. The action is apparently specific and not due to the fact that per- chloride of mercury precipitates albumen, including the albuminous liquorum, bacteria, etc., for it will still act as an antiseptic, though it does not coagulate albumen. These salts cannot be employed for sterilizing metallic instruments, which they tarnish. As these drugs are essentially poisons they must be used with the greatest care in surgical practice, and as they are particularly deleterious to the secretory structure of the kidney they must not be employed as antiseptics in diseases where renal inflammation is already present or probable. They are therefore contra-indicated for application to the throat in scarlet-fever or to the uterus in eclampsia. The stronger mercurial ointments kill cutaneous parasites and also possess some degree of anti-pruritic action, especially when the case of Leprosy is one of sores or abscesses. As the weight of mercury is increased, it gives rise to a more extensive reaction, the occurrence of chronic mercurial poisoning in certain trades. Single doses of mercury or its compounds have no action upon the mouth, the characteristic salivation being produced only after many doses. Their typical action on the bowels is purgative, the effect varying with the state of the mercury. So relatively inert is metallic mercury that a pound of it has been given without ill effects in cases of intestinal obstruction. Many obsolete chemical applications, the mere weight of the metal. Half a grain of the perchloride, on the other hand, is a highly toxic dose. The action of mercurials on the bowels is mostly exerted on the duodenum and jejunum, though the lower part of the intestine is also somewhat involved. This fact explains why the mercury usually needs a saline aperient to complete its action, as in the blue pill and black draught of former days. Mercurials do not act on the stomach, in themselves, but when once the same secretion, the action being mainly exerted on the muscular wall of the bowel. The bile is rapidly removed from the duodenum, before any re-absorption can occur, and the bacterial action which
decomposes the bile-pigment is arrested by the antiseptic power of the
drug, so that the excreta are of a very dark colour. The classical
experiments of William Rutherford (1839-1899), of Edinburgh,
showed that calomel does not increase the amount of bile formed
by the liver, but only changes its composition. The increased with
the liver to a slight degree. The value of calomel in hepatic torpor is
as an excretory, not a secretory, cholagogue, the gall-bladder being
stimulated to expel its stagnant contents. In large doses mercurials
sometimes produce the symptoms of albuminuric disease, as
mercuric chloride administered by the mouth, in whatever form, is
excreted as mercuric sulphide. Prior to this decomposition the
mercury exerts a toxic effect on the liver, the kidneys, and
alimentary tract.

When perchloride of mercury is injected subcutaneously the
sodium chloride in the blood similarly prevents the precipitation
of the albuminate of mercury, and it is therefore desirable to add a
little sodium chloride to the injection of mercuric chloride in
clinical cases. Some observers assert that mercury is a haematinic, increasing,
like iron, the amount of haemoglobin in the blood. Whilst this is
doubtful it is certain that large doses, when continued, produce
marked anaemia. The excretion of the drug is accomplished by all
the secreting glands, including the breasts, if these are functioning.
All the secretions of the body, except that of the peptic glands of
the stomach, are stimulated, but the excretion in the mercury is slow,
and it is typically one of the drugs that are cumulative, like arsenic
and digitals.

Mercury is largely used in affections of the alimentary canal, and
has a remarkable value in the treatment of many cases of cancer
disease and arterial degeneration. But its value in syphilis (see
VENEREAL DISEASES) far outweighs all its other uses.

Testotoxicology.—Acute poisoning by mercurials usually occurs in the case
of general officers. The disease consists of gastro-intestinal inflammation,
with vomiting, frequent “rice-water” stools and extreme collapse.
The treatment, except when the case is seen at an early stage, is
wholly physiological, and赖is the antidote, forming an insoluble compound
with the perchloride.

Chronic poisoning (hynhydrism or mercurialism) is of great
importance, since any indication of its symptoms must be closely
watched for in patients who are under mercurial treatment. Usually
the first symptom is slight tenderness of the teeth whilst eating, and
some factor of the breath. These symptoms become more marked
and the gums become a seat of severe inflammation, being spongy,
vacuolar and prone to bleed. The salivary glands are swollen
and tender, and the saliva pours from the mouth, and may amount to
plints in the course of a day. The teeth become quite loose and may fall
out on being agitated, and the tongue is thick, fungous, and
ulcerate, the jaw-bone necroses, haemorrhages occur in various
parts of the body, and the patient dies of anemia, septic inflammation
or exhaustion. The treatment consists, besides stopping the intake of poison and relieving the symptoms, in the administration of potassium iodide in small, often repeated doses.

BIBLIOGRAPHY.—For the history of mercury see B. Neumann,
Die Metalle (1900); A. Rosing; Geschichte der Metalle (1901). The general
history in detail is given in D. O. Osgood’s The father; D. L. Moissan,
anorganisch Chemie, and H. Moisson, Traité de chimie minérale.
For the metallurgy reference may be made to Carl Schnabel, Hand-
book (1888); T. G. Smith, Manual of Chemistry, 1866.

MERCY (or MERCI), FRANZ, FREIHERR VON, LORD OF MANDRY
and COLENBURG (d. 1645), German general in the Thirty Years’
War, who came of a noble family of Lorraine, was born at
Longwy between 1590 and 1598. From 1666 to 1630 he
was engaged in the imperial service. By the latter year he had
attained high military rank, and after distinguishing himself at
the first battle of Breitenfeld (1631) he commanded a regiment
of foot on the Rhine and defended Rheinfelden against the
Swedes with the utmost bravery, surrendering only after enduring
a five-months’ siege. He now became general officer of
cavalry (General-Feldwachtmeister), and in 1635, 1636 and 1637
took part in further campaigns on the Rhine and Doubs.
In September 1638 he was made master-general of ordinance
in the army of Bavaria, then the second largest army in Germany.
In the next campaign he was practically commander-in-chief of
the Bavarians, and at times also of an allied army of Imperialists
and Bavarians. He was now considered one of the foremost
soldiers in Europe, and was made general field marshal in 1643,
when he won his great victory over the French marshal Rantzenau
at Tuttlingen (Nov. 24-25), capturing the marshal and seven
other generals. In 1644 he was appointed by the Emperor, who had
under the duke of Engenh (afterwards the great Conde) and the vicomte de Turenne.
He fought, and in the end
lost, the desperate battle of Freiburg, but revenged himself next
year by inflicting upon Turenne the defeat of Mergentheim
(Marienthal). Later in 1645, fighting once more against Engenh
and Turenne, Mercy was killed at the battle of Nördlingen (or
Allerheim) at the crisis of the engagement, which, even without
Mercy’s guiding hand, was almost a drawn battle. He died on the
3rd of August 1645. On the spot where he fell, Engenh
erected a memorial with the inscription Sla vistor, heroem calcas.

His grandnephew CLAUDE-LEOPOLD VILLETS, COUNT MERCY DE
(1666-1734), Imperial field marshal, son of his brother
Kasper, who fell at Freiburg, was born in Lorraine, and entered
the Austrian army as a volunteer in 1682. He won his commission
at the great battle of Vienna in the following year; and
during seven years of campaigning in Hungary rose to the rank
of Rittmeister. A wound sustained at this time permanently
injured his sight. For five years more, up to 1697, he was
employed in the Italian campaigns, then he was called back to
Hapsburg service. The Prince of Hohenlohe, who had won on the field of Zenta two
greats of promotion. He displayed great daring in the French
campaigns of the Spanish Succession War in Italy, twice fell into
the hands of the enemy in fights at close quarters and for his conduct at the surprise of Cremona (Jan. 31, 1702)
renounced the emperor’s thanks and the proprietary colonelcy of
a newly raised cuirassier regiment. With this he took part in
the Rhine campaign of 1703, and the battle of Friedlingen, and
his success as an intrepid leader of raids and forays became well
known to friend and foe. He was on that account selected early
in 1704 to carry the standards of Bavaria in the north German campaigns. He was
soon afterwards promoted General-Feldwachtmeister, and in 1705
rank he was engaged in the battle of the Schellenberg (July 2, 1704).
In the rest of the war he was often distinguished by his fiery courage. He rose to be general of cavalry in the course
of these ten years. His resolute leadership was conspicuous at
the battle of Peterwardein (1716) and he was soon
afterwards made commander of the Banat of Temesvár. At the great
battle of Belgrade (1717) he led the second line of left wing
cavalry in a brilliant and decisive charge which drove the Turks
from their trenches. After the peace he resumed the administration
of the Banat, which after more than 150 years of Turkish rule needed a humane and capable governor. But before his
work was done he was once more called away to a command in the
field, this time in southern Italy, where he fought the battle
of Francavilla (June 20, 1719), took Messina and besieged
Palermo. For eleven years more he administered the Banat,
reorganizing the country as a prosperous and civilized
community. In 1724 he made a general field marshal in the army,
but on the 29th of June was killed at the battle of Parma
while personally leading his troops. He left no children, and
his name passed to Corto Mercante, from whom came the
family of Mercy-Argentea (see below).

MERCY (adapted from Fr. merci, Lat. merces, reward, compassion, pardon, pity or forgiveness. The Latin word was
used in the early Christian ages for the reward that is given in
ten to those who have shown kindness without hope of return.
The French word, except in such phrases as Dieu merci, sans
merci, is primarily used in the sense of “thanks,” and is seen in the old English expression “gramerye,” i.e. grant merci,
great, many thanks, which Johnson took for “grant me mercy.”
In the medieval Church there were seven “corporate” and seven
“spiritual works of mercy” (opera meritoriae); these were
(a) the giving of food to the hungry and drink to the thirsty,
the clothing of the naked, the visitation of the sick and
of prisoners, the receiving of strangers, and the burial of the dead;
(b) the conversion of sinners, teaching of the ignorant, giving
of counsel to the doubtful, forgiveness of injuries, patience under
wrong, prayer for the living and for the dead. The order of
the Sires of Mercy is a religious sisterhood of the Roman Church.
It is found chiefly in England and Ireland, but there are branches
in the United States of America, in South Africa, in Bavaria America and in Aus-
mercury-Argenteau, FLOREMOND CLAUDE, COMTE DE
(1727-1794), Austrian diplomatist, son of Antoine, comte de
Mercy-Argenteau, entered the diplomatic service of Austria,
going to Paris in the train of Prince Kaunitz. He became
Austrian minister at Turin, at St. Petersburg, and in 1766 at Paris, where his first work was to strengthen the alliance between France and Austria, which was cemented in 1770 by the marriage of the dauphin, afterwards Louis XVI., with Marie Antoinette, daughter of the Empress Maria Theresa. When four years later Louis and Marie Antoinette ascended the throne, Mercy-Argen-

teau became one of the most powerful personages at the French court. He was in Paris during the turbulent years which heralded the Revolution, and his powerful aid was given first to

Loménie de Brienne, and then to Necker. In 1792 he became

governor-general of the Belgian provinces, which had just been reduced to obedience by Austria, and here his ability and experi-

ence made him a very successful ruler. Although at first in

favour of moderate counsels, Mercy-Argeteau supported the

action of Austria in making war upon his former ally after the

outbreak of the Revolution, and in July 1794 he was appointed

Austrian ambassador to Great Britain, but he died a few days

after his arrival in London.

See T. Juste, Le Comte de Mercy-Argeteau (Brussels 1865); A.

von Arneth and A. Geoffroy, Correspondances secrètes de Marie

Thérèse avec le comte de Mercy (Paris 1894); and A. von Arneth and

J. Flammermont, Correspondance secrète de Mercy avec Joseph II.

et Kaunitz (Paris 1889-1891). Mercy-Argeteau’s Correspondances

secrètes de Marie Thérèse has been condensed and translated into

English by Louis Sanski, and published under the title of A Guardian of

MERE. 1. (From Lat. merus, pure, unmixed; O. Fr. mier),

an adjective primarily indicating something pure and unmixed;

thus “mere wine” implied pure and unadulterated wine, as

“mere folly” expressed folly pure and simple. Modern usage has,

however, given both to the adjective “mere” and the

adverb “merely” a depreciatory and disparaging idea, so that

expressions like “the mere truth,” a “mere statement of fact,”

&c., often convey the impression that they are far from being

“mere” in the sense of “entire” or “absolute,” but are, on the

contrary, fragmentary of a larger whole. The word is retained in some legal phrases, especially in the phrase “mere motion,” that is, of one’s own initiative without help or

suggestion from the outside. Another legal phrase is “mere right” (law Latin jus merum), i.e. right without possession.

2. A word which appears in various forms in several Teutonic

and other languages; cf. Dutch and Ger. Meer. From the cognate

Lat. mare are derived the Romanic forms, e.g. Fr. mer, Span. mar,

&c.; the word appears also in the derivative “marsh” for

“marsh”; the ultimate origin has been taken to be an Indo-

European root, meaning “to lie,” i.e. to lie under the water, or,

indeed, the name given to lakes, pools and shallow stretches of water inland. In the Fen countries a mere signifies a marsh or a district

nearly always under water.

3. (Derived from an O. Eng. source, mare, a wall or

boundary; cognate with Lat. murus, a wall), a landmark or

boundary, also an object indicating the extent of a property

without actually enclosing it. A special meaning is that of a

road, which forms a dividing line between two places. A

“meresman” is an official appointed by parochial authorities to

ascertain the exact boundaries of a parish and to report

upon the condition of the roads, bridges, waterways, &c.,

within them. In the mining districts of Derbyshire a mere is a

certain measurement of land in which lead-ore is found.

MERE—MEREDITH

MEREDITH, GEORGE (1828-1909), British novelist and

poet, was born at Portsmouth, Hampshire, on the 12th of Feb-

ruary 1828; the parish church register records his baptism

on the 6th of April. About his early life few details are recorded,

but there is a good deal of quasi-autobiography, derived appar-

ently from early associations and possibly antipathies, in some of

his other novels, notably Evan Harrington and Harry Rich-

 mond, as to which the judicious may speculate. He had, as

he used to boast, both Welsh (from his father) and Irish blood

(from his mother) in his veins. His father, Augustine Armstrong

Meredith, was a naval outfitter at Portsmouth (mentioned as

such in Marryat’s Peter Simple); and his grandfather, Mel-

chisedek Meredith, clearly suggested the “Old Mel” of Evan

Harrington. Melchisedek was 35 when in 1796 he was initiated

as a freemason at Portsmouth; and he appears to have been known

locally as “the counsellor” because of a romantic story as an

antece ended at Bath; he was churchwarden in 1801 and

1804; and some of the church plate still bears his name.

Meredith’s mother died when he was three years old, and

he was made a ward in chancery. He was sent to school at

Newfield on the Rhine, and remained in Germany till he was

sixteen. During these impressionable years he imbibed a good

deal of the German spirit; and German influence, especially

through the media of poetry and music, can often be traced in

the cast of his thought and sentiment, as well as in some of the

intricacies of his life. Returning to England, he was engaged as

a solicitor in London, but he had little inclination

for the law, and soon abandoned it for the more congenial

sphere of letters, of which he had become an eager student.

At the age of twenty-one he began to contribute poetry to the

magazines, and he eked out a livelihood for some years by journalism, for the Daily News and other London papers, and for the Ipswich

Journal, for which he wrote leaders; a certain number of his more characteristic fugitive writings are collected in the memorial

edition of his works (1910). In London he became one of the

leading spirits in the group of young philosophical and

poetical radicals, which included most of those subsequent

leaders; Morley, Frederic Harrison, Cotter Morison and Admiral

Maxse. But during the years when he was producing his finest novels

he was practically unknown to the public. In 1849 he married

Mrs Nicholas, daughter of Thomas Love Peacock, the novelist,

a widow, eight years his senior, whose husband had been acciden-

tally drowned a few months after her first marriage (1844),

and who had one child, a daughter; but their married life was

broken by separation; she died in 1861, and in 1864 Meredith

married Miss Vulliamy, by whom he had a son and daughter.

His second wife died in 1885. Up to that time there is little to

record in the incidents of his life; he had not been “discovered”

except by an “honourable minority” of readers and critics.

It must suffice to note that during the Austro-Italian War of

1866 he acted as special correspondent for the Morning Post;

and though he saw no actual fighting, he enjoyed, particularly at

Venice, opportunities for a study of the Italian people which he

turned to account in several of his novels. Towards the close

of 1867, when his friend John Morley paid a visit to America,

Meredith undertook in his absence the editorship of the Fort-

nightly Review for Messrs Chapman & Hall. They were not only

literary essays, but a series of book-reviews and criticisms.

In their laboratory, as the capacity which he left a reputation for being

not only eminently wise in his selection of the books to be published,

but both critical and encouraging to authors of promise whose works he found himself obliged to reject. Thomas

Hardy and George Gissing were among those who expressed

their grateful sense of his assistance. He was indeed one of

the last of the old school of “publishers’ readers.” In his early

married life he lived near Weybridge, and later at Copsham

between Esher and Leatherhead, while soon after his second

marriage he settled at 11 Thut Cottage, Micklem, near Dorking,

where he remained for the rest of his life.

Meredith’s first appearance in print was in the character of a poet, and his first published poem “Chillian Wallah,”

may be found in Chambers’s Journal for the 7th of July 1849. Two

years later he put forth a small volume of Poems (1851),

which was at least fortunate in eliciting the praise of two judges

whose opinion was of the first importance to a beginner. Ten-

nison was at once struck by the individual flavour of the verse,

and declared of one poem, “Love in the Valley,” that he could

not get the lines out of his head. Charles Kingsley’s eulogy

was at once more particular and more particular. In Fraser’s

Magazine he subjected the volume to careful consideration,

praising it for richness and quaintness of tone that reminded

him of Herrick, for completeness and coherence in each separate

poem, and for the animating sweetness and health of the general

atmosphere. At the same time he censured the laxity of rhythm, the occasional lack of polish, and the tendency to
overload the description with objective details to the confusion of the principal effect. No doubt as a result of Kingsley's introduction, two poems by Meredith appeared in Fraser's Magazine shortly afterwards; but with the exception of these, and a sonnet in the Leader, he did not publish anything for the next five years. In the meanwhile he was busy upon his first essay in prose fiction. It was early in 1856 that the Shaving of Shagpat, a work of singular imagination, humour and romance, made its appearance. Modelled upon the stories of the Arabian Nights, it catches and action arche in the manner of Orientalism, and in this genre it remains a unique triumph in modern letters. Though unappreciated by the multitude, its genius was at once recognized by such contemporaries as George Eliot and Dante Gabriel Rossetti, the latter of whom was one of Meredith's intimate friends. For his next story it occurred to Meredith to turn his familiarity with the life and legendary tradition of the Rhinelander into a sort of imitation of the grotesquerie of the German romanticists, and in 1857 he put forth Farina, a Legend of Cologne, which sought to transfer to English sympathies the spirit of German romance. It was at one and the same time by his greatest effort in Oriental fairy-lore. The result was less successful. The plot of Farina lacks fibre, its motive is insufficient, and the diverse elements of humour, serious narrative, and romance scarcely stand in proportion to one another. But the Ordeal of Richard Feverel, which followed in 1859, transferred Meredith at once to a new sphere and to the altitude of his accomplishment. With this novel Meredith deserted the realm of fancy for that of the philosophical and psychological study of human nature, and Richard Feverel was the first, as it is perhaps the favourite, of those wonderful studies of motive and action which placed him among the demigods of English literature. The essential theme of this fine criticism of life is the question of a boy's education. It depicts the abortive attempt of a proud and opinionated father, hide-bound by theory and precept, to bring up his son to a perfect state of manhood through a "system" which controls all his early circumstances and represses many of the natural and wholesome instincts and impulses of adolescence. The love scenes in Richard Feverel are gloriously natural and full of vitality, and the book throughout marked a revolution in the English treatment of manly passion. Those who have not read by his original form, while the chapters which were afterwards omitted, have lost, however, the key to many passages in the story. In the following year Meredith contributed to Once a Week, and in 1861 published as a book the second of his novels of modern life, Eavan Harrington, originally with the subtitle "He Would be a Gentleman"—in allusion to the hero being the son of "Old Mel," the tailor—which contains a richly humorous—in its unrevised form, splendidly farcical—plot, with some magnificent studies of character. Afterwards revised, a certain amount of the farcical element was cut out, with the result that, considered as comedy, it has weak spots; but the Countess de Saldares remains a genuine creation. A year later he produced his finest volume of poems, entitled Modern Love, and Poems of the English Roadside, with Poems and Ballads. An attack upon the dramatic poem which gives the volume its title appeared in the Spectator, and is memorable for the fact that Meredith's friend, the poet Swinburne, with one of his characteristic generous impulses, replied (Spectator, June 7, 1862) in a spirit of fervent eulogy. Some of the individual "sonnets" (of sixteen lines) into which Modern Love is divided are certainly worthy of being ranked with the most subtle and most intense poetic work of the 19th century.

Returning to fiction, Meredith next published Emilia in England (1864), afterwards renamed Sandra Belloni. His powerful story Rhoda Fleming (1865) followed soon afterwards, Vittoria, published in the Fortnightly Review in 1866, and in book form in 1867, is a sequel to Emilia in England. Four years later appeared The Adventures of Harry Richmond in the pages of Cornhill (1870-1871). Its successor was Beauchamp's Career (Fortnightly Review, 1874-1875), the novel which Meredith usually described as his own favourite. Its hero's character is supposed to have been founded upon that of Admiral Maxse. Sondra Belloni, Rhoda Fleming, Vittoria and Beauchamp are all masterpieces of his finest period, rich in incident, character and workmanship. "The House on the Beach" and "The Case of General Opie and Lady Camper" (New Quarterly Magazine, 1877) were slight but glittering exercises in comedy; the next important novel was The Egoist (1879), which shows an increase in Meredith's twistedness of literary style and is admittedly hard to read for those who merely want a "story," but which has a certain charm and the real drama of the human spirit is an astounding production. In an interesting series of essays which Meredith delivered at the London Institution in 1877 his main thesis was that a man without a sense of comedy is dead to the finer issues of the spirit, and the conception of Sir Willoughby Patterne, the central figure of The Egoist, is an embodiment of this idea in the flesh. The Tragic Comedians (1880), the next of Meredith's novels, lighter in texture than his others, combines the spirits of comedy and tragedy in the story of the life of Ferdinand Lassalle, the German Socialist. Teaching of Earth (1888) gave further evidence of the wealth of thought and vigour of expression which Meredith brought to the making of verse. To "the general," no doubt, Meredith's verse is prohibitive, or nearly so—for, after all, he has written some poems, like "Martin's Puzzle," "The Old Chartist," and "Juggling Jerry," which anybody can read with ease. But his most characteristic style in verse is so concentrated that any one accustomed to straightforward writing, and unwilling to read with the mind rather than with the eye, must needs, to his loss, be put off. His readers, of the verse even more than of the prose, must be prepared to meet him on a common intellectual footing. When once that is granted, however, the music and magic of such poems as "Seed-time," "Hard Weather," "The Thrush in February," "The South-Wester," "The Lark Ascending," "Love in the Valley," "Melampus," "A Faith on Trial," are very real, amid all their occasional obscurities of diction.

Meredith had now completed his sixtieth year, and with his advancing years the angles of his individuality began to grow sharper, while the difficulties of his style became accentuated. The increase in mannerism was marked in One of Our Conquerors (1891), otherwise a magnificent rendering of a theme full of both tragedy and comedy, and in the poem of "The Empty Purse" (1893). Neither Lord Ormont and His Aminta (1894) nor The Amazing Marriage (1895) reached the level of the earlier novels, though in the latter he seemed to catch an afterglow of genius. In 1898 appeared his Odes in Contribution to the Song of French History, consisting of one ode ("France, December 1870") reprinted from Ballads and Poems (1871), and three others previously unpublished; a fine example of his lofty thought, and magnificent—if often difficult—and individual diction. In 1901 another volume of verse, A Reading
of Life, appeared. In later years too he contributed occasional poems to newspapers and reviews and similar publications, which were collected after his death (Last Poems, 1910). His last comedy, The Sentimentalists, was performed on the 1st of March 1910; his early but unfinished novel, Celt and Saxon, was also posthumously published in that summer.

From the early 'nineties onward Meredith's fame had been firmly established. His own literary contemporaries still living could join hands with the younger generation of enthusiastic admirers in insisting on a greatness of which they themselves had been unable to persuade the public. He was chosen to succeed Tennyson as president of the Authors' Society; on his seventieth birthday (1887) his portrait was presented with a congratulatory address by thirty of the thirty-three members of that body.

In various other ways his position as the chief living English writer had come to be popularly recognized. The critics discussed him; and new editions of his books (both prose and verse), for which there had long been but scanty demand, were called for. One of the results was that Meredith, with very doubtful wisdom, recast some of his earlier novels; and in the sumptuous "authorized edition" of 1887 (published by the firm of Constable, of which his son, William Lytton, was chief), many of the most prominent novels were made in some of them. In fact, a reader who compares the first and last editions either of Richard Feverel or Evan Harrington will notice changes little short of revolutionary.

Even in the previously current editions of 1878 onwards, published by Chapman & Hall, Richard Feverel had been considerably shortened as compared with the original three-volume edition; but it was now robbed again of some of its best-known passages. It is no doubt competent to an author himself to revise his earlier published work even to the extent to which Meredith did in the 1887 edition revised these novels; but certainly it is not necessary to accept his judgment when this involves the excision in old age of some of the most virile passages of books that were written in the full glow and vigour of his prime. In Constable's memorial edition (1910) of his complete works the excisions were published separately, and are therefore on record for those to consult who care. But the wise will read Richard Feverel and Evan Harrington in the original versions.

Meredith's literary quality must always be considered in the light of the Celtic side of his temperament and the peculiarities of his mental equipment. His nature was intuitive rather than rational; his mental processes were largely of the associative and far-reaching; and the suppression of connecting associations frequently gives his language, as it gave Browning's, but even to a greater extent, the air of an impenetrably nebulous obscurity. This criticism applies mainly to his verse, but is also true of his prose in many places, though there is much exaggeration about the difficulties of his novels. When once, however, his manner has been properly understood, it is seen to be inseparable from his method of invention. And to add to the narrative of description both vividness of delineation and intensity of realization, the essential respect in which Meredith's method of describing action and emotion in narrative differs from that of convention is that, while the ordinary method is to relate what happens from the point of view of the onlooker, Meredith frequently describes it from the point of emotion of the actor; and his influence in this direction has largely modified the art of fiction. 'Herein lies the secret of the peculiar brilliancy of his style, derived from his combination of the narrator with the creator, or—in its strict sense—the seer. The reader, by the transference of the interest from the audience to the stage, is carried into the very life and soul of the characters, so made to feel as he feels and act as he acts. Moreover, Meredith's instinct for psychology is so intimate, and his sense of motive and action so sure, that the interaction of character and character directly dominates the sequence of events depicted in his imaginary world, and discloses the moral idea or criticism of life, instead of the preconceived "moral" being merely illustrated by the plot. In building up the minds, actions, creeds, and tragedies or comedies of his imaginary personalities amid the selected circumstances, and inspiriting them with the identical motives and educational influences of life itself, Meredith spent an elaboration and profundity of thought and an originality and vigour of analysis upon his novels which in explicitness go far beyond what had previously been attempted in fiction, and which give to his works a philosophical value of no ordinary kind. Simplicity can scarcely be expected of his language, for the interplay of ideas is in itself original and complex, and their interpretation is necessarily original and complex too. But when Meredith is at his best he is only involved with the involutions of his subject; the aphorisms that Quinta, chief of the "Rede," utters when the ideal three may, simply, elaborate only in its elaboration. Pregnant, vividly graphic, capable of infinite shades and gradations, his style is a much finer and subtler instrument than at first appears, and must be judged finally by what it conveys to the mind, and by its superficial sound upon the conventional ear. It owes something to Jean Paul Richter; something, too, to Carlyle, with whose methods of narrative and indebtedness to the apparatus of German metaphysics it has a good deal in common. To the novelist Richardson, too, a careful reader will find that Meredith, both in manner and matter (notably in Crome Yellow and Egoist) has paid a debt. In "Mrs Grandison" in Richard Feverel he even recalls "Sir Charles Grandison" by name; and nobody can doubt that Sir Willoughby Patterne, both in idea and often in expression, was modelled on Richardson's creation. Careful students of the early 19th-century English novel will find curious echoes again in Meredith of Bulwer-Lytton's (Baron Lytton's) literary manner and romantic outlook. But he was, after all, an originator, and at first suffered in estimation on that score; he wrote in his own way, and what is most characteristic of his style is "simple" when the ideal three like the great masters, he has his own tone of voice, his own fashion of expressing an idea. Feeling, perception, reflection, judgment, have equal shares in determining his architectonic relation to a problem or a situation. He rings changes on the changing emotions of humanity, but every chimne rings true. He is a literary actor. He takes great themes, not little ones; the characters in his fiction are personalities, human beings, neither "heroes" nor "sports"; and he does not descend to pander to luridity or cater for the "reading public." His gallery of portraits of real human women, not dolls, would alone place him in the front rank of English literature.

It is beyond our scope here to enter into details concerning the philosophy which represents Meredith's "criticism of life." Broadly speaking, it is a belief in the righteousness and wholesomeness of nature, when Nature—"Sacred Reality"—is lovingly and faithfully and trustfully sought and known by the pure use of reason. Man must be "obedient to Nature, not her slave." Mystical as this philosophy occasionally becomes, it is yet an inspiring one, clean, austere and practical; and it is always dominated by the categorical imperative of self-knowledge and the striving after honesty of purpose and thought. A strong vein of political Radicalism runs through Meredith's creed. It is, however, a Radicalism allied to that of the French philosophes, rather than to the contemporary developments of British party politics, though in later life he gave his open support to the Liberal party. In spite of his German upbringing Meredith was always strongly French in his sympathies, and his appreciation of French character at its best and at its worst is finely shown in his Napoleon odes. In the main his politics may be summed up as a striving after liberty for reason and conscience and the constant progress of humanity—

The cry of the conscience of life;
Keep the young generations in hail,
And beget them no tumble house.

1 The fact that Bulwer-Lytton's son, the 1st Earl of Lytton, Meredith's junior by three years, took the pen-name of "Evan Meredith," led occasionally to some confusion among uninstructed contemporaries, and even the suggestion of a family connexion.
MEREJKOVSKY—MERGANSER

It is part of Meredith’s philosophy—and this must be remembered in considering his dictum—that verbal expression is itself a part of right thought and action. Hence is derived his passion for verbal analysis. Hence also his impulse towards and vindication of poetry—meaning still “the best words in the best order”; and hence his own dictum, otherwise perhaps hard to undiscerning minds, that Song itself is the test by which truth may be tried. The passage occurs in “The Empty Purse”—a poem which throughout is a careful though mannered exposition of Meredith’s general views on life—

Ask of thyself: This varous Yea
A speech I think to recite.
In the cause I would have prevail,
For seed of a nourishing wheat,
Is it accepted of Song?
Does it sound to the mind through the ear,
Right sober, pure sane? has it disciplined feet?
Thou wilt find it a test severe;
Unerring whatever the theme.
Rings it for Reason a melody clear,
We have bidden old Chaos retreat,
We have called on Creation to hear;
All forces that make use of one full stream.

Meredith is generally ranked far less high as a poet than as a novelist. But he can only be understood and appreciated properly by those who realize that not prose (in the ordinary sense) but poetry was to him the highest form of expression, and that only in it could he fully deliver his message, as a writer who aspired to contribute something more to the common stock of ideas than could be embodied dramatically in prose fiction.

On Meredith’s 80th birthday in 1908, the homage of the English literary world was again paid in an address of congratulation. But his health, which for many years had been precarious, was now failing. He died at Flint Cottage, Box Hill, Surrey, on the 18th of May 1909. A strong feeling existed that he should be buried in Westminster Abbey, and a petition to that effect, which was approved by the prime minister, Mr Asquith, was signed by a large number of men of letters. But this was not to be. A memorial service was held in the abbey, but Meredith’s own remains, after cremation, were interred at Dorking by the grave of his second wife. He had died only a brief span after his old friend Swinburne, his affection for whom had never clouded and above all, it was felt that with the great epoch in English literary history had closed. They were the last of the great Victorians; and in Meredith went the writer who had raised the creative art of the novel, as a vehicle of character and constructive philosophy, to its highest point—a point higher indeed than most contemporary readers were prepared for. The estimate of his genius formed by “an honourable minority,” who would place him in the highest class of all, by Shakespeare, has yet to be confirmed by the wider suffrage of posterity.

A carefully compiled bibliography by John Lane was included in George Meredith: Some Characteristics, by R. Le Gallienne (1906). This sympathetic essay in criticism was the first substantial publication addressed to that stimulation of a wider appreciation of Meredith which was carried out by several later books, perhaps the best of which is M. Sturge Henderson’s George Meredith: Novelist Poet, Reformer (1908); but such earlier testimonies to Meredith’s importance as Julian McCarthy’s, in his History of Our Own Times, must not be overlooked. Also J. R. Lechman, George Mer- dith in Anecdotes and Criticism (1909). (H. Cbl.)

MEREJKOVSKY (or Merezhkovsky), Dmitri Sergeyevich

(1865— ), Russian novelist and critic, was born at St Petersburg in 1865. His trilogy of historical romances, collectively entitled Christ and Antichrist, has been translated into many European languages, notably English and French. It comprises Smert Bogoy (Eng. trans. “The Death of the Gods,” London, 1901), the central figure in which is Julian the Apostate; Voskresenie Bogi (“The Resurrection,” London, 1902), which describes the life and death of Leonardo da Vinci; and Antikkristi Piet i Aleksey (“Peter and Alexis,” London, 1905), which is based on the tragic story of the relations between Peter the Great and his son. The influence of Sienkiewicz can be traced in many of Merezhkovsky’s writings, which include critical studies of Pliny the Younger, Calderon, Montaigne, Ibsen, Tolstoy (Tolstoy as Man and Artist, London, 1902), and of Gorki and other Russian writers. Merezhkovsky married Zinaida Nikolayeva, known in Russia for her poems, essays and short stories written under the pseudonym of Zinaida Hippius (or Gippius); her collected poems (1889-1903) were published in Moscow in 1904.

MERES, Francis (1562-1647), English divine and author, was born at Kirton in the Holland division of Lincolnshire in 1565. He was educated at Pembroke College, Cambridge, where he graduated B.A. in 1587, and M.A. in 1591. Two years later he was incorporated M.A. of Oxford. His kinsman, John Meres, was high sheriff of Lincolnshire in 1596, and apparently helped him in the early part of his career. In 1602 he became rector of Wing in Rutland, where he had a school. He died on the 29th of January 1647. Meres rendered immense service to the history of Elizabethan literature by the publication of his Palladis Tamia, Wits Treasury (1598). It was one of a series of volumes of short pithy sayings, the first of which was Politeiahus Wits Commonwealth (1597), compiled by John Bodenham or by Nicholas Ling, the publisher. The Palladis Tamia contained moral and critical reflections borrowed from various sources, and embraced sections on books, on philosophy, on music and painting, and a famous “Comparative List of our English poets with the Greek, Latin, and Italian poets.” This chapter enumerates the English poets from Chaucer to Meres’s own day, and in each case a comparison with some classical author is instituted. The book was issued in 1634 as a school book, and has been partially reprinted in the Ancient Critical Essays (1811-1815) of Joseph Haslewood, Professor E. Arber’s English Garner, and Gregory Smith’s Elizabethan Critical Essays (1904). A sermon entitled Gods Arithmetick (1597), and two translations from the Spanish of Luis de Granada entitled Granados Denomination and the Sinners Guide (1598) completed the list of his works.

MERGANSER, a word due to C. Gesner (Hist. animalium lii., 1555), and for long used in English as the general name for a group of fish-eating ducks possessing great diving powers, and forming the genus Mergus of Linnaeus, now regarded by ornithologists as a sub-family, Merginae, of the family Anatidae. The mergansers have a long, narrow bill, with a small but evident hook at the tip, and the edges of both mandibles beset by numerous horny denticulations, whence in English the name of saw-bill is frequently applied to them. Otherwise their structure does not much differ from other diving ducks; all the species bear a more or less developed crest or tuft on the head. Three of them, Mergus merganser or castor, M. serra- tor, and M. albellus, are found over the northern parts of the Old World, and of these the first two also inhabit North America, which has besides a fourth species, M. cucullatus, said to have occasionally visited Britain. M. merganser, commonly known as the goosander, is the largest species, being nearly as big as the smaller geese, and the adult male in breeding-attire is a very beautiful bird, conspicuous with his dark glossy-green head, rich salmon-coloured breast, and the upper part of the body and wings black and white. This full plumage is not assumed till the second year, and in the meantime, as well as in the post-nuptial dress, the male much resembles the female, having, like her, a reddish-brown head, the upper parts grey and the lower white. In this condition the bird is often known as the “dun diver.” This species breeds abundantly in many parts of Scandinavia, Russia, Siberia and North America, and occasionally in Scotland. M. serrator, commonly called the red-breasted merganser, is a somewhat smaller bird; and, while the fully-dressed male wants the delicate hue of the lower parts, he has a gorget of russet mottled with white, below which is a patch of white feathers, broadly edged with black. Both these species have the bill and feet of a bright reddish-orange, while the much smaller M. albellus, known as the smew, has these parts of a lead colour, and the breeding plumage of the adult male is white, with quaint crescentic markings of black, and the flanks most beautifully variegated.
MERGENTHEIM—MERIAN

M. cucullatus, the hooded merganser of North America, is in size intermediate between \(M. \) alellus and \(M. \) serrator; the male is easily recognizable by his broad semicircular crest, bearing a fan-shaped patch of white, and his elongated subcapulars of white edged with black. The conformation of the trachea in the male of \(M. \) merganser, \(M. \) serrator and \(M. \) cucullatus is very like that of the ducks of the genus \(Clongula, \) but \(M. \) cucullatus has less exaggerated development more resembling that of the ordinary \(Fuligula. \) From the southern hemisphere two species of \(Mergus \) have been described, \(M. \) octosceous or \(M. \) brasilius, L. P. Vieillot (\(V. \) dict. d'Hist. naturelle, ed. 2, vol. xiv. p. 222; \(Gal. \) des oiseaux, tom. ii. p. 209, pl. 283), inhabiting South America, of which but few specimens have been obtained, having some general resemblance to \(M. \) serrator, but much more darkly coloured, and \(M. \) australis, Hombron and Jacobemont (\(Ann. \) sc. nat. zoologie, ser. 2, vol. xvi. p. 320; \(Voy. \) au P\(\) l Sud, oiseaux, pl. 31, fig. 2), known only by the unique example in the Paris Museum procured by the French Antarctic expedition in the Auckland Islands.

Often associated with the mergansers is the genus \(Merganetta, \) the so-called torrent-ducks of South America, of which six species have been described; but they possess spiny tails and have their wings armed with a spur. These with \(Hymenolecanus Malacorhynchus, \) the blue duck of New Zealand, and \(Salvadorina waiguenis \) of Waigiu are placed in the sub-family \(Merganellinae. \)

(\(A. \) N.)

MERGENTHEIM, a town of Germany, in the kingdom of Württemberg, situated in the valley of the Tauber, 7 m. S. from Lauda by rail. Pop. (1860), 4,335. It contains an Evangelical and three Roman Catholic churches, a Latin and other schools, and a magnificent castle with a natural history collection and the archives of the Teutonic order. This is now used as barracks. The industries of the town include tanning, the manufacture of agricultural machinery and wine-making. Near the town is a medicinal spring called the Karlsbad.

Mergentheim (\(Mariea dominus)\) is mentioned in chronicles as early as 1598, as the residence of the family of the counts of Hohenlohe, who early in the 13th century assigned the greater part of their estates in and around Mergentheim to the Teutonic order. It rapidly increased in fame, and became the most important of the eleven commanderies of that society. On the secularization of the Teutonic Order in Prussia in 1525, Mergentheim became the residence of the grand master, and remained so until the final dissolution of the order in 1809. See \(Höring, \) \(Das Karlsbad bei Mergentheim (Mergentheim, 1887); \) and \(Schmitt, \) \(Garnisongeschichte der Stadt Mergentheim (Stuttgart, 1895).\)

MERGER (\(Fr. \) merger, to sink), in law, the sinking or "drowning" of a lesser estate in a greater, when the two come together in one and the same person without any intervening estate. In order to effect a merger the two estates must vest in the same person at the same time, must be immediately expected one on the other, and the expectant estate must be larger than the preceding estate. The term is also used for the extinguishment of any right, contract, &c., by absorption in another, e.g. the acceptance of a higher security for a lower, or the extinguishing of a simple contract in a deed.

MERGUI, the southernmost district of Lower Burma, in the Tenasserim division, bounded on the W. by the Bay of Bengal and on the E. by Siam. Area 9780 sq. m. Two principal ranges cross the district from north to south, running almost parallel to each other for a considerable distance, with the Tenasserim river winding between them till it turns south and flows through a narrow rocky gorge in the westernmost range to the sea. The whole district, from the water's edge to the loftiest mountain on the eastern boundary, may be regarded as almost unbroken forest. The timber trees found towards the interior, and on the higher elevations, are of great size and beauty, the most valuable being teak (\(Tectona grandis), \) then-pan (\(Hopea odorata), \) ko-nyyeng (\(Dipterocarpus laricis), \) &c. The coast-line of the district, off which lies an archipelago of two hundred and seven islands, is much broken, and for several miles inland is very little raised above sea-level, and is drained by numerous muddy tidal creeks. Southwards of Mergui town it consists chiefly of low mangrove swamps alternating with small fertile rice plains. After passing the mangrove limits, the ground to the east gradually rises till it becomes mountains, even to the peaks of the rivers, and finally culminates in the grand natural barrier dividing Burma from Siam. The four principal rivers are the Tenasserim, Le-nya, Pakchan and Palaau, the first three being navigable for a considerable distance. Coal is found on the banks of the Tenasserim and its tributaries, but is still unworked. Gold, copper, iron and manganese are also found in various parts of the district, and there are tin mines at Mallun, upon which European methods have been tried without much profit, owing to the cost of labour.

From the notion of early travellers it appears that Mergui, when under Siamese rule, before it passed to the Burmese, was a rich and densely peopled country. On its occupation by the British in 1824-1825 it was found to be almost depopulated —the result of border warfare and of the cruelties exercised by the Burmese conquerors. At that time the entire inhabitants numbered only 10,000. It had a population of 88,744 in 1901, showing an increase of 20% in the decade and giving a density of 9 inhabitants to the sq. m. Mergui carries on a flourishing trade with Rangoon, Bassein and the Straits Settlements. The chief exports consist of rice, rattans, torches, dried fish, areca-nuts, sesame seeds, molasses, sea-shells, edible birds' nests and tuna. The staple imports are piece goods, tobacco, cotton, earthenware, tea and sugar. The climate is remarkably healthy, the heat due to its tropical situation being moderated by land and sea breezes. The rainfall is very heavy and usually exceeds 150 inches.

Mergui town has risen into prominence in recent years as the centre of the pearl-fishing trade in the neighbouring archipelago. The pearling grounds were practically unknown in 1880, but in the following decade they produced pearls and mother-of-pearl of considerable value. In 1901 the population was 11,987; but the census is taken at a time when many of the fishermen and their families are away in the islands. There is a considerable coasting trade with other Burmese and with the Straits Settlements.

MERGUI ARCHIPELAGO, a cluster of islands in the Bay of Bengal, near the southern coast of Lower Burma. They are chiefly noted for their picturesque beauty, some of them rising to 3000 ft. They are only sparsely inhabited by the island race of Selungas.

MERIAN, MATTHEW (1593-1650), Swiss engraver, was born in Basel, on the 25th of September 1593. The family came originally from near Delémont, but in his grandfather's time settled in Basel, where in 1553 it obtained the burgesship of the city. As Matthew early showed signs of artistic tastes, he was placed (1609) under the care of Dietrich Meyer, a painter and engraver of Zürich (1572-1658). He went on to Nancy in 1613, where he already displayed considerable talents as an engraver on copper. After studying in Paris, Stuttgart (1616) and the Low Countries, he came to Frankfurt, where in 1618 he married the eldest daughter of J. T. de Bry, who was a publisher and bookbinder as well as arrowsmith. Merian worked for some time with his father-in-law in Oppenheim, and then returned to Basel, whence he came back (1624) to Frankfurt after Bry's death (1623), in order to take over his business;

tempests and of the colossal wall which encircled the city, besides a Roman triumphal arch, commonly called the Arc de Santiago, and a second Roman bridge, by which the road to Salamanca was carried across the small river Albarregas (Alba Regia). The Moorish alcazar or citadel was originally the chief Roman fort. From the Lago de Proserpina, or Charca de la Albueara, a large Roman reservoir, 3 m. north, water was conveyed to Mérida by an aqueduct, of which 37 enormous piers remain standing, with ten arches in three tiers built of brick and granite. The massive Roman theatre is in good preservation; there are also a few vestiges of an amphitheatre and of a circus which measured 485 yds. by 120. Other Roman remains are exhibited in the archaeological museum, and much Roman masonry is incorporated in the 16th century Mudéjar palace of the dukes of La Roma, the palace of the counts of Los Corbos, and the concert of Santa Eulalia, which is said by tradition to mark the spot where St Eulalia was martyred (c. 300).

Augusta Emerita was founded in 25 B.C. As the capital of Lusitania it soon became one of the most splendid cities in Iberia, and was large enough to contain a garrison of 90,000 men. Under the Visigoths it continued to prosper, and was made an archbishopric. Its fortifications included five castles and fourteen gateways; but after stubborn resistance it was stormed by the Moors in 1113. Its Moorish government, however, and sometimes successfully, asserted its independence, but Mérida was never the capital of any large Moorish state. In 1129 its archbishopric was formally transferred to Santiago de Compostela, and in 1228, when Alphonso IX. of Leon expelled the Moors, Mérida was entrusted to the order of Santiago, in whose keeping it soon sank into decadence.

MERIDIAN, a city of New Haven county, Connecticut, U.S.A., in the township of Meriden, S.W. of the centre of the state, about 18 m. N.N.E. of New Haven, and about the same distance S.S.W. of Hartford. Pop. of the township, 27,265 (1910), 28,695; (1910), 32,066; of the city (1900), 24,296, of whom 7,215 were foreign-born; (1910), 27,265. Meriden is served by the New York, New Haven & Hartford railway and by an inter-urban electric line. The city is bisected by Harbor Brook, a small stream, and through the S.W. part of the township flows the Quinnipiac river. A short distance N.W. of the city, in Hubbard Park, an attractive reservation of more than 900 acres, are the Hanging Hills, three elevations (West Mountain, South Mountain and Cat-Hole Mountain) in a broken range of trap ridges, which have resisted the erosion of the Connecticut lowlands of the Connecticut valley; they rise to a height of about 700 ft. above the sea. In their vicinity, near the boundary of Berlin township, is Merimeere, one of the city's four reservoirs. Meriden is the seat of the Connecticut School for Boys (Reformatory). There are also a public library (1899), a state armoury, a hospital, the Curtis Home for orphans and aged women, and a tuberculosis sanitarium supported by the city. Meriden is one of the most important manufacturing cities of Connecticut, and in 1905 produced 59-9% of the plated ware manufactured in the state, and much sterling silver. In 1905 the factory product was valued at $13,763,548, an increase of 17-1% over that of 1900. Meriden was originally a part of the township of Wallingford, but a tract in the northern part of this township was designated as Meriden by an Indian deed of 1664. It was made a separate parish under that name in 1728, but did not become a separate township until 1806. The city was chartered in 1867.

See G. W. Perkins, Historical Sketches of Meriden (West Meriden, 1849); C. H. S. Davis, History of Wallingford (Meriden, 1870), South Meriden and C. Bancroft Gillespie, A Century of Meriden (Meriden, 1906).

MERIDIAN, a city and the county-seat of Lauderdale county, Mississippi, U.S.A., about 90 m. E. of Jackson. Pop. (1890), 10,624; (1900), 12,050, of whom 578 were negroes; (1910 census), 23,285. It is served by the Southern, the Alabama Great Southern, the Mobile & Ohio, and the New Orleans & North Eastern and the Alabama & Vicksburg (Queen &...
Crescent Route) railways. It is the seat of the East Mississippi Insane Hospital, of the state Masonic Widows and Orphans' Home, and of the Meridian Female College, which opened in 1903, the Meridian Male College (opened in 1901), and, for negroes, the Lincoln School (Congregational) and Meridian Academy (Methodist Episcopal). The city is an important market for cotton grown in the surrounding country, and is the principal manufacturing city in the state. Its factory products, chiefly railway supplies and cotton products, increased in value from $1,924,465 in 1900 to $3,267,600 in 1905, or 69.8% in five years. Mineral waters (especially lithia) are bottled in and near the city. Meridian was laid out in 1854 at the point where the Mobile and Ohio crossed the Mississippi as a city in 1860. In February 1864 General William T. Sherman, with an army of about 20,000, made an expedition from Vicksburg to Meridian, then an important railway centre and dépôt for Confederate supplies, chiefly for the purpose of making inoperative the Mobile & Ohio and the Jackson & Selma railways; on the 14th of the month his army entered Meridian, and within a week destroyed nearly everything in the city except the private houses, and tore up over 110 m. of track.

In the "Meridian riot" of 1871—a prominent episode of reconstruction—of several months' duration mob violence had shot the presiding judge, the whites, especially those of the lower class, having formed a party from Alabama interested in the trial, killed a number of negroes and burned a negro school. On the 2nd of March 1906 a cyclone caused great loss of life and property.

**MERIDIAN** (from the Lat. meridianus, pertaining to the south or mid-day), in general a direction toward the south or toward the position of the sun at mid-day. The terrestrial meridian of a place is the great circle drawn on the earth's surface from either pole through the place. As determined astronomically the celestial meridian is the great circle passing through the pole on the earth's surface. The terrestrial meridian as practically determined is the circle on the earth's surface in which the plane of the celestial meridian cuts that surface. Owing to local deviations of the plumb-line the meridian thus determined does not strictly coincide with the terrestrial meridian as ordinarily defined, but the deviation, though perceptible in mountainous regions, is so minute that it is generally ignored.

**MÉRIMÉE, PROSPER** (1803-1870), French novelist, archaeologist, essayist, and in all these capacities one of the greatest men of his age and century. He was born in Paris on the 28th of September 1803. His grandfather, of Norman abstraction, had been a lawyer and steward to the maréchal de Broglio. His father, Jean François Léonard Mérimée (1753-1836), was a painter of repute. Mérimée had English blood in his veins on the mother's side, and had English proclivities in many ways. He was educated for the bar, but entered the public service instead. A young man at the time of the Romantic movement, he felt its influence strongly, though his peculiar temperament prevented him from joining any of the coteries of the period. Nothing was more prominent among the Romantics than the fancy, as Mérimée himself puts it, for "local colour," the more unfamiliar the better. He exhibited this in an unusual way. In 1825 he published what purported to be the dramatic works of a Spanish lady, Clara Gazul, with a preface stating circumstantially how the supposed translator, one Joseph L'Estrange, had met the gifted poetess at Gibraltar. This was followed by a still more audacious and still more successful supercherie. In 1827 appeared a small book entitled la Gazela (the anagram of Gazul), and giving itself out as translated from the Illyrian of a certain Hyacinthe Maglano, this book, which has greater formal merit than Clara Gazul, is said to have taken in Sir John Bowring, a competent Slav scholar, the Russian poet Poushkin, and some German authorities, although not only had it no original, but, as Mérimée declares, a few words of Illyrian and a book or two of travels and topography were the author's only materials. In the next year appeared a short dramatic romance, La Jacquerie, in which is visible Mérimée's extraordinary faculty of local and historical colour, his command of language, his grim irony, and a certain predilection for tragic and terrible subjects, which was one of his numerous points of contact with the men of the Renaissance. This in its turn was followed by a still better piece, the Chronique de Charles IX. (1829), which stands perhaps towards the 16th century more than the Jacquerie does towards the middle ages. All these works were to a certain extent second-hand. But they exhibited all the future literary qualities of the author: the two chiefest, his wonderfully severe and almost classical style, and his equally classical solidity and statuesqueness of construction.

He had already obtained a considerable position in the civil service of the French government by the time he was 28, and was chartered with the chancery of the French Senate to two different ministers. He was then appointed to the more congenial post of inspector-general of historical monuments. Mérimée was a born archaeologist, combining linguistic faculty of a very unusual kind with accurate scholarship, with remarkable historical appreciation, and with a sincere love for the arts of design and construction, in the former of which he had some practical skill. In his official capacity he published numerous reports, some of which, with other similar pieces, have been republished in his works. He also devoted himself to history proper during the latter part of the 19th century, and the fully monarchy, and published some important essays and works of correspondence, partly on Spanish, Russian and ancient Roman history. He did not, however, neglect novel writing during this period, and numerous short tales, almost without exception masterpieces, appeared, chiefly in the Revue de Paris. The best of all, Colomba, a Corsican story of extraordinary power, appeared in 1840. He travelled a good deal; and in one of his journeys to Spain, about the middle of Louis Philippe's reign, he made an acquaintance destined to influence his future life not a little—that of Mme de Montijo, mother of the future empress Eugénie. As he was, however, through the manner and language the most cynical of men, was a devoted friend, and shortly before the accession of Napoleon III. he had occasion to show this. His friend, Libri Carucci dalla Sommaja, was accused of having stolen valuable manuscripts and books from French libraries, and Mérimée took his part so warmly that he was actually sentenced to and underwent fine and imprisonment. He had been elected of the Academy in 1844, and also of the Academy of Inscriptions, of which he was a prominent member. Between 1843 and 1850 he wrote more tales, the chief of which were Arisbe Guillot (1847), last year, a Spanish subject, hardly ranking below Colomba.

The empire made a considerable difference in Mérimée's life. His sympathies were against democracy, and his habitual cynicism and his irreverent prejudices made legitimism distasteful to him. But the marriage of Napoleon III. with the daughter of Mme de Montijo at once enlisted what was always strongest with Mérimée—the sympathy of personal friendship—on the emperor's side. He was made a senator, but his most important rôle was that of a constant and valued private friend of both the "master and mistress of the house," as he calls the emperor and empress in his letters. He was occasionally charged with a kind of irregular diplomacy, and once, in the matter of the emperor's Caesar, he had to give literary assistance to Napoleon. But for the most part he was strictly l'ami de la maison. At the Tuileries, at Compiègne, at Biarritz, he was a constant though not always a very willing guest, and his influence over the empress was very considerable and was fearlessly exerted, though he used to call himself, in imitation of Scarron, "le bouillon de sa majesté." He found, however, time for not a few more tales, of which more will be said presently, and the correspondence, which is not the least of his literary achievements, while they have an extraordinary interest of matter. One of these consists of the letters which have been published as Lettres à une inconnue, another of the letters addressed to Sir Anthony Panizzi, librarian of the British Museum. After various conjectures it seems that the inconnue just mentioned was a certain Mlle Jenny Daquin of Boulouge. The acquaintance extended over many
years; it partook at one time of the character of love, at another of that of simple friendship, and Mérimée is exhibited in the letters under the most surprisingly diverse lights, most of them more or less amiable, and all interesting. The correspondence with Panizzi has somewhat less personal interest. But Mérimée often visited England, where he had many friends (among whom the late Mr Ellice of Glengarry was the chief), and certain similarities of taste drew him closer to Panizzi personally, while during part of the empire the two served as the channel for a kind of unofficial diplomacy between the imperial and certain English statesmen. These letters are all of a shrewd aperçu on the state of Europe at different times. Both series, and others since published, abound in gossip, in amusing anecdotcs, in sharp literary criticism, while both contain evidences of a cynical and Rabelaisian or Swiftian humour which was very strong in Mérimée. This characteristic is said to be so prominent in a correspondence with another friend, which now lies in the library at Avignon, that there is but little chance of its ever being printed. A fourth collection of letters, of much inferior extent and interest, has been printed by Blaze de Bury; and the title of Lettres à une autre inconnue (1873), and others still by d'Haussonville (1888), and in the Revue des Deux Mondes (1896). In the latter years of his life Mérimée suffered very much from ill-health. It was necessary for him to pass all his winters at Cannes, where his constant companions were two aged English ladies, friends of his mother. The Terrible Year found him completely broken in health and anticipating the worst for France. He lived long enough to see his fears realized, and to express his grief in some last letters, and he died at Cannes on the 23rd of September 1870.

Mérimée's character was a peculiar and in some respects an unfortunate one, but by no means unintelligible. Partly by temperament, partly it is said owing to some childish experience, when he discovered that he had been duped and determined never to be so again, not least owing to the example of Henri Béyle (Stendhal), who was a friend of his family, and of whom he saw much, Mérimée appears at a comparatively early age to have imposed upon himself as a duty the maintenance of an attitude of sceptical indifference and sarcastic criticism. Although a man of singularly warm and affectionate feelings, he obtained the credit of being a cold-hearted cynic; and the title of Lettres à une autre inconnue (1873), and others still by d'Haussonville (1888), and in the Revue des Deux Mondes (1896). of the mutton while sacrificing to some extent that of the wool.

The merino sheep appears to have originated in Africa, whence it was brought by the Moors to Spain and thence spread over Europe, especially to Austria-Hungary, Germany and France. The best-known breeds are the Rambouillet, a large merino named after the village near Paris, to which it was imported towards the end of the 18th century, and the Negretti, which stands in closer relationship to the old Spanish stock and has shorter wool but a more wrinkled fleece. Importations to America began about the beginning of the 19th century. The so-called American merino, the Delaine, the Verme and the Rambouillet, are well-known breeds in the United States.

The term "merino" is widely employed in the textile industries with very varied meanings. Originally it was restricted to denote the wool of the merino sheep reared in Spain, but owing to the superiority of the wool grown on merino sheep and shipped from Botany Bay, the name as applied to wool was replaced by the term "botany." In the dress-goods and knitting trades the term "merino" still implies an article made from the very best soft wool. The term "cashmere," however, is frequently confused with it, although the goods should be made from true cashmere and not, as is often the case, the coarsest botany wool. In the hosiery and remanufactured materials trades the term "merino" is applied to fibre-mixtures of cotton and wool in contradistinction to "all wool" goods.

**MERIONETH** (Welsh, Merionydd), a county of North Wales, bounded N. by Carnarvon and Denbigh, E. by Denbigh and Montgomery, S.E. by Montgomery, S. by the Dovey (Dyfi) estuary, dividing it from Cardigan, and W. by Cardigan Bay. It is nearly triangular, its greatest length from N.E. to S.W. being about 45 m., its greatest breadth about 30 m. The relief is less bold than that of Carnarvon, but the scenery is richer and more picturesquely varied. The highest summits are the peaks of Cadair Idris (q.v.) including Pen y gader (the head of the chair; 9297 ft.); Aran Fawddwy (9297 ft.); Arenig fawr (2600 ft.); Y Llethr (2475 ft.), and Rhobell fawr (2313 ft.). Perhaps the finest of the valleys are those of Dyfi (Dovey) Dywyni, Tal y llyn (forehead of the lake), Maw (Mawddach), and Festiniog. The Dyfrdwy (Dyfi) drains the Bala Lake (Llyn Tegid or Plynlimon), which is fed by the brooks rising at the foot of Cadair Idris. The Dyfrdwy, Lledr, and Dee (or Dwyryd) streamlet form the W. limit of the Cambrian uplands, and expands into an estuary of Cardigan Bay. Rising north of the Aran, the Mawddach (Maw) runs south-west some 12 m., being joined by rivulets. Traeth bach is formed by the Dwyryd streamlet among others. Other streams are the Uwion, Eden, Cain (variously spelled), besides Bala and Tal y llyn lakes, there are among the hills over fifty more, e.g. Llyn Mywngyl. Among the waterfalls may be mentioned Rhaiadr y lyn (cascade of the glen), near Corwen, Rhaiddr y (black), and Pistyll Cain (Cain's waterspout), some 150 ft. high.

A mountain tract of the county, 15 m. from north to south by 10 from east to west, stretching from the coast inland, is of the Cambrian age, composed of grits, quartzites and slates, and comprising the Merionethshire antickill. The central portion of this tract is occupied mainly by Harlech Grits and Menayan beds; it is only 60 m. wide, east and west, and 120 m. north and south. The Redmaroc and Arenig beds, which are pierced by numerous dikes and intrusive masses, mostly greenstone. The andesitic rock of Rhodell-fawr is one of the greatest igneous masses in the county. The Lingula beds are quarried and mined for slate at Festiniog, and near Dolgelly gold is obtained from a quartz vein, while near Barmouth manganese has been worked. Bordering the Cambrian area are the Llanfawr limestone hills. The Arenigs, Manod and Moelwyn; and these are in turn overlaid by the Llandello and Bala beds, the latter including the Bala limestone. Lead and copper ores have been worked near Towy.

Here and there along the eastern boundary Llandover and Wenlock strata are included. The structure of the Silurian tract is synclinal; in the Berwyn mountains the Ordovician rocks again appear associated andesitic and felsic lavas and tuffs. West of Llanwrin, near Corwen, is a small patch of Carboniferous limestone. Glacial drift with bowlder clay is a prominent feature in the valleys and on the mountain sides. A good deal of blown sand fringes the coast and south of Harlech. At the Llyn Arenig Bach a deposit of kieselsugar has been found.

The climate varies much with the elevation, from bleak to genial, as at Aberdyfi (Aberdovey). Grain crops cover a small area only, green crops being poor, and fruits practically nil. While the soil is generally thin, there are fertile tracts in the valleys, and there is some reclaimed land. The small, hardy ponies (known as of Llanbadar, Conway Valley) are now almost restricted to this county and Montgomeryshire. Manufactures include woollen stockings, &c., at, and near Bala, flannels at Dolgellau (Dolgelly), and, a few other places. Slate is the chief staple. The Cambrian railway skirts the coast from Portmadoc to Aberdyfi. At Barmouth junction a branch crosses to Dolgelly, where it is joined by a branch of the Great Western railway. Bala and Festiniog are also united by the Great Western, and Festiniog is further joined with Llandudno junction by the London & North Western railway, and with Portmadoc (Minford) by the narrow gauge railway, a light line, from a junction in 1895, running through the centre of the county, and for nearly 700 ft. in the tourist traffic is a source of livelihood to many of the inhabitants. The coast is almost unavailing, owing to sand-banks, and the only havens are Barmouth and Aberdyfi.

The area of the ancient county is 427,810 acres or 676 sq. m., with a population in 1891 of 49,212 and 1901 of 49,149. In the 19th century, however, the population nearly doubled. The area of the administrative county is 422,018 acres. Welsh is the tongue par excellence of Merionethshire. The county returns one member to parliament, and has neither parliamentary nor municipal borough. The probages of Cardigan, Aberdovey, Aberdyfi, Abermaw, Aberystwyth, Abermaw (Abermaw, 2214), Barmouth, Dolgelly (Dolgellau, 2437), Tal-y-llyn (Llwydnę, 3726), and Pwllheli, which is the county, are reckoned out of the county. 

**History and Antiquities.**—This is the only Welsh county retaining in English its primitive British name, latinized into Mercia, a subdivision of Britannia Secunda, and in the English "Mercia's" territory. The present Churc of England, established by the county is remote and discouraged access of his day, and it was not until 1905 that the field of battle in Saxon, Danish or Norman times, nor indeed until close on the period of Welsh loss of independence. There are not many remains, Celtic, Roman or medieval. Caer Drewn, a British fort on the Dee, is near Corwen, where Owen Gwynnedd was posted to repel Henry II. and whither Owen Glendower retired before Henry IV. The numerous cromlechs are chiefly near the coast. The Roman via occidentalis ran through the county from south to north and was joined by a branch of Watling Street at Tomen y Mur (perhaps Henyr Mons) on the Vale of Ewloe, not far from Castell Garmon, Tomen y Mur (detritus of the wall) and Castell Pryor have yielded Roman bricks, tiles, urns and coins. Castell y Bere, an extensive ruin, and once one of Wales's largest castles, has not been inhabited since the time of Edward I. Cymmer Abbey (Y Fanner) near Dolgelly, a Cistercian establishment founded about 1200, and dissolved by Henry VIII., is most perfect at the east end, with lancet windows, and against the south wall there are a few Gothic pillars and arches. The architecture varies from Norman to Perpendicular. Tomen Bala, east of Bala, is probably to be a Roman encampment. It was afterwards occupied by the Welsh, to check the English lords marshes. Moel Offrwn is near Dolgelly. Among the county families may be mentioned that of Hengwrt, since the Hengwrt Welsh MSS. are famous in north Wales and among all Celtic scholars.

**MERISTEM** (Gr. μεριστής, divided or divisible), a botanical term for tissue which has the power of developing new...
forms of tissue, such as the cambium from which new wood is developed.  

MERIVALE, CHARLES (1808-1893), English historian and dean of Ely, the second son of John Herman Merivale and Louisa Heath Drury, daughter of Dr Drury, head master of Harrow, was born on the 8th of March 1808 in St John's College, Cambridge. In 1824 he was offered a lectureship in the Indian civil service, and went for a short time to Harlebury College, where he was distinguished for proficiency in Oriental languages. But he eventually decided against an Indian career, and went up to St John's College, Cambridge, in 1826. Among other distinctions he came out as fourth classic in 1830, and in 1833 was elected fellow of St John's. He was a member of the Apostles' Club, his fellow-members including Tennyson, A. H. Hallam, Monckton Milnes, W. H. Thompson, Trench and James Speckling. He was fond of athletic exercises, had played for Harrow against Eton in 1824, and in 1829 rowed in the first inter-university boat-race, when Oxford won. Having been ordained in 1833, he undertook college and university work in the summer of that year in the capacities of preacher at Whitehall. In 1848 he took the college living of Lawford, near Manningtree, in Essex; he married, in 1850, Judith Mary Sophia, youngest daughter of George Frere. In 1863 he was appointed chaplain to the Speaker of the House of Commons, declined the professorship of modern history at Cambridge in 1869, but in the same year accepted from Mr Gladstone the deanship of Ely, and until his death on the 27th of December 1893 devoted himself to the best interests of the cathedral. He received many honorary academical distinctions. His principal work was A History of Italy in the Middle Ages, which came out between 1850 and 1862; but he wrote several smaller historical works, and published sermons, lectures and Latin verses. Merivale as a historian cannot be compared with Gibbon for virility, but he takes an eminently common-sense and appreciative view. The chief defect of his work, inevitable at the time it was composed, is that, drawing the materials from contemporary memoirs rather than from inscriptions, he relies on literary gossip rather than on numismatics and epigraphy. The dean was an elegant scholar, and his rendering of the Hyperion of Keats into Latin verse (1862) has received high praise.  

See Autobiography of Dean Merivale, with selections from his correspondence, edited by his daughter, Judith A. Merivale (1890); and Family Memorials, by Anna W. Merivale (1884).  

MERIVALE, HERMAN (1806-1874), English civil servant and author, elder brother of the preceding, was born at Dawlish, Devonshire, on the 8th of November 1806. He was educated at Harrow School, and in 1823 entered Oriel College, Oxford. In 1825 he became a scholar of Trinity College and also won the Ireland scholarship, and three years later he was elected fellow of Balliol College. He became a member of the Inner Temple and practised on the western circuit, being made in 1841 recorder of Falmouth, Helston and Penzance. From 1837 to 1842 he was professor of political economy at Oxford. In this capacity he delivered a course of lectures on the British Colonies in which he dealt with questions of emigration, employment of labour and the allotment of public lands. The reputation he secured by these lectures had much to do with his appointment in 1847 as assistant under-secretary for the colonies, and in the next year he became permanent under-secretary. In 1859 he was transferred to the permanent under-secretaryship for India, receiving the distinction of C.B. In 1870 Merivale was made D.C.L. of Oxford. He died on the 8th of February 1874. Besides his Lectures on Colonization and Colonies (1841), he published Historical Studies (1865), and completed the Memoirs of Sir Philip Francis (1867); he wrote the second volume of the Life of Sir Henry Lawrence (1872) in continuation of Sir Herbert Edwardes's work.  

A tribute to his powers as an original thinker by his chief at the Colonial Office, Sir Edward Bulwer-Lytton, is printed with a notice of his career which his brother contributed to the Transactions (1884) of the Devonshire Association.  

Merkara, the capital of the province of Coorg, in Southern India, situated on a plateau about 4000 ft. above the sea. Pop. (1901), 6732. It consists of two quarters: the fort, containing the public offices, the old palace, and the residence of the commissioner; and the native town of Mahadevapet. Here are the headquarters of the Coorg and Mysore Rifles, a body of volunteers chiefly composed of coffee planters.  

Merlin, Antoine Christophe (1762-1833), French revolutionist, called "of Thionville," to distinguish him from his namesake, born at Thionville on the 13th of September 1762, being the son of a procureur in the baillilage of Thionville. After studying theology, he devoted himself to law, and in 1788 was an avocat at the parlement of Metz. In 1790 he was elected municipal officer of Thionville, and was sent by the department of Moselle to the Legislative Assembly. On the 23rd of October 1791 he moved and carried the institution of a committee of surveillance, of which he became a member. It was he who proposed the law sequestrating the Orleans, an emigre's, and the manager of the Baillerie of Thionville at the time of the coup d'etat of the 18th Fructidor (Sept. 4, 1797) demanded the deportation of certain republicans of Thionville. In 1798 he ceased to be a member of the Council of Five Hundred, and was appointed director-general of posts, being sent subsequently to organize the army of Italy. He retired into private life at the proclamation of the consulate, and lived in retirement under the consulate and the empire. He died in Paris on the 14th of September 1833. See J. Reynaud, Vie et correspondance de Merlin de Thionville (Paris, 1860).  

Merlin, Philippe Antoine, Count (1754-1838), French politician and lawyer, known as Merlin "of Douai," was born at Arleux (Nord) on the 30th of October 1754, and was called to the French bar on December 1775. A indefatigable student, he collaborated in the Répertoire de jurisprudence, published by J. N. Guyot, the later editions of which appeared under Merlin's superintendence, and also contributed to other important legal compilations. Elected to the states-general as deputy for Douai, he was one of the chief of those who applied the principles of liberty and equality embodied in the decree of the 4th of August 1789 to actual conditions. On behalf of the committee appointed to deal with feudal rights, he presented to the Convention reports on the seignioral rights which were subject to compensation, on hunting and fishing rights, forestry, and kindred subjects. He carried legislation for the abolition of primogeniture, secured equality of inheritance between relations of the same degree, and between men and women. His numerous reports to the Constituent Assembly were supplemented by popular exposition of current legislation in the Journal de législation. On the dissolution of the Constituent Assembly he became judge of the criminal court at Douai. He was no advocate of violent measures; but, as deputy to the Convention, he voted for the death of Louis XVI., and as a member of the council of legislation he presented to the Convention on the 17th of September 1793 the infamous law permitting the detention of suspects. He was closely allied with his namesake Merlin "of Thionville," and, after the counter-revolution which brought about the fall of Robespierre,
he became president of the Convention and a member of the Committee of Public Safety. His efforts were primarily directed to the prevention of any recurrence of the tyranny exercised by the Jacobin Club, the commune of Paris, and the revolutionary tribunal. He persuaded the Committee of Safety to take upon itself the closing of the Jacobin Club on the ground that it was an administrative rather than a legislative measure. He recommended the readmission of the survivors of the Girondin party to the Convention, and drew up a law limiting the right of insurrection; he had also a considerable share in the foreign policy of the victorious republic. With Cambacérès he had been commissioned in April 1794 to report on the civil and criminal legislation of France, with the result that after eighteen months' work he produced his Rapport et projet de code des délits et des peines (10 Vendémiaire, an. IV.). Merlin's code abolished confiscation, branding and imprisonment for life, and was based chiefly on the penal code drawn up in September 1791. He was made minister of justice (Oct. 30, 1795) under the Directory, and showed excessive rigor against the emigrants. After the coup d'état of the 18th Fructidor he became (Sept. 5, 1797) one of the five directors, and was accused of the various failures of the government. He retired into private life (June 18, 1799), and had no share in the revolution of the 18th Brumaire. Under the consulate he accepted a modest place in the court of cassation, where he soon became procureur-général. Although he had no share in drawing up the Napoleonic code, he did more than any other lawyer to further its interpretation. He became a member of the council of state, count of the empire, and grand officer of the Legion of Honour; but having resumed his functions during the Hundred Days, he was one of those banished on the second restoration. The years of his exile were devoted to his Répertoire de jurisprudence (5th ed., 18 vols., Paris, 1827-1828) and to his Recueil alphabétique des questions de droit (4th ed., 8 vols., Paris, 1827-1828). At the revolution of 1830 he was able to return to France, when he re-entered the Institute of France, of which he had been an original member, being admitted to the Académie des Sciences Morales et Politiques. He died in Paris on the 26th of December 1838.

His son, Antoine François Eugène Merlin (1778-1854), was a well-known general in the French army, and served through most of Napoleon's campaigns.

See M. Miguet, Portraits et notices historiques (1852), vol. i.

**MERLIN** (Welsh, Myrddin), the famous bard of Welsh tradition, and enchanter of Arthurian romance. His history as related in this latter may be summarized as follows. The infernal powers, aghast at the blow to their influence dealt by the Incarnation, determine to counteract it, if possible, by the birth of an Antichrist, the offspring of a woman and a demoniac with castes of his name, as subject of the diabolic experiment, their property is destroyed, one after the other perishes miserably, till one daughter, who has placed herself under the special protection of the Church, is left alone. The demon takes advantage of an unguarded moment of despair, and Merlin is engendered. Thanks, however, to the prompt action of the mother's confessor, Blaye, in at once baptizing the child of this abnormal birth, the mother truly protesting that she has had intercourse with no man, Merlin is claimed for Christianity, but remains dowered with demonic powers of insight and prophecy. An infant in arms, he saves his mother's life and confounds her accusers by his knowledge of their family secrets. Meanwhile Vortigern, king of the Britons, is in despair at the failure of his efforts to build a tower in a certain spot; however high it may be reared in a day, it falls again during the night. He consults his diviners, who tell him that the foundations must be watered with the blood of a child who has never had a father; the king accordingly sends messengers through the land in search of such a prodicty. They come to the city where Merlin and his mother dwell at the moment when the boy is cast out from the companionship of the other lads on the ground that he has had no father. The messengers take him to the king, and on the way he astonishes them by certain prophecies which are fulfilled to their knowledge. Arrived in Vortigern's presence, he at once announces that he is aware alike of (the fate destined for him and of the reason, hidden from the magicians, of the fall of the tower. It is built over a lake, and beneath the waters of the lake in a subterranean cavern lie two dragons, a white and a red; when they turn over the tower falls. The lake is drained, the correctness of the statement proved, and Merlin's position as court prophet assured. Henceforward he acts as adviser to Vortigern's successors, the princes Ambrosius and Uther (subsequently Uther-Pendragon). As a monument to the Britons fallen on Salisbury Plain he brings from Ireland, by magic means, the stones now forming Stonehenge. He aids Uther in his passion for Yguerne, wife to the duke of Cornwall, by Merlin's spells Uther assumes the form of the husband, and on the night of the duke's death Arthur is engendered. At his birth the child is committed to Merlin's care, and by him given to Antor, who brings him up as his own son. On Arthur's successful achievement of the test of the sword in the "perron," Merlin reveals the truth of his parentage and the fact that he is by hereditary right, as well as by divine selection, king of the Britons. During the earlier part of Arthur's reign Merlin acts as counsellor; then he disappears mysteriously from the scene. According to one account he is betrayed by a maiden, Nimue or Ninniane (a king's daughter, or a water-fairy, both figure in different versions), of whom he is enamoured, and who having beguiled him from a knowledge of magic spells casts him in a dark cavern, where he lives in a rocky tomb. This version, with the great cry, or Brait, which the magician uttered before his death, appears to have been the most popular. Another represents his prison as one of air; he is invisible to all, but can see and hear, and occasionally speak to passers by; thus he holds converse with Gawain. In the prose Perciwal he retires voluntarily to an "Esplumeor" erected by himself, and is seen no more of man.

The curious personality of Merlin is now generally recognized as being very largely due to the prolific invention of Geoffrey of Monmouth. Nennius, upon whose Historia Brittonum enlarged and "improved," the story of Vortigern and the tower, but the boy's name is Ambrosius. Geoffrey calls him Merlin-Ambrosius, a clear proof that he was adapting Nennius's story. He represents the sage in his rôle of court diviner, his "Prophéctes" being incorporated in later manuscripts of the Historia. Subsequently Geoffrey enlarged on the theme, composing a Vita Merlini in which we find the magician in the rôle of a "possessed" wood-ahoUder, fleeing the haunts of men, and consorting with beasts. This gave rise to the idea that there had originally been two Merlins, Merlin-Ambrosius and Merlin of Wydevester, a view also discredited by the leading scholars. The Viz was so successful that Geoffrey obtained as reward the bishopric of St Asaph.

Welsh vernacular literature has preserved a small but interesting group of poems, strongly national and patriotic in character, which are attributed to Merlin (Myrddin).

A few years after Geoffrey's death Merlin's adventures were amplified into a romance, the first draft of which is attributed to Robert de Boron, and which eventually took the form of a lengthy introduction to the prose Lancelot and cyclic recreation of the Arthurian legend.

The romantic, as distinguished from legendary or historical Merlin, exists in the following forms: (a) a fragmentary poem preserved in a unique manuscript of the Bibl. nat. (this gives no more than the introduction to the story); (b) a prose rendering of the above, of which a fair number of copies exist, generally in a Latin original poem with a version of the early history of the Grail, known as Joseph of Arimathea, and in two cases followed by a Perciwal and Mort Artas, thus forming a small cycle; (c) the Ovus, a very late and very primitive story of Merlin, of which numerous copies exist (see Dr Sommer's edition); and (d) (e) two continuations to the above, each represented by a single manuscript—(d) the "Huch Merlin" which was utilized by Malory for his translation, and (e) a very curious manuscript, 337, Bibl. nat. (fonds Français), which Paulin Paris calls the Livre Artas, containing much matter not found elsewhere.

M. La Villerméquart's "critical study" (Myrddin, l'enchanteur..."
MERLON—MERMAIDS 171

Merlin, 1861) cannot be regarded as much more trustworthy than Geoffrey himself. The story of the tower, and the Boy without a Father, has been critically examined by Dr Gaster, in a paper read at the Society for the Promotion of Folk-lore (vol. vii.). Dr Gaster cites numerous Oriental parallels to the tale, and sees in it the germ of the whole Merlin legend. Alfred Nutt (Revue Celtique, vol. xxviii.) has since shown that Arthur can be derived from a Danish Irish, and of unknown parentage, and it seems more probable that the Boy without a Father theme was generally associated with the Celtic magic of Merlin, than that it was merely an adventurous personage and those assigned by Geoffrey to Merlin in the Vita; the text given by Mr Ward states that some people identified Lailoken with Merlin. The author of the recent examination of the sources of the Vita Merlini (Annales de Bretagne, vol. xv.), has pointed out the more original character of the "Lailoken" fragments, and decides that Geoffrey knew the Scottish tradition and utilized it for his Vita. He also comes to the conclusion that the Welsh Merlin poems, with the possible exception of the Dialogue between Merlin and Taliesin, are posterior to, and inspired by, Geoffrey's work. So far the researches of scholars appear to point to the result that the legend of Merlin, as we know it, is of complex growth, combined from traditions of independent and widely differing origin. Most probably there is a certain substratum of tradition which may have been derived from a bard; there may have been a bard, and soothsayer of that name, and it is by no means improbable that curious stories were told of his origin. It is worth noting that Layamon, whose translation of Wace's Brut is of the thirteenth century, says that "In the beginning of the world..." The statement of the text, gives a much more favourable form of the "Birth" story; the father is a glorious and supernatural being, who appears to the mother in her dreams. Layamon lived on the Welsh border, and the possibility of his variants being drawn from genuine British tradition is generally recognized. The poem relating a dialogue between Merlin and his brother bard, Taliesin, may also derive from genuine tradition. Further than this we can hardly venture to go; the probability is that anything more told of the character and career of Merlin rests upon the imaginative powers and faculty of combination of Geoffrey of Monmouth.

MERLON, in architecture, the solid part of an emblattet parapet between the embrasures, sometimes pierced by loopholes. The word is French, adapted from Ital. merlone, possibly a shortened form of morgola, connected with Lat. morga, power, force or trick. From a diminutive merulaus, from muros (moerus), a wall.

MERMAIDS and MERMEN, in the folk-lore of England and Scotland, a class of semi-human beings who have their dwelling in the sea, but are capable of living on land and of entering into social relations with men and women.1 They are easily identified, at least in some of their most important aspects, with the Old German Merimini or Meerfrau, the Icelandic Hafgufa, Margyrg, and Marnennil (mod. Marbednill), the Danish Hafmand or Maremid, the Irish Merrow or Merreach, the Marie-Morgan of Britain and the Morfowryn of Wales, and they have various points of resemblance to the vodyany or water-sprite and the ruskula or stream-fairy of Russian mythology. The typical mermaid has the head and body of a woman, usually of exceeding loveliness, but below the waist is fashioned like a fish with scales and fins. Her hair is long and beautiful, and she is often represented, like the Russian ruskula, as combing it with one hand while in the other she holds a looking-glass. For a time at least a mermaid may become to all appearance an ordinary human being; and an Irish legend("The Overflowing of Lough Neagh and Lissan,

1 From Gaiman’s "The Mermaid," in Joyce's Old Celtic Romances represents the temporary transformation of a human being into a mermaid.

The mermaid legends of all countries may be grouped as follows. (a) A mermaid or merman either voluntarily or under compelling reveal things that are about to happen. Thus the two mermaids (merciwip) Headbrec and Siglent, in the Nibelungenlied, disclose his future course to the hero Hagen, who, having got possession of their garments, which they had left on the shore, compels them to pay ransom in this way. According to Resien, a mermaid appeared to a peasant of Sansieø, for told the birth of a prince, and moralized on "the evils of intemperance, &c. (Kong Fredericks den andens Krönike, Copenhagen, 1680, p. 302). (b) A mermaid imparts supernatural powers to a human being. Thus in the beautiful story of "The Old Man of Cury" (in Hunt's Popular Romances of the West of England, 1871) the old man, instead of silver and gold, obtains the power of doing good to his neighbours by breaking the spells of witchcraft, chasing away diseases, and discovering thieves. (c) A mermaid has some one under her protection, and for wrong done to her ward exacts a terrible penalty. One of the best and most detailed examples of this class is the story of the "Mermaid's Vengeance" in Hunt's book already quoted. (d) A mermaid falls in love with a human being, lives with him as his lawful wife for a time, and then, some compact being unwittingly or intentionally broken by him, departs to her true home in the sea. Here, if its mermaid form be accepted, the typical legend is undoubtedly that of Mélusine (q.v.), which, being made the subject of a romance by Jean d’Arras, became one of the most popular folk-books of Europe, appearing in Spanish, German, Dutch and Bohemian versions. Thus in the original version in the French "Pentonville," the English mermaid Mermenine, is made a mermaid, and entices him to go to live with her below the sea; or a merman wins the affection or captures the person of an earth-born maiden. This form of legend is very common, and has naturally been a favourite with poets. Macphall of Colonysa successfully rejects the allusions of the mermaid of Corrievekin, and comes back after long years of trial to the maid of Colonysa.\nThe Danish ballads are especially full of the theme; as "Agnete and the Merman," an antecedent of Matthew Arnold's "Forsaken Merman"; the "Deceitful Merman, or Marstig's Daughter," and the finely detailed story of Rosmer Hafmand (No. 90 in Grimm). In relation to man the mermaid is usually of evil issue if not of evil intent. She has generally to be bribed or compelled to utter her prophecy or bestow her gifts, and whether as wife or paramour she brings disaster in her train. The fish-tail, which in popular fancy forms the characteristic feature of the mermaid, is really of secondary importance; for the true Teutonic mermaid—probably a remnant of the great cult of the Vanir—had no fish-tail;2 and this symbolic appendage occurs in the mythologies of so many countries as to afford no clue to its place of origin. The Tritons, and, in the later representations, the Sirens of classical antiquity, the Phoenician Daegar, and the Chaldæan Oannes are all well-known examples; the Ottawas and other American Indians have their man-fish and woman-fish (Jones, Traditions of the North American Indians, 1836); and the Chinese tell stories not unlike our own about the sea-women of their southern seas (Dennis, Folklore of China, 1875).

Quasi-historical instances of the appearance or capture of mermaids are common enough,3 and serve, with the frequent use of the figure on signboards and coats of arms, to show how thoroughly the myth had taken hold of the popular imagination.4

1 See Leyden's "The Mermaid," in Sir Walter Scott's Border Minstrelsy.

2 From the word "mermaid," New Finds in Shetland and Welsh Folk-Lore, in Gentleman's Magazine (1882).

3 Compare the strange account of the quasi-human creatures found in the Nile given by Theophractus, Historiae, viii. 16, pp. 290-303. of Beikker's edition, and generalized on the use of the word in various parts of England (i.e. as a noun), and used by those of the Ellis, Byron, Phené, Skeffington and other families.

4 The English mermaid represents the creatures with a single tail, the French and German heralds frequently with a double one.

1 See Rhys’s "Welsh Fairy Tales," in Y Cymmrodor (1881, 1882).
A mermaid captured at Bangor, on the shore of Belfast Lough, in the 6th century, was not only baptized, but admitted into some of the choirs of the church as a new and remarkable figure (Notes and Queries, Oct. 21, 1882); and Stowe (Annales, under date 1187) relates how a man-fish was kept for six months and more in the castle of Orford in Suffolk. As showing how legendary material may gather round a simple fact, the oft-told story of the mermaid of Edam is particularly interesting. The oldest authority, Joh. Gerbrandus a Leydis, a Carmelit monk (d. 1304), tells (Annales, &c., Frankfurt, 1620) how in 1493 a wild woman came through a breach in the dike into Purmerlake, and, being found by some Edam milkmaids, was ultimately taken to Haarlem and kept there for three months. Nobody could understand her, but she learned to spin, and was wont to adore the cross. Ocke Scharlenis (Chronik van Friesland, Leeuward, 1597) reasons that she was not a fish because she could spin, and she was not a woman because she could live in the sea; and thus in due course she got fairly established as a genuine mermaid. Vossenaar, who has carefully investigated the matter, enumerates forty writers who have repeated the story, and shows that the older ones speak only of a woman (see Besch. van de zoogen. Meerm. van der stad Haarlem); in Verh. van de Holl. Maatsch. van k. w. Wet., part 23, No. 1786).

The best account of the mermaid-myth is in Baring-Gould’s Myths of the Middle Ages. See also, besides works already mentioned, Pontoppidan, who in his logically credulous way collects much matter to prove the existence of mermaids; Multon, who also (Hague, 1755); Grimm, Deutsche Mythologie, i. 404; and Altdorfer, Heldenerlebnis (1811); Waldron’s Description and Train’s Hist. and Stat., Act. of the Isle of Man; Folk-Lore Society’s Record, vol. ii.; Napoleon, Hist. and Trouv. Tales connected with the South of Scotland; Sibulot, Traditions de la haute Bretagne (1882), and Contes des marins (1882).

MEROBAUDES, Flavius (5th century A.D.), Latin rhetorician and poet, probably a native of Baetica in Spain. He was the official laureate of Valentinian III. and Aëtius. Till the beginning of the 19th century he was known only from the notice of him in the Chronicle (year 443) of his contemporary Isidius, where he is praised as a poet and orator, and mention is made of statues set up in his honour. In 1813 the base of a statue was discovered at Rome, with a long inscription belonging to the year 435 (C.I.L. vi. 1724) upon Flavius Merobaudes, celebrating his merits as warrior and poet. Ten years later, Niebuhr discovered some Latin verses on a palimpsest in the monastery of St Gall, the authorship of which was traced to Merobaudes, owing to the great similarity of the language in the prose preface to that of the inscription. Formerly the only poem of Merobaudes was a short poem (39 hexameters) De Christo, attributed to him by Monumentum Claudian by another; but Ebert is inclined to dispute the claim of Merobaudes to be considered either the author of the De Christo or a Christian.

The "Panegyric" and minor poems have been edited by B. G. Niebuhr (1824); by J. Beker in the Bonn Corpus scriptorum hist. Byz. (1856); the "De Christo" in T. Birt’s Claudian (1802), where the authorship of Merobaudes is upheld; see also A. Ebert, Geschichte der Literatur des Mittelalters im Abendlande (1889).

MEREO, the general name (as Island of Meroe) for the region bounded on three sides by the Nile (from Atbara to Khartum), the Atbara, and the Blue Nile; and the special name of an ancient city on the east bank of the Nile, 877 m. from Wadi Halfa by river, and 554 by the route across the desert, near the site of which is a group of villages called Bakarawiya. The site of the city is marked by over two hundred pyramids in three groups, of which many are in ruinous condition. After the conquest of the desert by the British army, among whom F. Caillaud (Voyage à Meroé, Paris, 1826-1828) observes special mention, some excavations were executed on a small scale in 1834 by G. Ferlini (Censo sugli scavi operati nella Nubia e catalogo degli oggetti ritrovati, Bologna, 1837), who discovered (or professed to discover) various antiquities, chiefly in the form of jewelry, now in the museums of Berlin and Munich. The ruins were examined in 1834 by C. R. Lepsius, who brought many plans, sketches and copies, besides actual antiquities, to Berlin. Further excavations were carried on by E. W. Budge in the years 1902 and 1903, the results of which are recorded in his work, The Egyptian Sudan: its History and Monuments (London, 1897). Troops were furnished by Sir Reginald Wingate, governor of the Sudan, who made paths to and between the pyramids, and sank shafts, &c. It was found that the pyramids were regularly built over sepulchral chambers, containing the remains of bodies either burned or buried without being mummified. The most interesting objects found were the relics on the chapel walls, already described by Lepsius, and containing the names with representations of queens and some kings, with various deities. The graves were marked by manufactory vessels with inscriptions in the Meriotic language, and some vessels of iron and earthenware. The best of the relics were taken down stone by stone in 1905, and set up partly in the British Museum and partly in the museum at Khartum. In 1910, in consequence of a report by Professor Sayce, excavations were commenced in the mounds of the town and the necropolis by J. Garstang on behalf of the university of Liverpool, and the ruins of a palace and several temples were discovered, built by the Meriotic kings.

(See further ETHIOPIA.)

MEROPE was probably also an alternative name for the city of Napata, the ancient capital of Ethiopia, built at the foot of Jebel Barkal. The site of Napata is indicated by the villages of Sanam Abu Dom on the left bank of the Nile and Old Merawi on the right bank of the river, New Merawi, 1 m. east of Sanam Abu Dom and on the same side of the river, was founded by the Sudan government in 1905 and made the capital of the mudirija of Dongola.

(D. S. M.*)

MEROVINGIANS, the name given to the first dynasty which reigned over the kingdom of the Franks. The name is taken from Merovech, one of the first kings of the Salian Franks, who succeeded to Clodio in the middle of the 5th century, and soon became the centre of many legends. The chronicer known as Fredigerius Scholasticus relates that a queen was once sitting by the seashore, when a monster came out of the sea, and by this monster she subsequently became the mother of Merovech, but this myth is due to an attempt to explain the hero’s name, which means "the sea-born." At the great battle of Mauriac (the Catalanian fields) in which Aetius checked the invasion of the Huns (451), there were present in the Roman army a number of Frankish foederati, and a later document, the Vita Lupi, states that Merovech (Merovaeus) was their leader. Merovech was the father of Childeric I. (457-481), and grandfather of Clovis (481-511), under whom the Salian Franks conquered the whole of Gaul, except the kingdom of Burgundy, Provence and Septimania. The sons of Clovis divided the dominions of their father between them, made themselves masters of Burgundy (532), and in addition received Provence from the Ostrogoths (537); Septimania was not taken from the Arabs till the time of Pippin, the founder of the Carolingian dynasty. From the death of Clovis to that of Dagobert (639), the Merovingian kings displayed considerable energy, both in their foreign wars and in the numerous wars against one another in which they found an outlet for their barbarian instincts. After 639, however, the race began to decline, one after another the kings succeeded to the throne,
MERRILL—MERSEBURG

but none of them reached more than the age of twenty or twenty-five; this was the age of the "rois fantaisistes." Henceforth the real sovereign was the mayor of the palace. The mayors of the palace belonging to the Carolingian family were able to keep the throne vacant for long periods of time, and finally, in 731 the mayor Pippin, with the consent of the pope Zacharias, succeeded Childeric III. to the throne at St. Dionysius, and set up his young son Thierry in that of St. Wandrille. The Merovingian race thus came to an end in the cloister.

MERRILL, a city and the county-seat of Lincoln county, Wisconsin, 185 m. N.W. of Milwaukee, on both sides of the Wisconsin river. Pop. (1910 census), 8680. It is served by the Chicago, Milwaukee & St. Paul railroad. The city is situated about 1720 ft. above the sea and has an invigorating climate. Brook trout and various kinds of game, including deer, abound in the vicinity. Grandfather Falls and the Delles of the Prairie river are picturesque places near the city, and furnish good water-power. The principal public building is the Lincoln county court house, and the city contains the T. B. Scott free library, a fine high-school, and the Ravn hospital, a private institution. Riverside Park is maintained by a corporation, and a park along the Prairie river is owned and maintained by the city. Merrill is an important hardwood lumber market, and its principal industry is the manufacture of lumber and lumber products. The manufacture of paper and paper pulp and of lathes is also important. In 1905 the factory products were valued at $3,260,638. There are granite quarries and brickyards in the vicinity. Merrill was settled in 1850, incorporated as a village in 1880, and chartered as a city in 1883.

MERRIMAC, a river in the north-eastern part of the United States, having its sources in the White Mountains of New Hampshire, and flowing south into Massachusetts, and thence east and north-east into the Atlantic Ocean. With its largest branch it has an extreme length of about 183 m. The Merrimack proper is formed at Franklin, New Hampshire, by the junction of the Pemigewasset and Winnipesaukee rivers. The former is the larger branch and rises in the White Mountains in Grafton county. The water of the outlet of Lake Winnipesaukee, the main head of the valley of the Merrimack was formed before the glacial period and was filled with drift as the ice retreated; subsequently the high flood plain thus formed has been trenched, terraces have been formed, and at different places, where the new channel did not conform to the pre-glacial channel, the river has come upon buried ledges, relatively much more resistant than the drift below, and waterfalls have thus resulted. The river falls 269 ft. in a distance of 110 m. from Franklin to its mouth. The greater part of the total fall is at six points, and at each of four of these is a city which owes its importance in great measure to the water-power thus provided, Lowell and Lawrence in Massachusetts, and Manchester and Concord in New Hampshire; at Lowell there is a fall of 30 ft. (Pawtucket Falls), and at Manchester there is a fall of 55 ft. (Amoskeag Falls). The region drained by the river is 4833 sq. m. in extent, and contains a number of lakes, which together with some artificial reservoirs serve as a storage system. On the navigable portion of the river, which extends 137 m., above its mouth, are the cities of Newburyport and Haverhill, at the head of navigation. In 1890-1908 the Federal government dredged a channel from Newburyport to Haverhill (14.5 m.) 7 ft. deep and 150 ft. wide at mean low water; vessels having a draft of 12-5 ft. could then pass over the outer bar of Newburyport.

MERRIMAN, HENRY SETON (d. 1903), the pen-name of Hugh Stowell Scott, English novelist. He was a member of the firm of Henry Scott & Sons, and was for some years an underwriter at Lloyd's. His literary career began in 1889 with The Phantom Future, and he made his first decided hit with his Russian story, The Sowers (1896), which was followed by many other well-written novels remarkable for excellence of plot and literary handling. The author was an enthusiastic traveller, many of his journeys being undertaken with his friend Stanley Weyman. He was about forty when he died at Melton, near Ipswich, on the 19th of November 1903. Among his most successful books were Roden's Corner (1898); The Isle of Unrest (1900); In Kedar's Tent (1897); The Velvet Glove (1891); The Vulture (1902); Barlasch of the Guard (1903); and The Last Hope (1904).

MERRITT, WESLEY (1836- ), American soldier, was born in New York City on the 16th of June 1836. He graduated at West Point in 1860, and was assigned to the cavalry service. He served in Utah (1861) and in the defences of Washington (1861-62); learnt the field duties of his arm as aide (1862) to General Philip St George Cooke, who then commanded the cavalry of the Army of the Potomac; became brigadier-general, United States Volunteers, in June 1863; and in September 1863 was placed in command of a brigade of regular cavalry in the Army of the Potomac. He won great distinction in the Virginian campaigns of 1864-65 and in Sheridan's Valley campaign, being brevetted major-general of volunteers for his conduct at Winchester and Fisher's Hill, and brigadier-general of the regular army for his services at Five Forks. In the final campaign about Richmond he did such good service in command of a cavalry division that he was brevetted major-general in the regular army and was promoted major-general of volunteers. With two other Federal commissioners he was on the Confederate commissioners for the surrender of the Army of Northern Virginia. He was mustered out of the Volunteer Service in February 1866, and in July became lieutenant-colonel of the 4th cavalry in the regular army, being promoted gradually to major-general (1895). He served in the Big Horn and Yellowstone Indian campaigns (1876) and in the expedition to relieve the command of Major Thornburgh, who was killed in 1879 by the Utes; was superintendent at West Point (1882-87); and commanded the military department of Missouri in 1887-95, and that of the Atlantic in 1897-98. He was assigned in May 1898 to the command of the United States forces in the Philippines, who accompanied Dewey's victory; stormed Manila on the 13th of August; and was military governor of the islands until the 30th of August, when he left Manila for Paris to join the peace commission. From 1890 until his retirement from active service in June 1900 he commanded the Department of the East.

MERSEBURG, a town of Germany, in the Prussian province of Saxony, on the river Saale, 10 m. by rail S. of Halle and 75 m. W. of Leipzig. Pop. (1905), 20,024. It consists of a quaint and irregularly built old town, a new quarter, and two extensive suburbs, Altenburg and Neumarkt. The cathedral, which was restored in 1861-1866, has a choir, a crypt and two towers of the 17th, a transept of the 13th and a late Gothic nave of the 16th century. Among its numerous monuments is one to Rudolph of Swabia, the rival of the emperor Henry IV. It contains

1The name is an Indian word said to mean 'swift water.' In popular usage the spelling 'Merrimack' is used at places along the river above Haverhill.
a great organ dating from the 17th century. Near the cathedral is the Gothic palace, formerly the residence of the bishops of Merseburg, and now used as public offices. The town hall and the Stallhaus, where the meetings of the provincial estates were held, are also noteworthy buildings. The industries include the manufacture of machinery, paper and celluloid, and tanning and brewing.

Merseburg is one of the oldest towns in Germany. From 962 until the Reformation, it was the seat of a bishop, and in addition to being for a time the residence of the margraves of Meissen, it was a favourite residence of the German kings during the 10th, 11th and 12th centuries. Fifteen diets were held here during the middle ages, when its fairs enjoyed the importance which was afterwards transferred to those of Leipzig. The town suffered severely during the Peasants' War and also during the 'Thirty Years' War. From 1657 to 1738 it was the residence of the dukes of Saxe-Merseburg.

See E. Hoffmann, Historische Nachrichten aus Alt-Merseburg (Merseburg, 1903).

MERSEN (MERSSSEN), Treaty of, a treaty concluded on the 8th of August 879 at Merse, in Holland, between Charles the Bald and his half-brother, Louis the German, by which the kingdom of his nephew Lothair II. (d. 869) was divided between them. Charles received a portion of the kingdom of Lothair afterwards called Lorraine, extending from the mouths of the Rhine to Toul, together with the town of Besançon, the Lyonnais, the Viennais, the Vivarais, and the Uzège, i.e. the lands acquired by Lothair II. in 863 at the death of his brother Charles of Provence; while Louis had the cities of Chalon, Lyons, the prefectures of Savoy, and the Varais, i.e. the greater part of the diocese of Besançon.

The boundary between the two realms was marked approximately by the valleys of the Meuse and Moselle and by the Jura. Great importance has been attached to the determination of this frontier by some historians, who consider that it coincided with the dividing line between the Teutonic and Romance races and languages; but nothing is known of the bases upon which the negotiations were effected, and the situation created by this treaty came to an end in 879.

MERSENE, MARIN (1588-1648), French philosopher and mathematician, was born of peasant parents near Oizé (Sarthe) on the 8th of September 1588, and died in Paris on the 1st of September 1648. He was educated at the Jesuit College of La Flèche, where he was a fellow-pupil and friend of Descartes. In 1611 he joined the Minin Friars, and devoted himself to philosophic teaching in various convent schools. He settled eventually in Paris in 1620 at the convent of L'Annonciade. For the next four years he devoted himself entirely to philosophic and theological writing, and published Quaestiones celebrissimae in Generis (1623); L'Impétitude des déistes (1624); La Vérité des sciences (1624). These works are characterized by wide scholarship and the narrowest theological orthodoxy. His greatest service to philosophy was his enthusiastic defence of Descartes, whose agent he was in Paris and whom he visited in exile in Holland. He submitted to various eminent Parisian thinkers a manuscript copy of the Méditations, and defended its orthodoxy against numerous clerical critics. In later life, he gave up speculative thought and turned to scientific research, especially in mathematics, physics and astronomy. Of his works in this connexion the best known is L'Harmonie universelle (1636), dealing with the structure of music and musical instruments.

Among his other works are: Euclides elementorum libri, 8c. (Paris, 1625); Universae geometriae synopsis (1644); Les Méchaniques de Galilée (Paris, 1634); Questions innues ou récréations des savans (1634); Questions théologiques, physiques, &c. (1634); Nouvelles découvertes de Galilée (1635); Logistica physicae mechanicae (1646). See Baillet, Vie de Descartes (1691); Poté, Éloge de Mersenne (1816).

MERSEY, a river in the north-west of England. It is formed by the junction of the Goyt and the Etherow a short distance below Marple in Cheshire on the first-named stream. The Goyt rises in the neighbourhood of Axe Edge, south-west of Buxton, and the Etherow in the uplands between Penistone and Glossop, watering the narrow Longdendale in which are several reservoirs for the Manchester water supply. The Mersey thus drains a large part of the Peak district of Derbyshire and of the southern portion of the Pennine system. The general direction from Marple is westerly. At Stockport the river Tame joins from the north, rising in the moors to the north-east of Oldham, and the Mersey soon afterwards debouches upon the low plain to the west of Manchester, which lies on its northern tributary, the Medlock. The main river, passing Warrington, begins to expand into an estuary before reaching Runcorn and Widnes, which face each other across it. The estuary, widening suddenly at the junction of the Weaver from the south-east, 25 m. below Runcorn, is 3 m. wide off Ellesmere Port, but narrows to less than ½ m. at Liverpool, and hardly extends a mile at the mouth in the Irish Sea. The fall of the Mersey is about 1600 ft. in all and about 300 ft. from Marple; its length, including the Goyt, is 70 m. exclusive of lesser windings, and it drains an area of 1596 sq. m. The estuary is one of the most important commercial waterways in the world. (See Liverpool and Birkenhead.) The Manchester Ship Canal (q.v.) joins the estuary through Eastham Locks, skirts its southern shore up to Runcorn, and crosses the river several times. From the name of the river was taken the title of Lord Mersey in 1910 by Sir John Bigham (b. 1840), on his elevation to the peerage after serving as a judge of the high court from 1897 to 1909 and president of the divorce court 1909-1910.

MERSINA, a town on the south-eastern coast of Asia Minor, and capital of a sanjak in the vilayet of Adana. Pop. about 15,000 including many Christians. Ardealin, as it is called, was a Greek town of some importance, and Seat of a Greek bishopric. It passed into the hands of the Turks in 1463, and was from 1570 to 1822 the seat of a Patriarch of the Armenians of the old Catholicosate of Cilicia. Its existence as a port began with the sitting up of the harbour of Tarsus and Pompeiopolis, east and west, in the early middle ages; but it did not rise to importance till the Egyptian occupation of Cilicia (1832). It is now the busiest port on the south coast, being the terminus of the railway from Tarsus and Adana, by which (but still more by road) the trade of the rich “Aleian” plain comes down. It is served by most of the Levantine steamship companies, and is the best point of departure for visitors desiring to see Tarsus, the Cilician remains, and the finest scenery of the East Taurus. There is, however, no enclosed harbour, but only a good jetty. The making of a breakwater has long been under consideration. The anchorage in the roadstead is good, but the bay shoals for a long way out, and is exposed to swell from south-west and south. Mersina is an American mission centre, and the seat of a British vice-consul. Like all lowland Cilicia, it has a notoriously bad summer climate, and all inhabitants, who can do so, migrate to stations on the lower slopes of Taurus.

(D. G. H.)

MERTHYR TYDFIL, or Merthyr Tydfil, a municipal, county and parliamentary borough, and market-town of Glamorganshire, south Wales, situated in a bleak and hilly region on the river Taff, on the Glamorganshire Canal, and the Brecon and Merthyr, Great Western, North Western, Taff Vale and Rhymney railways, 25 m. N.N.W. of Cardiff, 30 E.N.E. of Swansea, and 176 from London. Pop. (1901), 69,228. The town is said to have derived its name from the martyrdom of St Tydfil, daughter of Brychan, who was put to death by Saxons in the 5th century. It is for the most part irregularly and was formerly subject to severe epidemics due to defective sanitation; but it now possesses a supply of the purest water from the Lessons. Taff in the lower reaches of the Breconshire Beacons. The town owes its early industrial prosperity to the abundant ironstone and coal of the district, and it thus became at an early date the chief seat of the iron industry in Wales. Four great ironworks were established here between 1759 and 1782. With the earliest, that of Dowlais, the Guest family were associated, first as partners and later as sole owners from 1782 to 1901 when the works were disposed to the company of Guest, Keen and Nettlefold. In 1765, Cyfarthfa was started by Anthony Bacon, and when firmly established, sold in 1794 to Richard Crawshay by whose descendants the works were-
MERULA—MERV

175

carried on till the owners formed themselves in 1806 into a limited company (Crawshay Brothers Cyfarthfa Limited), the controlling interest in which has since been acquired by the Dowlais Company. The Plymouth works, started soon after Cyfarthfa, by Wilkinson and Guest, passed later into the hands of Anthony Hill from whose descendants they were purchased in 1863. They were closed down in 1889, but the collieries belonging to them continue to be worked on a large scale, yielding over 20,000 tons of coal a day. The fourth great ironworks, those of Pen-y-darren, were carried on from 1782 to 1859. It was at Dowlais (in 1856) that Bessemer steel was first rolled into rails, but the use of puddled iron was not wholly abandoned at the works till 1882. It has now eighteen blast furnaces, and extensive collieries are also worked by the company, and large branch works were opened on the sea-board at Cardiff in 1891.

Cyfarthfa was converted into steel works in 1883. The iron ore used is mainly imported from Spain. Merthyr Vale is almost entirely dependent on coal-mining and has one of the largest collieries in south Wales (Nixon's Navigation). The population of this district more than quintupled between 1861 and 1891.

From 1850 the government of the town was vested in a local board of health which in 1894 became an urban district council; by charter granted on the 5th of June 1905, it was vested in a corporation consisting of a mayor, 8 aldermen and 24 councillors. It was made a county borough from the 1st of April 1908. It comprises about 17,750 acres, is divided into eight wards and besides the older town, it includes Penydarren (1 m. N.E.), Dowlais (2 m. N.E.), Plymouth (1 m. S.) and Merthyr Tydfil in conjunction with Aberdare and the Mountain Ash, has had a stipendiary magistrate since 1829. The parliamentary borough which was created and given one member in 1832 and a second in 1867, includes the parish of Aberdare and parts of the parishes of Llanwonno, Merthyr Tydfil and Vainor (Brecon).

There is an electric tramway (completed in 1901) from the town to Cefn and Dowlais. In 1901 about 50% of the population above three years of age spoke both Welsh and English, 71% spoke Welsh only, and the remainder English only. The ancient parish of Merthyr Tydfil has been divided into five ecclesiastical parishes (Merthyr, Cyfarthfa, Dowlais, Pentrebach, and Penydarren) and part of another parish (Treharris). These six parishes form the rural deanery of Merthyr in the archdeaconry and diocese of Llandaff, and in 1906 had nine churches and fifteen mission rooms. An inscribed stone (Arthur) has been built into the east wall of the parish church; and two other inscribed stones removed from Abercarn Farm in the greater Taff valley now lie in the parish churchyard. The old structure of the parish church has been entirely removed except the base of the tower. There is a Roman Catholic church in Penydarren Park and another at Dowlais. The Nonconformists of which the chief denominations are the Baptists, Congregationalists and Methodists—Wesleyan and Calvinistic—had in 1906 82 chapels, 49 of which were used for Welsh services and 33 for English.

The public buildings include, besides the churches, a town hall and law courts (1868), drill hall (1866), library, market house, a county intermediate school, general hospital built in 1857 and enlarged in 1897, and an isolation fever hospital, a theatre (1894) and a fountain presented by Sir W. T. Lewis as a memorial to the pioneers of the town's industry. At Dowlais there are mineral works (1900) and a free library which have been provided by the owners of the Dowlais Works, Oddfellows' hall (1878), and a fever hospital (1866). At Thomas Town there is a recreation ground of 16 acres, formed in 1902. In 1908 the corporation purchased Cyfarthfa Castle (formerly the residence of the Crawshay family) with a park of 62 acres including a lake of 6 acres.

The Roman road from Cardiff and Gelliger to Brecon passed through Merthyr and the remains of the fort were discovered in Penydarren park in 1902. Three miles to the north of Merthyr, on a limestone rock about 470 ft. above the lesser (eastern) Taff are the ruins of Morfais Castle, built about 1256 by Gilbert de Clare on the northern limits of his lordship of Glamorgan, its erection causing a serious feud between him and de Bohun, earl of Hereford, who claimed its site as part of the lordship of Breconwick.

(D. L. T.)

MERULA, GEORGIE (the Latinate name of GiorGio MIRLAND; c. 1430-1404), Italian humanist and classical scholar, was born at Alessandria in Piedmont. The greater part of his life was spent at Venice and Milan, where he held a professorship and continued to teach until his death. To Merula we are indebted for the editio princeps of Plautus (1472), of the Scriptores reris sanctae, Cato, Varro, Columella, Palladius (1472) and possibly of Martial (1471). He also published commentaries on portions of Cicero (especially on De finibus), and Ausonius, Juvenal, Curtius Rufus, and other classical authors. He wrote also Belium sodromeni (1474), on account of the siege of Scodra (Scutari) by the Turks, and Antiqulutes vicecomitum, the history of the Visconti, dukes of Milan, down to the death of Matteo the Great (1392). He violently attacked Politian (Poliziano), whose Miscellanea (a collection of notes on classical authors) were declared by Merula to be either plagiarized from his own writings or, when original, to be entirely incorrect.

See monograph by F. Gabotto and Badini-Gonfalonieri (1894) with covering bibliography; for Politian see—Meiners Lebensbeschreibungen der berühmten Männer (1796), ii. 159.

MERV, MERU or MAUR, an oasis and town of Asia, in the Transcaucasia province of Russia. The oasis is situated on the S. edge of the Kara-kum desert, in 37° 30' N. and 62° E. It is about 280 m. N. from Herat, and 280 S.S.E. from Khiva. Its area is about 1900 sq. m. The great chain of mountains which, under the names of Harapamissus and Hindu-Kush, extends from the Caspian to the Pamirs is interrupted some 180 m. of Merv. Through or near this gap flow northwards in parallel courses the rivers Her-i-rud (Tejend) and Mughab, until they lose themselves in the desert of Kara-kum. Thus they make Merv a sort of watch-tower over the entrance into Afghanistan on the north-west and at the same time create a stepping-stone or stipe between north-east Persia and the states of Bokhara and Samarkand. The present inhabitants of the oasis are Turkomans of the Tekke tribe. In 1897 they numbered approximately 240,000. The oasis is irrigated by an elaborate system of canals cut from the Murghab. The country has at all times been remounved throughout the East for its fertility. Every kind of cereal and many fruits grow in great abundance, e.g. wheat, millet, barley and melons, also rice and cotton. Silkworms are bred. The Turkomans possess a famous breed of horses and keep camels, sheep, cattle, asses and mules. They are excellent workers in silver and noted as armourers, and their carpets are superior to the Persian. They also make felt and a rough cloth of sheep's wool. The heat of summer is most oppressive. The least wind raises clouds of fine dust, which fill the air, render it so opaque as to obscure the noonday sun, and make respiration difficult. In winter the climate is very fine. Snow falls rarely, and when it does, it melts at once. The annual rainfall rarely exceeds 5 in., and there is often no rain from June till October. Here in summer the thermometer goes up to 97° F., in winter it descends to 19° S. The average yearly temperature is 60°. Here is a Russian imperial domain of 436 sq. m., artificially irrigated by works completed in 1895.

History.—In Hindu (the Puranas), Parsi and Arab tradition, Merv is looked upon as the ancient Paradise, the cradle of the Aryan families of mankind, and the birthplace of the human race. Under the name of Mouro this place is mentioned with Bakhdi (Balkh) in the geography of the Zend-Avesta (Vendidad, ed Spiegel, 1825-1863), which dates probably from at least 1200 B.C. Under the name of Margu it occurs in the cuneiform (Behistun) inscriptions of the Persian monarch Darius Hystaspis, where it is referred to as forming part of one of the satrapies of the ancient Persian Empire. It afterwards became a province (Margiana) of the Greco-Syrian, Parthian and Persian kingdoms. On the Margu the Eraduz, or Ariz and now the Murghab—stood the capital of the district, Antiokia Margiana, so called after Antiocchus Soter, who rebuilt the city founded by Alexander the Great.
About the 5th century, during the rule of the Persian Sassanian dynasty, Merv was the seat of a Christian archbishopric of the Nestorian Church. The town was occupied (A.D. 646) by the lieutenants of the caliph Othman, and was constituted the capital of Khorasan. From this city as their base the Arabs, under Kotalba (Qotaila) ibn MusliM, early in the 8th century brought under subjection Balkh, Bokhara, Ferghana and Kasgharia, and penetrated into China as far as the province of Kan-suh. In the latter part of the 8th century Merv became obnoxious to Islam as the centre of heretical propaganda preached by Mokanna (q.v.). In 784 Arabs and Persians in Central Asia came to an end. During the reign of Alp Khan, Merv, like Samarkand and Bokhara, was of Timur-i-Lenk (Tamerlane), Mongo prince of Samarkand. In 1395 the city was occupied by the Ulugs, who five years later were expelled by Ismail Khan, the founder of the Safavid dynasty of Persia. Merv remained in the hands of Persia until 1787, when it was captured by the emir of Bokhara. Seven years later the Bokharans razed the city to the ground, broke down the dams, and converted the district into a waste. When Sir Alexander Burnes traversed the country in 1832, the Khivans were the rulers of Merv. About this time the Tekke Turkomans, then living on the Khuri-rud, were forced by the Persians to migrate northward. The Khivans continued to be the dominant tribe, but ultimately, about 1856, the latter became the sovereign power in the country, and remained so until the Russians occupied the oasis in 1883.

The ruins of Old Merv cover an area of over 15 sq. m. They consist of a square citadel (Bairam Ali Khan kalah), 13 m. in circuit, built by a son of Tamerlane and destroyed by the Bokharans, and another kalah or walled enclosure known as Abdullah Khan. North from these lies the old capital of the Seljuks, known as Sultan Kalah, and destroyed by the Mongols in 1310. Its most conspicuous feature is the burial place of Sultan Sanjar, reputedly dating from the 12th century. East of the old Seljuk capital is Giur Kalah, the Merv of the Nestorian era and the capital of the Arab princes. North of the old Seljuk capital are the ruins of Eskender Kalah, probably to be identified with the ancient Merv of the Seleucid dynasty.

NEW MERV, the present chief town of the oasis, founded in the first quarter of the 10th century, is on the Transcaspian railway, 380 m. by rail south-west from Samarkand. It stands on both banks of the Murghab, 220 ft. above the Caspian. Due north, Bokhara, including Russians, Armenians, Turkomans, Persians and Jews. It has a meteorological observatory. Corn, raw cotton, hides, wool, nuts and dried fruit are exported.

MERX, ADALBERT (1838–1900), German theologian and orientalist, was born at Blecherode near Nordhausen on the 2nd of November 1838. He studied at Jena, where he became extraordinary professor in 1869. Subsequently he was ordinary professor of philosophy at Tübingen, and in 1873 professor of theology at Giessen. From 1875 till his death he was professor of theology of Heidelberg. In the course of his researches he made several journeys in the East. Among his many works are: *Grammatica syriaca* (1867–1870); *Vocabulary of the Tigré language* (1868); *Das Gedicht vom Hioh* (1871); *Die Prophetie des Job und ihre Auslegung* (1879); *Die Saadjanische Übersetzung der Hoheiten der Arabes* (1882); *Chrestomathia targumica* (1888); *Historia artis grammaticae apud Syros* (1890); *Ein samaritanisches Fragment* (1893); *Ideas and Grundlinien einer allgemeiner Geschichte der Mosis* (1893). He devoted much of his later work to the study of the Scriptures, particularly of the Samaritan Pentateuch. (J. T. B.)
never pay. A few years after the completion of his Paris series he was lodged in the madhouse of Charpentier. Its order and care restored him for a while to health, and he came out and did a little more work, but at bottom he was exhausted. In 1867 he returned to his asylum, and died there in 1868. In the middle years of his life, just before he was placed under confinement, he was much associated with Bracquemond and with Flammé,—skilled practitioners of etching, while he was himself an under- notable genius of some of whose water-paintings we have. It is, however, evident that one by Bracquemond under which the sitter wrote that it represented "the sombre Méryon with the grotesque visage."

There are twenty-two pieces in the Eaux-fortes sur Paris. Some of them are insignificant. That is because ten out of the twenty-two were destined as headpiece, tailpiece, or running commentary on some more important plate. But each has its value, and certain of the smaller pieces throw great light on the aim of the entire set. Thus, one little plate—not a picture at all—is devoted to the record of verses made by Méryon, the purpose of which is to lament the life of his cap. The misery of the town Méryon had to illustrate, as well as its splendour. The art of Méryon is completely misconceived when his etchings are spoken of as views of Paris. They are often "views," but they are so just so far as is compatible with their being likewise the visions of a poet and the compositions of an artist. It was an epic of Paris that Méryon determined to make, coloured strongly by his personal sentiment, and affected here and there by the occurrences of the moment—in more than one case, for instance, he hurried with particular affection to etch his impression of some of the scenes building which was on the point of destruction. Nearly every etching in the series is an instance of technical skill, but even the technical skill is exercised most happily in those etchings which have the advantage of impressive subjects, and which the collector willingly cherishes for their mysterious suggestiveness or for their pure beauty. Of these, the Abside de Notre Dame is the general favourite; it is commonly held to be Méryon's masterpiece. Light and shade play wonderfully over the great fabric of the church, seen over the spaces of the river. As a draughtsman of architecture, Méryon was complete; his sympathy with its various styles was broad, and his work on its various styles unbiased and of equal perfection—a point in which it is curious to contrast him with Turner, who, in drawing Gothic, often drew it with want of appreciation. It is evident that architecture must enter largely into any representation of a city, however much such representation may be a vision, and however little a chronicle. Besides, the architectural portion even of Méryon's labour is but indirectly imaginative; to the imagination he has given freer play in his dealings with the figure, whether the people of the street or of the river or the people who, when he is most frankly or even wildly symbolical, crowd the sky. Generally speaking, his figures are, as regards draughtsmanship, "landscape-painter's figures." They are drawn more with an eye to grace than to academic correctness. But they are not "landscape-painter's figures" at all when what we are concerned with is not the method of their representation but the purpose of their introduction. They are seen then to be in exceptional accord with the sentiment of the scene. Sometimes, as in the case of La Morgue, it is they who tell the story of the picture. Sometimes, as in the case of La Rue des Mauvais Garçons—with the two passing women bent together in secret converse—they at least suggest it. And sometimes, as in L'Arche de Noé, by the significant expressive gesture, they convey an emotion that give vitality and animation to the scene. Dealing perfectly with architecture, and perfectly, as far as concerned his peculiar purpose, with humanity in his art, Méryon was little called upon by the character of his subjects to deal with Nature. He drew trees but badly, never representing foliage happily, either in detail or in mass. But to render the characteristics of the city, it was necessary that he should know how to portray a certain kind of water—river-water, mostly sluggish—and a certain kind of sky—the grey obscured and lower sky that broods over a world of roof and chimney.

This water and this sky Méryon is thoroughly master of; he notes with observant affection their changes in all lights.

Méryon's excellent draughtsmanship, and his keen appreciation of light, shade and tone, were, of course, helps to his becoming a great etcher. But a living authority, himself an eminent etcher, and admiring Méryon thoroughly, has called Méryon by preference a great original engraver—so little of Méryon's work accords with Sir Seymour Haden's view of etching. Méryon was anything but a brilliant sketcher; and, if an artist's success in etching is to be gauged by the rapidity with which he records an impression, Méryon's success was not great. There can be no doubt that his work was laborious and deliberate, instead of swift and impulsive, and that of some other virtues of the etcher—"selection" and "abstraction" as Hamerton has defined them—he shows small trace. But a genius like Méryon is a law unto himself, or rather in his practice of his art he makes the laws by which that art and he are to be judged.

It is worth while to note the extraordinary enhancement in the value of many of his prints. Probably no other artist of genius, not even of Whistler, could there be cited within the same period a rise in pieces of at all the same proportion. Thus the first state of Strype's "Fruit with the verses," sold under the hammer in 1873 for £5; in 1875 for £7; and in 1876 for £100. The first state of the "Galérie de Notre Dame," selling in 1873 for £5, and at M. Wasse's sale in 1880 for £1, fetched in 1886 £175. A "Tour de l'Horloge," which has been on the market for three years after it was first issued sold for half a crown in May, 1873. A "Voyage au Bord de la Mer," sold for £1; £7, £20. A first state (Wedmore's, not of course M. Deltel's "first state," which, like nearly all his first states, is in fact a trial proof) of the Etienne du Dur's "Corinna," was selling at £1 in 1876, realized £50 at a sale in May, 1906. The second state of the "Morgue" (Wedmore sold in 1905 for £5; and Wedmore's second of the "Abside," which used to sell throughout the seventies for £4 or £5, reached in November 1906 more than £300. At no period have even Dürers or Rembrandts risen so swiftly and steadily.

Delteil, Charles Méryon (1907); Frederick Wedmore, Méryon and Méryon's Paris, with a descriptive catalogue of the artist's work (1879; 2nd ed., 1892); and Fine Prints (1896; 2nd ed., 1905).

Mescheryaks, or Meshcheryaks, a people inhabiting eastern Russia. Nestor regarded them as Finns, and even now part of the Mordvinians (of Finnish origin) call themselves Meshcheryaks. Klaproth, on the other hand, supposed they were a mixture of Finns and Turks, and the Hungarian traveller Rugulé discovered that the tatarized Meshcheryaks of the Obo closely resembled Hungarians. They formerly occupied the basin of the Oka (where the town Meshchersk, now Meshchovsk, has maintained their name) and of the Sura, extending north-east to the Volga. After the conquest of the Kazan Empire by Russia, part of them migrated north-eastwards to the basins of the Kama and Byelaya, and thus the Meshcheryaks divided into two branches. The western branch became russified, so that the Meshcheryaks of the principal possessions of Penza, Saratov, Ryazan and Vladimir have adopted the customs, language and religion of the conquering race; but their ethnographical characteristics can be easily distinguished in the Russian population of the governments of Penza and Tambov. The eastern branch has taken on the customs, language and religion of Bashkirs, with whom their fusion is still more complete.

Meshed (properly Meshhad, "the place of martyrdom"), capital of the province of Khorasan in Persia, situated in a plain watered by the Khashaf-rud (Tortoise river), a tributary of the
Hari-cud (river from Herat, which after its junction with the Khashal is called Tejen), 460 m. E. of Teheran (550 by road) and 200 m. N.W. of Herat, in 36° 17’ N., 59° 30’ E., at an elevation of 3,800 ft. Its population is about 70,000 fixed and 10,000 floating, the latter consisting of pilgrims to the shrine of Imam Reza.1

The town is of irregular shape, about 6 m. in circumference and surrounded by a mud wall flanked with towers. In the south-western corner of the enclosure stands the citadel (ark), within a wall 25 ft. high and a broad dry ditch which is 40 ft. deep in parts and can be flooded from without by a sally-port. The course of the town is confined by the walls of the fort. The city has five gates, and from one of them, called Bala Khiaban gate (upper Khiaban), the main street (Khiaban), 25 yds. broad, runs in a north-west-south-east direction, forming a fine avenue planted with plane and mulberry trees and with a stream of water running down its middle. The shrine of Imam Reza is the most venerated spot in Persia, and yearly visited by more than 100,000 pilgrims. Eastwick thus describes it (Journal of a Diplomat’s Three Years’ Residence in Persia, London, 1864–65):

‘...the dome of the shrine seemed to be about 150 paces square. It was paved with large flagstones and in the centre was a beautiful kiosk or pavilion, covered with gold and raised over the reservoir of water for ablutions. This pavilion was built by Nadir Shah in the centre of the northern, western and southern sides of the quadrangle ran, at some 10 ft. from the ground, a row of alcoves, similar to that in which I was sitting, and filled with mullas in white turbans and dresses. In each of the sides was a gigantic archway, the height of which was a square from the gravel of the floor to the top of the dome. The height to the top of this square wall must have been 90 or 100 ft. The alcoves were white, seemingly of stone or plaster; but the arches were built with blue or varnish blue, with beautiful inscriptions in white and gold. Over the western archway was a white cage for the muzzins, and outside it was a gigantic minaret 120 ft. high, and as thick as the Duke of York’s column in London. The beauty of this minaret cannot be exaggerated. It had an exquisitely carved capital, and above that a light pillar, seemingly 10 ft. high; and this and the shaft below the capital, or about 20 ft., were covered with gold. All this part of the mosque (shrine) was built by Shah Abbas. In the centre of the eastern side of the quadrangle two gigantic doors were thrown open to admit the people into the aytum or inner mosque (shrine) where is the marble tomb of Imam Reza, surrounded by a silver railing with knobs of gold. There was a flight of steps ascending to these doors, and beyond were two smaller doors encrusted with jewels—the rubies were particularly fine. The inner mosque would contain 30,000 persons. Over the rose a dome entirely covered with gold, with two minarets at the sides, likewise gilt all over. On the right of the Imam’s tomb is that of Abbas Mirza, grandfather of the reigning Shah.2 Near him several other princes and chiefs of note are interred, and the golden rings, knives and swords, in striking contrast with it, was a smaller dome of bright blue. Here begins the mosque of Gauhar Shad.3 The quadrangle is larger than that of Shah Abbas; and at the inner side is an immense blue dome, out of which quantities of grass were growing, the place being too sacred to be disturbed. In front of the dome rose two lofty minarets covered with blue tiles. In the boulevard of the Bala Khiaban is a kitchen supported by the revenues of the shrine, where 800 persons are fed daily.

The buildings of the shrine together with a space extending to about one hundred yards beyond the gates of the shrine on each side is sanctuary (bašt). Within it are many shops and lodgings, and criminals, even murderers, may live there in safety. The only other notable buildings in the place are some colleges (medresah), the eldest being the M. Do-dar, i.e. ‘college of two doors,’ built in 1439 by Shah Rukh, and some fine caravan-serals, two dating from 1680.

Without the pilgrims who come to visit it, Meshed would be a poor place, but lying on the eastern confines of Persia, close to Afghanistan, Russian Central Asia, and Transcaspia, at the point where a number of trade routes converge, it is very important politically, and the British and Russian governments have maintained consulates-general there since 1889. Meshed had formerly a great transit trade to Central Asia, of European manufactures, mostly Manchester goods, which came by way of Trebizond, Tabriz and Teheran; and of Indian goods and produce, mostly muslin and spices from Bombay and green teaz, of which much was carried by caravan and by sea to Tabriz. The transit trade had been practically nil. In 1896 General Maclean, the British consul-general, reported that there were 650 silk, 40 carpet and 320 shawl looms at work. The carpet-looms at work now number several hundreds, while looms of silk and shawl number less than half what they did in 1890.

Meshed took telegraph (since 1876) and post (since 1879) offices, and the Imperial Bank of Persia opened a branch here in 1891. The climate is temperate and healthy. The coldest month is January, with a mean temperature of about 32°F., while the hottest month is July, with a mean temperature of 78°F. The highest temperature recorded in a period of six years was 91°, the lowest 15°. The mean annual rainfall during nine years (1890–90) was nearly 9 in., about one-eighth of it being represented by snow.

MESHREBIYA (drinking places), the Arabic term given to the projecting oriel windows in Cairo, enclosed with lattice-work, through which a good view of the street can be obtained by the occupants without being seen; the term was derived from the small semicircular bows, in which porous water-bottles are placed to cool by evaporation in the air.

MESMER, FRIEDRICH (or FRANZ) ANTON (1733–1819), Austrian doctor, from whose name the word ‘Mesmerism’ was coined (see HYPONOTISM), was born at Weil, near the point at which the Rhine leaves the Lake of Constance, on the 23rd of May 1733. He studied medicine at Vienna under the eminent masters of that day, Van Swieten and De Haen, took a degree, and commenced practice. Interested in astrology, he imagined that the stars exerted an influence on beings living on the earth. He identified the supposed force first with electricity, and then with magnetism; and it was but a short step to suppose that stroking diseased bodies with magnets might effect a cure. He published his first work (De planetarum influento) in 1766. Ten years later, on meeting with J. J. Gassner in Switzerland, he observed that the priest effected cures by manipulation alone. This led Mesmer to discard the magnets, and to suppose that some kind of occult force resided in himself by which he could influence others. He held that this force permeated the universe, and more especially affected the nervous systems of men. He removed to Paris in 1775, and in a short time the French capital was thrown into a state of great excitement by the marvellous effects of mesmerism. Mesmer soon made many converts; he excited the indignation of the medical faculty of Paris, who stigmatized him as a charlatan; still the people crowded to him. He refused an offer of 20,000 francs from the government for the disclosure of his secret, but it is asserted that he really told all he knew privately to any one for 100 louis. He received private rewards of large sums of money. His consulting apartments were dimly lighted and hung with mirrors; strains of soft musical music occasionally broke through the profound silence; and the patients sat round a kind of vat in which various chemical ingredients were concocted. Holding each others’
hands, or joined by cords, the patients sat in expectancy, and then Mesmer, dressed in the dress of a magician, glided amongst them, affecting this one by a touch, another by a look, and making "passes" with his hand towards a third. Nervous ladies became hysterical or fainted; some men became convulsed, or were seized with palpitations of the heart or other bodily disturbances. The government appointed a commission of physicians and members of the Academy of Sciences to investigate these phenomena; Franklin and Baillie were members of this commission, and drew up an elaborate report admitting many of the facts, but contesting Mesmer's theory that there was an agent called animal magnetism, and attributing the effects to physiological causes. Mesmer himself was undoubtedly a mystic; and, although the excitement of the time led him to indulge in mummeries and sensational effects, he was honest in the belief that the phenomena produced were real, and called for further investigation. For a time, however, animal magnetism fell into disrepute; it became the system of a downright juggler, and Mesmer himself was denounced as a shallow empiric and impostor. He withdrew from Paris, and died at Meersburg in Switzerland on the 5th of March 1815. He left many disciples, the most distinguished of whom was the marquis de Puységur.

MESNAGHER (or Le Mesnager), NICOLAS (1658-1714), French diplomat, belonged to a wealthy merchant family. He gave up a commercial career for the law, however, and became advocate before the parlement of Rouen. In 1700 he was sent as deputy of Rouen to the council of commerce, which was established in Paris for the export of French trade. Here he made his mark, and was chosen to go on three missions to Spain, between the years 1704 and 1705, to negotiate financial arrangements. In August 1711 he was sent on a secret mission to London to detach England from the alliance against France, and succeeded in securing the adoption of eight articles which formed the base of the later Treaty of Utrecht. As a reward for his skill he was made one of the three French plenipotentiaries sent to Utrecht in January 1712, and had the honour of signing the treaty the next year. As he had used much of his own large fortune to keep up his state as ambassador, he was granted a pension by the grateful king of France. His portrait by Hyacinthe Rigaud is in the gallery of Versailles.

MESNE (an Anglo-French legal form of the O. Fr. meien, mod. moyen, mean, Med. Lat. medium, in the middle, cf. "mean"), middle or intermediate, an adjective used in several legal phrases. A mesne lord is one who has tenants holding under him, while himself holding of a superior lord. Mesne process was such process as intervened between the beginning and end of a suit (see Process). Mesne profits are profits derived from lands which were claimed in damages for trespass either in a separate action or joined with an action for the recovery of the land. The plaintiff must prove that he has re-entered into possession, his title during the period for which he claims, the fact that the defendant has been in possession during that period, and the amount of the mesne profits. The amount recovered as mesne profits need not be limited to the rental value of the land, but may include a sum to cover such items as deterioration or reasonable costs of getting possession, &c.

MESOCEPHALIC, a term applied by anthropologists to those skulls which exhibit a cephalic index intermediate between the dolichocephalic and brachycephalic crania (see CRANIOMETRY). Taking the longer diameter of a skull, i.e., the one from front to back, as 100, mesocephalic skulls are those of which the transverse diameter varies between 75 to 80.

MESODES of Crete, Greek lyric poet, who lived during the 2nd century a.d. He was a freedman of the emperor Hadrian, on whose favourite Anthus he is said to have written a panegyric. Two epigrams by him in the Greek anthology (Anthol. poët. iv. 63, xvi. 323) and a hymn to Nemesis are preserved. The hymn is of special interest as preserving the ancient musical notation written over the text. Two other hymns—to the muse Calliope and to the sun—formerly assigned to Dionysius of Alexandria, have also been attributed to him.

See J. F. Bellermann, Die Hymnen des Dionysius und Mesodesmes (1840); C. de Jan., Musici scriptores graeci (1899); S. Reinach in Revue des études grecques, iv. 66, and other writings.

MESONERO ROMANOS, RAMÓN DE (1803-1882), Spanish prose-writer, was born at Madrid on the 10th of July 1803, and at an early age became interested in the history and topography of his native city. His Manual de Madrid (1831) was published when literature was at a low ebb in Spain; but the author's curious researches and direct style charmed the public, and next year his novel entitled Caritas españolas, under the pseudonym of "El Curioso parisiense," appeared. In 1835 and 1836, he published social life of the capital which were subsequently collected and called Panorama matritense (1835-1836). Mesonero Romanos was elected to the Spanish Academy in 1838 and, though he continued to write, had somewhat outlived his fame when he issued his pleasing autobiography, Memorias de un setentón, natural y vecino de Madrid (1880). He died at Madrid on the 30th of April 1882, shortly after the publication of his Obras completas (8 vols., 4to, 1881).

MESOPOTAMIA (Mésopotamía, sc. χώρα or Σηπρα, from μεσός, middle, ποταμός, river), one of the Greek renderings of the earlier Semitic names for the river-country that stretches eastward from northern maritime Syria. The earliest appearance of a Semitic name of this kind is in the last paragraph of the biography of Aḥmōsē of el-Kāb, the aged officer of Tethmosis (Thutmose) I. As early therefore as the late 16th century B.C. the name Naharin (N'hr'yn) was in use. That the name was connected with nahar (a river) was plain to some of the Egyptian scribes, who wrote the word with determinative for "water" in addition to that for "country."

The scribes show no suspicion, however, of the name's being anything but a singular.1 Is it possible that a consciousness that the word was not a plural can have survived till the early Christian period? For example, when the Talmud (Gen. R. 2. 12) speaks of the "river Euphrates" (Pethor of Aram which is on the Euphrates: Deut. xxiii. 4 [5])? The Naharin or Naharen of the Egyptian texts appears some five generations later in the Canaanite of the Amarna letters in the form Naḥrim (n), which would seem therefore to be the pronunciation then prevalent in Phoenicia (Gebal) and Palestine (Jerusalem). About the same time Naharin (N-ny-r)n is given as the northern boundary of Egypt's domain (year 30 of Amenhotep or Amenophis III.), over against Kush in the south (tomb of Khamhet; Breaded, Anc. Rec. ii. 350).

The origin of the name is suggested by the Euphrates being called the water of Naharin,"—on the Kanakrale more fully, the water of the Great Bend (pīy gu) of Naharin (N-h-r)n " (Breaded, Anc. Rec. ii. 263), or on the Constantinople obelisk simply "the Great Bend of Naharin" (loc. cit., note d). The precise, mean-2

1 The threefold n after Nahor in a stele of Persian or Greek times (healing of Bentresh) is probably only the determinative for "water," a fourth n being accidentally omitted (Breaded, Ancient Records, iii. § 434).

2 Paddan-Aram (Rev. Ver., better Paddan-Aram), Gen. xxy. 20, &c., rendered by the Septuagint Mesopotamia of Syria, is obscure. Paddan has been connected phonetically with Paltin, west of the Euphrates, and explained by others as a synonym for Harran.
MESOPOTAMIA

4 = D. The Syriac version of the Old Testament (2nd cent. A.D.? ) uses Bēth Nahrin. This may or may not imply the belief that Nahrin is a plural. Eventually that belief was general, as is proved by the Aramaic form (the normal Aramaic plural form of a masculine) in the alternative form Bēth Nahrawāthā (e.g., Wright, Chron. Joshua Sty. §§ 49, 50). Bēth is probably the Syriac equivalent of the Assyrian Bit (the usual form below the 40th Parallel), although, as Bēth Arbīyē, "district of Arabians," Bēth Armāyē, "district of Arameans," the Parapotamia of Strabo xvi. 2, 11, would be a suitable Greek equivalent. Mesopotamia seems to imply the view that Bēth is the interpretation of Bit, which has the same form,1 but need not imply the meaning "between." That is, the idea that there were precisely two rivers. There is evidence of the use of this form as early as the Septuagint translation of Genesis i. 9, where the word is not even the interpretation of Bit, which was adopted by the Greeks who accompanied Alexander's expedition. Xenophon does not use it.

So in John of Ephraem (d. A.D. 373) the use of the Syriac Götirētē, "island," had come in, and over a century earlier Philostratus reported (Life of Apollonius, i. 20) that the Arabs designated Mesopotamia as an island.2 This term in the form al-Götirētē became and still is, the usual Arabic name.

The absence of any equivalent names in Babylonian or Assyrian documents is noteworthy,3 especially as the Babylonians spoke the Sea-Country "tamit Tānilē". The name was not distinct enough from the point of view of Babylonians to the same water system. Tigrath-pilser I. (Octagon Prism, 6, 40, 42 seq.) sums up the results of the military operations of his father Tigrath-pilser I., who reached from the Lower Zab rivers to the Upper Euphrates Rivierē (ebisian Purāti, well rendered "Parapotamia" by Winckler4) and Hatte-land; but this is obviously not a proper name in the same sense as Naharin.5 That probably originated in Mesopotamia, or the isle of Syria.

Whilst the names we have mentioned are derived from physical geography, there are related names the meaning and origin of which are uncertain. Tether (v. 24, 21) said, in a tomb which contains a picture of "the chief of Khita," to have "overthrown the lands of My-tn" (Breasted, Anc. Rec. ii. § 773), which lands are mentioned also in his hymn of victory (Breasted, Anc. Rec. ii. 10, 21, referred to from the "river of My-tn" (Breasted, Anc. Rec. ii. § 804). In the bilingual Hittite inscription of Tarqumdethe name is called "the land of the city of Metan," just as in the Hittite documents the Hittite country in Asia Minor is called "the land of Metan," the landing-place of the Hittite kings. It is clearly the same as Mittani, over against Khatti, mentioned e.g. by Tighlath-pilser I. (vi. 63), which is the same as Mittani, several letters from which are in the Amarna collection. Since a Mittani princess of these letters is called the Egyptian scarab a princess of Naharin, it is clear that Mittani and Naharin are more or less equivalent, whilst in the Amarna letters even Tushratta, the king of Mitanni, seems to use in the same way the name Khatin-galbat. A shorter form of this name is Khatin, which it is difficult not to connect with Khana, the capital of which at one time was Tira, on the Euphrates, below the Khābar (see § 4). The slowly advancing reach of the possidation of Naharin, the possession of the doctors precisely the probably varying relations of these various names. The great astrological work uses a term of still wider significance, Sumer Tērēnēti (written Tērēnētē) (especially Winckler's discussion in Or. Lit.-Zelt., 1909). This represented the four quarters of the world in the early Babylonian view, the other three being Akkad (i.e. Babylonia) in the "south," Elam in the "west," and Amurru in the "east." It appears to have denoted the territory above Babylonia stretching from Asshan in the southeast-north westwards, across the Tigris-Euphrates district, indefinitely towards Asia Minor. At an early time it seems to have formed along with Asshan a distinct kingdom.

Strabo (xvi. 746) makes the south limit of Mesopotamia the Median wall; Pliny (v. 24 § 21) seems to extend it to the Persian Extent. The Latin term naturally varied in meaning with the changing extent of Roman authority. For example, under Trajan Mesopotamia reached the gulf and was bounded by Assyria and Armenia. In modern times it is often used for the whole Euphrates-Tigris country. That would provide a useful name for an important geographical unit, but is too misleading. In view of historical and geographical facts there is much to be said for applying the name Mesopotamia to the country drained by the Khābar, the Beliḫi, and the part of the Euphrates connected therewith. It would thus include the country lying between Babylonia on the south and the Armenian Taurus highlands on the north, the maritime Syrian district (Lebanon Mounts). While that is a somewhat broader extension than the Mesopotamia of the Semitic scholarship, it is practically the sense in which it is treated in this article.6 We may begin, however, with the definition of Jēṣur by the Arabic geographers, who take it as representing the central part of the Euphrates-Tigris system, the part, namely, lying between the alluvial plains in the south and the mountainous country in the north. Measured on the Euphrates, this would be from the place where the river, having bored its way through the rocks, issues on to the high plain a little above Samṣât (Samosata) only 1500 ft. above the sea, to somewhere about Hit (Is. 1=Id), where, probably less than 150 ft. above the sea, it begins to make its way through the alluvial deposits of the last few millennia. In these 750 m. it has descended less than 1400 ft. Measured on the Tigris Mesopotamia would stretch from somewhere between Jezreel-ibn-'Omar and Mūsālā to somewhere below Tekrit.

In the tract defined, physical changes unconnected with civilization have been slight as compared with those in Babylonia; the two great rivers, having cut themselves deep channels, could not shift their courses far.

1. Natural Divisions.—The stretch from Samṣât and Jezreel-ibn-'Omar to the alluvial plain seems to divide itself naturally into three parallel belts, highland watershed districts, undulating plains and steppe.

2. Geography. The barrier that shuts off the east to west course of the Euphrates and Tigris culminates centrally in the rugged volcanic Karaja-Dğir (17,300 ft.) a range which, breaking the alluvial plain eastwards by the mountainous district of Tūr-Abdin (the modern capital Mīdāt is at a height of 3500 ft.) and westwards by the elevated tract that sends down southwards the promontory of J. Tektek (c. 1500 ft.).

3. At the line where this east to west wall ends begins the sea of undulating plains where there is enough rain for abundant wheat and barley.

4. From the alluvial flats upwards toward the undulating plains is an extensive stretch of steppe land almost destitute of rain... Not far above the transition from the barren steppe is a second mountain wall (125 m. between extremities) roughly parallel with the first, consisting of a long line of uplands known as the "Taurus Chain" (Al Kūrā), continuing westwards after a marshy break by the volcanic Tell Kōkab (basalt, about 1300 ft.), and then the "Abd al-'Azīz range" (Belkh), veering its western end as if to meet the Tektek promontory from the north.

5. Drainage.—The water system is thus determined. West of Tektek drains into the Beliḫi, east of Tektek into the Khābar. The river course eastwards. The rivers and drainage, the Beliḫi and the Beliḫi, is towards the left bank of the Euphrates, for the Mesopotamian watershed seems to be only some 15 m. or less from the Tigris until, south of the Sinjar range, it lies farther west, and the Tharthār river is possible. The Beliḫi (Baleb, Bilekkas, Belkhāji), a stream some 30 ft. wide, has its main source some 50 m. north in the 'Ain Khalīl ar-Ra'sā, but receives also the waters of the united Nahr al-Kūt (in its upper course formerly the Malšīn, Sīkrap) from Edessa and Köprü Dāg, and the Jullāb from Tektek Dāg about as much farther north. The Khābar (Chabur, Chabrā), 80–100 ft. wide, before its last 40 m. reach in a southeast direction, has its source, however, many miles to the south from Tell Kūkab (about 1300 ft.), near which are united the Jaggāh (earlier, Harrās, 20 ft. in width), which has come 50 m. from Naṣībin in the north-east, bringing with it the water of the many streams from the Tūr 'Abdīn highlands; the north 'Awīj, which at certain points brings much water due south from Mārdīn, and the main stream of the Khābar, which has come 60 m. from Ras al-'A'in in the north, which also the gap between the ranges of Naṣībin and the Tūr 'Abdīn, continues, at the point of the Sinjar range, southwestwards, cutting in this Sinjar range and runs southwards, to lose itself in the desert a little above the latitude of Hit. So it seems to the geographer (Anab. i. 21) and the Armenians (Nem., Schei, 1909). The Arabic geographers represent the Tharthār as connected at its upper end (by a canal?) with the Khābar system.

5. In general the Tigris is considered to belong to Assyria or Babylonia, and all west of the Euphrates to Arabia or Syria.

7. Ibid. xi. 253–265.
iii. Character of its Surface.—(1) The tract between the Belihk and the Euphrates is in its middle section exceedingly fertile, as is implied by 1. Anathematis and associated with the name of Zeus, Deidamia, and Asclepius. 2.p. 491–492. 3. see city of Tirga. 4. see city of Tirga. 6. see city of Bar.
concession with the north, and Asia Minor, goes back to a very early date. It may be that some of the early north Babylonian kingdoms, such as Khis, extended control thither. The earliest Babylonian monarch of whose presence in Mesopotamia there is positive evidence is Lugalzaggesi (before 2150 B.C.), who claims, with the help of En-IlI, to have led his countless host victorious to the Mediterranean. His empire, if he founded one, was before long eclipsed, however, by the rising power of the Semites. Excavation in Mesopotamia may in time cast some light on the questions whether the Semites really reached Babylonia by way of Mesopotamia,1 when, and whom they found there, and whether the Hittites partly settled there by the way. Whether Sharru-GI and Shargani-sharri (often called Ururu-mush) really preceded, and to some extent anticipated, "Sargon" i.e. Shargani-sharri, as L. W. King now2 plausibly argues, is not certain; nor whether the 32 kings who revolted and were conquered by Manishtus, as we now learn, were by the Mediterra-

1 The Chronicle 26,472 may be, as Winckler argued (Or. Lit.-Zelt. 1907, col. 296), an introduction of new elements into Suri—in that case perhaps one of the early representatives of the "Hittite" group. According to the Omens the text Sargon seems to have settled colonies in Suri, and suggestions of an anticipation of the later Assyrian policy of transportation have been put forward by King (op. cit.) under the rulers of this time, and there are evidences of lively intercommunication. Mesopotamia certainly felt the Semero-Babylonian civilization early. It was from the special type of cuneiform developed there, apparently, that the later Assyrian forms were derived (Winckler, Allorient. Forsch. i. 86 seq.). What the "revolt of all lands" ascribed to the later part of Sargon's reign means is not yet clear; but he or his son quickly suppressed it. Mesopotamia would naturally share in the wide trade relations of the time, probably reaching as far as Egypt. The importance of Harran was doubtless due not only to its fame as a seat of the Moon-god Sin, honoured also aet of the Hittites, and to its political position, but also to its trade relations. Contemporary records of sales of slaves from Amurru are known.

When the Semitic settlers of the age of Sargon, whom it is now common with some justice to call Akkadians (see SUMER), had become thoroughly merged in the population, there appeared a new immigrant element, the Amurru, whose advance as far as Babylonia is to be traced in the troubled history of the post-

Gudean period, out of the confusion of which there ultimately emerged the Khumarabi dynasty. That the Amurru passed through Mesopotamia, and that some remained, seems most probable. Their god Dagan had temple at Turqa (near Ishara, a little below Circeium), the capital of Khana (several kings of which we now know by name), probably taking the place of an earlier deity. At Turqa they had month names of a peculiar type. It is not improbable that the incorporation of this Mesopotamian kingdom with Babylon was the work of Kham-

2 The preceding note.

murabi himself.

Not quite so successful eventually was the similar enterprise farther north at Assur (or Assur, q.v.) on the east margin of Mesopotamia, although we do not know the immediate outcome of the attempt to make Assur and the first Babylonian king, Sumu-abu. Possibly the rulers of Babylon had a freer hand in a city that they apparently raised to a dominant position than the Semitic rulers of Assur, who seem to have succeeded to men of the stock which we have hitherto called Mittani, if we may judge from the names of Ushpia who, according to Shalmanesser I. and Esarhaddun, built the temple, and Kikia, who, according to Asshur-rem-nisheshu, built the city wall.3 The considerable number of such names already found in First Dynasty records seems to show that people of this race were to be found at home as far south as Babylonia. Whether they were really called Shubaru, as Ungnad suggests, we may know later.

When Khammurabi's fifth successor saw the fall of the Amorite dynasty in consequence of an inroad of "Hittites," these may have been Mesopotamian Shubaru-Mittani, but they may, as Ungnad suggests, represent rather another branch of the Hittites, the Hattites. In some such case in any case not to connect with this catastrophe the carrying away to Khani of the Marduk statue afterwards recovered by Agum, one of the earlier kings of the Kassite dynasty. Whether Hittites were still resident at Khana we do not know. The earlier Kassite kings of Babylon still maintained the Amorite claim to the four quarters; but it is improbable that there was much force behind the claim, although we have a document from Khana dated under Khashillilash. It is just as uncertain how long Assur remained under the Babylonian suzerainty which the text ascribes to Sargon.3 As the fifth century after his death is traced on the face of the monuments, and as the relation of Assur to western Mesopotamia was under the early kings whose names have lately been recovered. All these matters will no doubt be cleared up when more of the many tells of Mesopotamia are excavated. Only two have been touched: 'Arbân on the Khâbûr, where remains of a palace of uncertain date, among other things an XVIII. dynasty scarab, were found by Layard in 1851, and Tell Khalaif, where the confusions join, and remains of the palace of a certain Kapar, son of Hanpan of "Hittite" affinities but uncertain date, were found by Oppenheim in 1899. A long inscription of a certain Shamshi-Adad (Samshi-Haddâl), extracts from which are quoted by Delitzsch (Mitt. d. Deutsch Or.-Gesellschaft. No. 21 p. 50), unfortunately cannot be dated exactly, or with certainty even approximately; but if Delitzsch and Ed. Meyer are right, it belongs to a time not many generations after Agum recovered the Marduk statue. Shamshi-Adad's claims extend over the land between the Tigris and the Euphrates, and he says that he erected memorials of himself on the shore of the Great Sea.

The mystery of the Hyksos has not yet been solved; but it is not impossible that they had relations with Mesopotamia.4 A late date has been given to the Euphrates, and even to the name of Hittite, by Schrader, an officer of Tuthmosis (Ftutmoses) I., mentions Naharin (late 16th century), he does not say anything about the inhabitants. He seems to imply, however, that there was more than one state. The first mention of Mitanni, as we see, is under Tuthmosis III., who clearly crossed the Euphrates. It is at least possible that common cennity to Mitanni led to a treaty with Assyria (under Asshur-nadin-akhe).5 Victorious expeditions into Naharin are claimed for Amenophis II., Tuthmosis IV. and Amenophis III. The Egyptian references are too contemptuous to name the Euphrates, but Shaushtatar may have begun his reign during the life-time of Tuthmosis III., and from cuneiform sources we know the names of six other Mitanni rulers. As they all bear Arayan names, and in some of their treaties appear Arayan deities (Inara, Varuna, Mithra, &c.), it is clear that Mesopotamia had now a further new element in its population, bearing apparently the name Harrâr. Many of the dynasts in North Syria and Palestine in the time of Tushratta bear names of the same type. The most natural explanation is that Arays had made their way into the highlands east of Assyria, and thence lands had penetrated into Mesopotamia, peacefully or otherwise, and then, like the Turks in the end of the Cimmerian (p. 82) dynasties, the language of the Mitanni state, however, was neither Arayan nor Semitic, and may very well be that of the mysterious "Hittite" hieroglyphic inscriptions (see HITITES). Mitanni was one of the great powers, alongside of Egypt and Babylonia, able to send to Egypt the Ninevite 'Istar; and at this time as much as at any other.

1 Ungnad, Beitr. z. Assy. VI. v. 13.

3 Winckler has identified the Khari with the Arays, to whom he assigns a state in Armenia (Or. Lit.-Zelt., July 1910).

other, we must think of common political relations binding the districts east and west of the Euphrates. The king mentioned above (Shaushatar) conquered Assur (Assur), and Assyria remained subordinate to Mitanni till near the middle of the 14th century, when, on the death of Tushratta, it overthrew Mitanni with the help of Alshe, a north Mesopotamian state, the allies dividing the territory between them. The Hititte king's intervention restored the Mitannite state as a protectorate, but with a smaller territory, probably in the north-west, where it may have survived long.

Assyria was now free, and Ashur-uballit (Assur-yyahalidh acc. to Sayce) knew how to make use of his opportunities, and, in the words of his great grandson, "broke up the forces of the widespread Shubari" (AKA, p. 7, 132 seq.). Knowing what we know of the colonizing power of the Assyrians, we may assume that among the "Mitanni" and other elements in the Mesopotamian population there would now be an increase of people of "Assyrian" origin. On the tangled politics of this period, especially Mesopotamia's relations with the north-west, the Boghaz-Keui documents may be expected to throw a great deal of light. We have already a little more of the decipherment of the Amorites in the Naharin district, best by great powers on three sides. When Mitanni fell Babylon no doubt adhered to its older claims on Mesopotamia; but the Kassite kings could do little to contest the advance of Assyria, although several rectifications of the boundary between their spheres are reported.

Mitanni's fall, however, had opened the way for others also. Hence when Ashur-uballit's grandson, Ani-den-il (written Arameans. PU.DI.III), carried on the work of enforcing Assyria's claim to the heriship of Mitanni, he is described as conquering the regions (1) of the Akhlam and the Suti. The references to these people, who practically make their first appearance in the Amarna correspondence, show that they were unsettled bands who took advantage of the looser authority to introduce themselves into various parts of the country, in this case Mesopotamia. Gradually settlements were made, the names of many of which are given by the various Assyrian kings who had at one time or another to assert or reassert supremacy over them—such as Chindanu, Laqa, Subi along the South Euphrates boundary of Mesopotamia, and various districts bearing names compounded with Bit (= settlement) (see above), such as Bit-her (the later name of the Oreezoi, see Eressa), or Bit-Zamani in the north near Dirbehk. The specific name Aramea first appears in the annals of Tiqath-pilser I., unless we identify the Arimi of Shalmaneser I. in Tör 'Abdin with the Aramu; but the name may probably with fitness be applied to a very large number of the communities mentioned from time to time. Their position in Mesopotamia must have been very like that of the Shammar at the present time (see ad fin.). As they gradually adopted settled life in various parts of the country the use of Aramaic spread more and more (see below, § 6 "Persian").

Meanwhile Mesopotamia continued to be crossed and recrossed by the endless marches of the Assyrian kings (such as Adad-nirari, Shalmaneser I. and his son), building and rebuilding the Assyrian empire (see BABYLONIA AND ASSYRIA), and eventually pushing their conquests towards Asia Minor at the expense of the Hititte domain. II., on the fall of the Kassites, Nebuchadrezzar I. established more direct relations between Mesopotamia and Babylon, his work was presently undone by the vigorous campaigns of Tiqath-pilser I., who seems to have even won Egypt's submission of his succession to the Hititte claims. The newly recovered (1909) tablet of Tukulti-Ninib, the grandfather of Shalmaneser II., is interesting from its account of an expedition down the course of the Tigris to IT=ID (river and town now first mentioned in cuneiform sources) and up the Euphrates to the Khatbar district.

Now that Mesopotamia had passed out of the hands of Babylon, all that the later kings could do was to encourage local Mesopotamian rulers in their desire for independence (Nabu-apluiddin). These were convinced that Assyria was master, but refused their tribute when they thought they dared. To thoroughly overpower the troublesome Bit-Adini (see above, § 8, viii.), which had naturally been aided by the states west of the Euphrates, Shalmaneser II. (880-859) settled Assyrians in their midst. Harran was one of the few places that remained on his side during the great insurrection that darkened his last years. Similarly the province of Guzanu (Hhur, Cuna, 'Anaqwærî), on the Khabur, held with the capital Asshur in the insurrection that occurred in 763 (the year of the eclipse), when evidently some one (an Adad-nirari?) wore the crown, at least for a time. Harran was clearly closely associated with Asshur in the rights and institutions that were the subject of so much party struggle in the new Assyrian empire that began with Tiqath-pilser IV. (see BABYLONIA AND ASSYRIA). When the policy of transporting people from one part of the empire to another was developed, new elements were introduced into Mesopotamia, amongst them the Bit-hurrians, whom the Oreezoi and the Harranites, and Qari (see above), may have been more organically attached to the Assyrian state as such than the older inhabitants, to whom the affairs of state at Nineveh would be of little interest. On the conditions at Harran some light is thrown by the census partly preserved in Ashurbanipal's library. The governors of several Mesopotamian cities, such as Nasîhin, Amid, took their turn as eponyms; but this would not have much significance for the people. Hence even the fall of Nineveh (609 b. c.), apart from what such cities in Mesopotamia as held by its last kings suffered through the invasion, first perhaps of Nabopolassar, who in 605 c. n. claims to be lord of Shubari, and then of the Medes, would be a matter of comparative indifference; tribute paid to Babylon was just as hard to find as if it were going to Nineveh. Ninec he did not succeed, like his great XVIIIth dynasty predecessor, in crossing the Euphrates. He was defeated by Nebuchadrezzar at Carchemish (605 n. c.), and Mesopotamia was confirmed to Babylon. Its troubles began again shortly after Nebuchadrezzar's death; the Medes seized Mesopotamia and besieged Harran. Before long, however, the overthrow of Asyages by Cyrus cleared Mesopotamia, and Nabonidus (Nabû-nidus) was driven drawing on the resources of the whole of Syria for the purpose, to restore the famous temple of Sin at Harran, where a few years later he erected in memory of his mother, who seems to have been a priestess there, the stele published in 1907 by Pogon.

The fragmentary nature of the records does not enable us to follow the steps by which Cyrus became master of Mesopotamia, in which he probably met with little or no resistance. Persians. How much of Mesopotamia was involved in the revolt of what the Persian inscription calls Assyria (Atur) is not clear. Nor does it appear with certainty to which of the twenty sapaties into which, according to Herodotus, the Persian empire was divided, Mesopotamia belonged; probably it was included in 'Abar nahârâ. The fact is, we have no information from native sources. The probability is that conditions remained very much what they had been; except that the policy of transportation was not continued. The sapaties and other high officials would naturally be of Persian extraction; but local affairs were probably managed in the old way, and there was no important shift of population. The language and culture of Mesopotamia had by this time been merged in the general body of the people. These settlers doubtless influenced the "Assyrian" language; but gradually, especially in the west, their own language more
Mesopotamia and more prevailed. Although Aramaic inscriptions of the Assyrian period, like those of Zanjífer or that of King ZKR of Hamath, have been found in Mesopotamia, he only in the time of Shalmaneser II. mention is made of an Aramaean letter (Harper, *Ass. Bab. Letters*, No. 872, obv. l. 10), and Aramaic notes on cuneiform documents begin to appear. Weights with Aramaic inscriptions (the oldest from the reign of Shalmaneser IV., 727–22) were found at Calah. By the Achaemenian period Aramaic had become the international language, and was adopted officially.

How Mesopotamia was affected by the passing of Persian armies on their way to suppress revolts in Syria or Egypt, or to conquer them, we do not know from the whole it probably enjoyed unwonted peace. The expedition of Cyrus the Younger, with which Xenophon has made us so familiar, only skirted the left bank of the Euphrates. The route followed by Alexander, though he also crossed at Thapsacus, took him unresolved across the northern parts; but the poor people of Mesopotamia suffered from the measures taken by their satrap Mazaeus to impede Alexander's progress. In spite of this, where Cyrus failed Alexander succeeded.

What would have happened had Alexander lived we can only guess. Under the Sidetes Babylon was moved across the plain to Seleucia; but before long the central authority was transferred to the other side of Mesopotamia, Antioch or elsewhere—a fateful move. It is improbable that cuneiform and the Babylonian language continued to be used in Mesopotamia during the Hellenistic period, as it did in Babylonia, where it was certainly written as late as the last century B.C., and may have been a learned language till the second Christian century. Unfortunately there are no native documents from the pre-Christian Hellenistic period. That the Hellenizing process went as far as it did in Syria is unlikely, and even there Aramaic remained the language of the people even in the towns (cf. Edessa). Still, Greek influence was considerable. This would be mainly in the towns, the growth of which was quite a feature of the Macedonian rule in Mesopotamia (Pliny, *vii*. 30, § 117). This is seen in the Greek names which now appear: such as Seleucia opposite Samosata, Apamea (= Bireik) opposite Zeugma, Hierapolis (= Membij), Europos, Nicatorios, Amphipolis (= Thapsacus, or near it), Niochphorium (er-Rakka), Zenodotium (stormed by Crassus), all on or by the Euphrates; Edessa (q.v.) on the upper waters of the Belikh, Laodiceia (q.v.) above the confluence of the Belikh with the Belikh). These are all in the Osroene district; but Nisibin became an Antioch, and as its district was known as Mygdonia (from Macedon) there were doubtless many other Greek settlements. To a less extent the same influences would be at work in towns called even by Western writers by their real names, such as Batnae, Carrhae (Charran), Rhesaina.

Mesopotamia naturally had its share of suffering in the struggles that disturbed the time, when Eumenes or Seleucus traversed it or wintered there. It was invaded and temporarily annexed in 245 by Ptolemy III. Egeretes in his rapid expedition to beyond the Tigris. When Molon revolted on the accession of the youthful Antiochus III. (224 B.C.) he entered Mesopotamia from the south. Antiochus skirted the northern highlands by way of Našibn. How far the natives of Mesopotamia shared the desire of the Greek settlers (Joseph. *Antiq. xiii*. 5, 11, § 184–185) to help Demetrius II. Nicator in checking the aggressions of the rising power of Parthia under Mithradates I. we do not know. It was in Mesopotamia that a large part of the army of Antiochus VII. Sidetes was destroyed in 130 B.C., and the Syrian kings did not again seriously attempt to assert their rule beyond the Euphrates. When Ptolemy III. invaded Syria that was Antiochus' way to the west, the Parthian action against himself, however, even Mesopotamia suffered from the plunderers (Joh. *Antioch., in Müller iv*. 561). The immigration of Arabs

1 Probably the latest cuneiform document of certain date is a contract of 68 B.C. (cf. *Klio*, vi. 223 n. 3).
3 See E. R. Bevan, *House of Seleucu*, i. 219–222, and references given there.
had resisted Rome; but Mesopotamia was overrun, Nisibis and Carrhae being taken (533). It was immediately, indeed, recovered by Alexander Severus, and retained, whatever was the precise success of the war; but Nisibis and Carrhae were retaken by the Persians in the reign of Maximin. Under Gordian III. in 242 Mesopotamia was entered by a great Roman army which recovered Carrhae and Nisibis, and defeated the Persians at Rhesaena; but when Gordian, after a difficult march down the Khabur, was murdered at Zaithe below Circumcellions, Philip the Arabian (244) made the best terms he could with Shapur I. Whatever they were, the Romans were not to have been really withdrawn. A rest for Mesopotamia seems to have followed; but in 258 Shapur, tempted by the troubles in the Roman empire, overran the country taking Nisibis and Carrhae, and investing Edessa, and when Valerian invaded Mesopotamia he was eventually made prisoner, by Edessa (260). After Shapur’s cruel victories in Syria, however, he was defeated by Odaenathus, who relieved Edessa, and Mesopotamia became for ten years practically part of an Arabian Empire (see PALMYRA), as it was to be four centuries later. In consequence of the revolt of Zenobia, Mesopotamia was lost to the Christians and the Euphrates was the frontier. Aurelian overthrew the Palmyran rule; but he was assassinated before he could carry out his intended expedition against Persia, Probus was assassinated before he was able to do anything (or much), and although Carus easily overran Mesopotamia, which became Roman again, and even took Ctesiphon, the Romans retreated on his death (283–4). The next incident is the defeat of Galerius, between Carrhae and Callinicus, where he had entered Mesopotamia (about 306), in the war provoked by Nares in consequence of his relations with Armenia. When it was retrieved by a signal victory, Diocletian advanced to Nisibis and Thapsacus and then dictated terms of peace by which Mesopotamia to the Tigris was definitely ceded to Rome (298).

One result of the connexion with Rome was, naturally, that Mesopotamia came within the range of the Decian, and later the Diocletian persecutions (see EDESSA: § Sassanian Period). At the Nicene Council there were bishops from Nisibis (Jacob), Rhesaena, Macedonopolis (on the Euphrates, west of Edessa), and Persia (Harnack, Mission and Expansion of Christianity, ii. 146; see generally 142–152). After a forty years’ peace the struggle was resumed by Shapur II. Nisibis thrice endured unsuccessful siege (338, 346, 350), although meanwhile Constantine had suffered defeat at Singara (348). Then Mesopotamia enjoyed two short rests (separated by a sharp struggle) while the rivals were engaged elsewhere, when in 363 Julian (q.v.) made his disastrous attempt, and Jovian bought peace at the price, among other things, of Singara and Nisibis—i.e. practically all eastern Mesopotamia. The surrender of Nisibis, which had been in the possession of Rome for so many generations, caused consternation among the Christians, and Ephraem (q.v.) moved to Edessa, where his “school of the Persians” soon became famous (see EDESSA), and in the war of 421, in which the north-east of Mesopotamia was chiefly concerned, the Romans failed to take Nisibis, and it became a natural rallying point for the Nestorians after the decision of Ephesus (431). Matters were still more complicated when the Western Christians of Edessa found themselves unable to accept the ruling of Chalcedon against Monophysitism in 431 (see MONOPHYSITES), and there came to be three parties: Nestorians (q.v.), Jacobites (see JACOBITE CHURCH) and Melchites (q.v.).

In the beginning of the 6th century there was another severe struggle in Mesopotamia, which found an anonymous Syriac historian (see EDESSA), and in confirmation of agreement the Romans strongly fortified Daseh against Nisibis. The Persian invasion of Syria under Kavadh I. (q.v.) was driven back by Belisarius; but the latter was defeated in his pursuit at Rakka (531). The peace begun by Chosroes I. (532) was not long kept, and Roman Mesopotamia, except the pagan Harran, suffered severely (540), Edessa undergoing a trying siege (544). The fifty years’ peace also (562) was short lived; the Romans again failed in an attempt to recover Nisibis (573), whilst Chosroes’ siege of Dara was successful. Mesopotamia naturally suffered during the time of confusion that preceded and followed the accession of Chosroes II., and the Romans recovered their old frontier (591).

With the accession of Phocas (602) began the great war which shook the two kingdoms. The loss of Edessa, where Narses revolted, was temporary; but the Roman fortress of Dara fell after nine months’ siege (c. 605); Harran, Rass al-Ain and Edessa followed in 607, many of the Christian inhabitants being transplanted to the Far East, and Chosroes carried the victorious arms of Persia far into the Roman Empire. Finally, Heraclius, after capitulating the tide, and Kavadh II. restored the conquests of his predecessor. The Syrian Christians, however, found that they had only exchanged the domination of a Zoroastrian monarch for an unsympathetic ecclesiastical despotism. In the confusion that followed, when men of letters had to live and work in exile, Nisibis set up for a time (631–632) a grandson of Chosroes II. Finally all agreed on Yazdegerd III.; but, while Chosroes II. and Heraclius had been at death grips with each other a great interest had been growing in Arabia.

The Arab tribes in Mesopotamia were Christian, and Heraclius at Edessa hoped for their support; but Karkisiat and Hit succumbed (636), and then Tekrit; and Heraclius retired to Samosata. When in 638 he made another attempt, it is said at the entreaty of the Mesopotamian Christians, Arab forces appeared before Rakka, Edessa, Naṣībīn and other places, and all Mesopotamia was soon in the hands of the Arabs. Henceforth it looked to Damascus and to Kūfa and Baṣra, instead of to Constantinople or Ctesiphon. The new régime brought welcome relief to the Christian part of the population, for the Arabs took no note of their orthodoxies or heterodoxies. (Moawiya is said to have rebuilt the dome of the great church at Edessa after an earthquake in 678.) Fortunately for Mesopotamia the seats of the factions which immediately broke the peace of Islam were elsewhere; but it could not escape the fate of its geographical position.

The men of Raḵa were compelled to help Ali, after his march across Mesopotamia from near Māsūl, in getting a bridge made at Raḵa to convey his men to Šīffin. Not long afterwards there was a new excitement in Moawiya’s incursion across the Tigris. The discontent under Yazid III. was keen in Mesopotamia, where Merwān in fact got a footing, and when the troubles increased after his death he abandoned Damascus in favour of his son at Harran. His son was besieged by Daḵāḏ and his Khāriji and Saﬀarids in Naṣībīn; but a fierce battle at Mārdīn ended in Merwān’s favour (745). The cruelties that accompanied the overrunning of the Onanūvāv dynasty excited a revolt, which spread to Mesopotamia, and Harran had to undergo a siege by one of Merwān’s generals. It was next besieged by al-Maṭsūr’s brother; but the battle between the brothers was fought at al-Ṭūṣ. It was decisive, but there were further risings, involving Mesopotamia.1

An inevitable effect of the reign of Īlām had been that the kindred language of the Arabs gradually killed the vernacular Syriac of Mesopotamia (see EDESSA) as the alien Greek and Persian still had shown no tendency to do, and the classical period (4th to 8th centuries) of the only Mesopotamian literature we know, such as it is, useful but uninviting, came to an end (see SYRIAC LITERATURE). This naturally encouraged grammatical among the Moslem speakers the people the revolution which displaced the Arabian court of Damascus in favour of a cosmopolitan world centre at the Babylonian seat of the civilizations dealt with in the preceding paragraphs naturally gave an impulse to the wider scholarship. Translations were made from Greek, as, e.g. by Thābit b. Qurra of Ḫarrān (d. 901), and from Pahlavi.

Maṭsūr built a castle at Raḵa opposite Raḵa to control the country round, and his son Ḫārūn al-Rashid actually resided most of his reign, not at Bagdad but at Raḵa, where two generations later al-Battānī of Ḫarrān was making the astronomical observations on which his tables were based (see Table). Also in his bishopric of Nisibis, between the reigns of the caliph Maṭmīn, who was one of the earlier Arabaean Christians to use Arabic, has been thought to have contributed to the influences

1For this and following section see further CALIPHATE and PERSIA: History.
that developed the Mutattalite (Mutattalite) sect. Nasîbîn was the scene of another revolt (793) under a Khâritje leader. Hârun’s son Motaşim displeased the people by creating a bodyguard of Turks, and therefore transferred his seat to Sîmarrâ. This put the caliphate in a state of flux. Mesopotamia fell partly under the power of Ahmad ibn Tûlûn of Egypt and his son; but before the end of the 9th century the line of Hamdâdân, descendants of the Arab tribes, were the rulers of Mosul and in 919 one of them was governor of Dâr Râbî‘a. Later the brothers Nâsîr ad-Daula and Saif ad-Daula ruled over Mesopotamia and North Syria respectively. Mean­while the Câhidje Mûsûl, Nasîf, Râkka (944). The Hamdâdân were followed by the Yâqûtids, who had their seats at various places, such as Mûsûl, Nasîf, Râkka, Harrân, between 996 and 1005. The Yâqûtids had been defeated and taken under Muslim domination. They arrived at Jerusalem in 1076, the first crusaders reached Asia in 1097, and Bût Aulinî became the countship of Edessa (q.q.v.). The power of the Yâqûtids quickly disintegrated.

The off­spring of the third Seljûk Sultan, Zangi, governor of Írâq, made himself gradually (Mûsûl, Sinjâr, Jezîra, Harrân) master of Mesopotamia (1128), capturing Edessa in 1144. Mesopotamia fell to one of his sons, Saif ad-Din, and branches sprang up at Sinjâr and Jezîra.

To the same period belong other Írâbî dynasties; Bêtigçûnids at Harrân, Tekrît, â.; Orcotkîds at Edessa, Aná, â.; with Mârdîn as their headquarters. By 1185-1186 Salah ad-Dîn had made himself master of all the Írâbîhî dominions, and what the XVIIIth and XIXth Egyptian dynasties had attempted in vain. Mesopotamia remained in the hands of the Ayûbîbî family till the appearance of the Mongol invader in the 13th century. The terrible attack fell, however, on the rich province of Írâq and on the fertile provinces of Syria and Asia Minor. By a fortunate coincidence the invading Mongols were driven from Írâq by the Seljûk governor of Harrân. In 1260 the Mongols were followed by the Kârâkkûnûn. In 1502 Mesopotamia passed for a time into the hands of the Şâfîwî shah, Ishallâm; but in 1516 it came under the Osmânî Turks, to whom it has always belonged. The inland of the Persians in the 17th century was confined to the south.

Since Mesopotamia finally came into the power of the Osmânî sultans considerable changes in the population have occurred. About that time parts of a confederation of tribes which had taken the name of Shammar from a mountain in their neighbourhood, moved northwards from Central Armenia in search of better pasture, â.; successfully displacing their forerunners, they made themselves at home in the Syrian steppe—until their possession of it was in turn exceeded by the power of the Osmânî Aramî, for whom they finally made room by moving on into Mesopotamia, over which they spread, driving before them their predecessors the Tai (whose name the Mesopotamian Aramãcans had adopted as a designation for Arab in general), partly north of the Sinjâr, partly over the Tigris. Others they forced to abandon the nomadic life, and settle by the Khâbir (e.g. the Jebur) or the Euphrates. These adjustments, it is supposed, had been effected by 1700.

In 1831 'Âli, a newly appointed Turkish governor of Bagûd, induced Sûfîq, the chief of the Jerûb, the more important division of the Sinjâr, to come to him voluntarily, and for the sake of his wealth, who would not vacate his position, but then refused them the promised payment. To defend himself from the enraged Shammar 'Âli took refuge with the Yâqûtids. While the latter were busy elsewhere, he also succeeded in detaching part of the Shammar under Shûslî, who told the ‘Anâza he no longer needed their help. In the futile attempt of the three parties to dissolve the ‘Anâza Shûslî lost his life, but with the help of the Zûbeid the other two succeeded, and Sûfîq was now supreme. “King of the Steppe,” levying blackmail as he pleased. Other methods of disposing of him having failed, the Forte made his nephew a rival and made him fall a victim. By a strange fate the same fate he himself attended the hands of the pasha, but has since become a hero. Two of his sons became involved in a quarrel with the government, in consequence of which four households of Sinjâr was in turn plundered. One of them fell to death in 1658, and Fërbân, the eldest son, a peaceable man who had been made pasha, became supreme. One of Sûfîq’s widows had fled to her Tai kindred in Central Arabia with her youngest son Fërbân; but when he grew up she brought him back in the seventhties, and he immediately attracted a great following. He kept to the far north of Mesopotamia to avoid his brother Fërbân; but finally half­sedentary tribes on the Khâbir and the Bîlîk became tributary to him, and a more or less active warfare sprang up between the brothers, which ended in a partition of Mesopotamia.

Ferhân and the South Shammar claimed the steppe south­east of a line from Mûsûl to Mayûdîn (just below Karîsîb), and Färsûn the North Shammar on the north­west. Since Ferhân’s death the Porte has favoured one after another of his many sons, hoping to keep the South Shammar disunited, especially as they are more than the others. The Shammar have been in undisputed mastery from Urfa to the neighbourhood of Bagûd, practically all tribes paying kharwâwa to them, and even the towns, till the government garrisoned them. Some 60 of these more or less nomadic communities, of one or two thousand tents (or houses) each, representing a population of several hundred thousands are described by Oppenheim. Each has its recognized camp, and is headed by a chief. Most of them are Arab and Mahomedan. Some are Christian and some are not Arab: viz. Kurds, Turkomans or Circassians. For some years the Porte has been applying steady pressure on the nomads to induce them to settle, by increasing the number of military posts, by introducing Circassian colonies, as at Ras al­Aîn, sometimes by forcible settlement. More land is thus being brought under cultivation, the disturbing elements are being slowly brought under control, and life and property are becoming more secure.

Security is what the Porte chiefly needs. Hence its primary interest in introducing a railway scheme, with a view to agricultural development and perhaps the growth of cotton; Sir W. Willcocks’ irrigation schemes had not up to 1910 affected “Mesopotamia” directly. Apparently the real problem is one of population adequate to effect the improvements demanded. The new régime introduced in 1908 seems to justify a hopeful attitude. Apart from the disturbing effects of recent events in Persia, an exposition of present conditions would show progress. Exact statistics are not available because the vilayet of Mûsûl (35,150 sq. m., 351,000 pop.) takes in all that is beyond the borders of the Western Bank of the Euphrates.

Present Time.

Authority—Land and People; full references to Greek, Latin, Arabic and other writers are given in Ritter, Erdkunde x. 6-284, 921-1149; xi. 247-510, 660-726; for the conditions since the Arab conquest, Guy le Strange, Lands of the Eastern Caliphate (1903), chiefly pp. 86-114, is especially useful. Of recent works the following are valuable: E. Sachau, Reise in Syrien u. Mesopotamien (1883); M. v. Oppenheim, Von Mittelmee zum Persischen Golf, vol. ii. (1889). We may mention further: G. Hogarth, The Nearest East (1902), “Zur historischen Geographie des mesopotamischen Parallelogramms” (Sarg district), in Klio, I. 443-476; M. Sykes, “Journeys in North Mesopotamia” in Geog. Journal, vol. iv. 254-289; Euphrates and Jazira, op. cit., XXXIV. 61-65 (plans of two castles); D. Fraser, Short Cut to India (1909); W. Kurz, “Beurteilung der Aussichten auf eine Wiedereinbeziehung der Kultur der Euphrat- und Tigislandkultur, in Deutsche geographische Blatter, xxxi. 147-170 (1908); E. Pearse, “The Baghdad Railway,” in Contemp. Rev., 1906, 570-591; K. Baedeker, Palestine and Syria (1906), pp. 389-421. The annual report of the British Government on Mesopotamia are those for Aleppo, Mûsûl, Bagûdâl and Basra.

Maps.—The following deserve special mention: v. Oppenheim, op. cit., a most valuable large scale folding map in pockets of volumes; and Allen in Am. Anthro. 1901, 25-284, and in the Der alte Orient series (see an account and illustration) in the “Western Bank of the Euphrates”. On Mesopotamia for Aleppo, Mûsûl, Bagûdâl and Basra.

MEOXOLIC ACID—MESOZOA

The central cell is formed by the layer of the first two blastomeres, and remains quiescent until surrounded by the micromeres or products of division of the smaller blastomere. It then divides in two. The central cell is produced from the two small cells now called "primary germ cells," and they enter into and lie inside the large central cell. The primary germ cells divide until they have eight of them all lying within the axial cell. At this stage the future of the parasitic may take one of two directions. Following one path, the animal (now called a "Nematogen") arises by the segmentation of its primary germ cells to form infusorm larvae which, though smaller, are not really the parent form. Following the other path, the animal (now termed a "Rhombogen") gives rise to a number of infusiform larvae, several of these arising from each primary germ-cell. The infusiform larvae leave their Nematogen parent and swimming through the renal fluid attach themselves to the renal cells. They never leave their host, and die in sea-water. The infusiform larvae have a very complicated structure; they have six rows of ciliated cells; here as in the male the second ring of larvae can live in sea-water. They possibly serve to infect new hosts. Some authorities look upon these infusiform larvae as males, and consider that they fertilize some of the Nematogens,

which then give rise to males again, whereas the females which produce the vermiform embryos arise from unfertilized vermiform larvae. After the infusiform larvae have left the parent body, the Rhombogen takes to producing vermiform offspring, and thus becomes a secondary Nematogen. Thus, if the above views are correct, a Rhombogen is a protandrous hemaphrodite.

E. Neresheimer has recently described under the name of Leohnanella catenata an organism parasitic in Fritillaria which shows marked affinities with the Rhombozoa. The genus Hoplozoos of which two species have been found in the worms Trichina and Dugel is also placed in this group.

Class II. ORTHONECIDA (A. Giard.).—The Orthonectida contain animals with a central mass of eggs destined to form male and female reproductive cells surrounded by a single layer of ciliated ectoderm cells arranged in regular rings which contain varying numbers of rows of cells. Muscular fibrils occur between the outer and inner cells. The sexes are separate and unlike, and there are two kinds of females, cylindrical and flat. There are but two genera, Rhopalura and Stacochirus, the latter found in a Polychaeta. The male R. giardi lives in the body-cavity of Amphipora squamata, has six rings of ectodermal cells all ciliated except the second, whose cells contain refringent granules. The ectoderm encloses the testis, a mass of cells which have arisen from a single axial cell in the embryo. The female differs from the male in appearance, and in size it is larger. It occurs in two forms: (1) The cylindrical with 8 (or 9) rows of ectoderm cells; the second ring is devoid of cilia. (2) The flat females are broader, uniformly ciliated, and have not rings of ectoderm cells. The central mass of cells forms

on slender cylindrical spikes from 1½ to 4 in. long; the long narrow seeds are constricted between the seeds, of which they are contained from ten to thirty surrounded by a thick spongy layer of sweet pulp. The wood is hard, heavy, and close-grained, but not very strong; it is almost indestructible in contact with soil, and is largely used for fence-posts and railway ties. The ripe pods supply the Mexicans and Indians with a nutritious food; and a gum resembling gum arabic exudes from the stem.

An allied species *Prosopis pubescens*, a small tree or tall shrub, native of the arid regions of the south-western United States, is known as the screw-bean or screw-pod mesquite from the fact that the pods are inserted into the stem in a spiral-like manner; they are used as fodder, and are sweet and nutritious, but smaller and less valuable than those of the mesquite.

For a fuller account of these trees see Charles Sprague Sargent, *Silva of North America*, iii, p. 99 (1892).

**MESS (an adaptation of O. Fr. mes, mod. mes; Ital. messo; derived from the Late Lat. missum, past participle of mittere "to send or place in position"), a service of meat, a dish sent to table. The term is also used of the persons who are in the habit of eating their meals together, and thus particularly of the parties into which a ship's company or a regiment is divided, either at meals or in the course of a journey. Originally, a mess in this sense was a group of four persons sitting at one table and helped from the same dishes. In the Inns of Court, London, the original number is preserved, four bachelors or four students dining together.

In early times the word mess was applied to food of a more or less liquid character, as soup, porridge, broth, &c. It is probably in allusion to the sloppy nature of semi-liquid messes of food that a mess has come also to mean a state of disorder, confusion and discomfort. "Sweat takes the word in this sense to be a variant of "mash," originally to mix up.

**MESSAGE** (a word occurring in slightly different forms in several languages, e.g. Fr. message, Span. mensaje, It. messaggio; adapted from the Low Lat. missicum, from mittere), a communication either verbal, written or printed, sent from one person to another. Message is the term generally applied to the official communications addressed by the heads of states to their legislatures at the opening of the session or at other times. These also, though written, are borne and delivered by special messengers and have the force of a face to face speech. The sessional and other messages to Congress of the president of the United States are printed and are the proceedings of the Congress.

Washington and John Adams delivered them in person but the practice was discontinued by Jefferson. "Messinger" is of the same derivation; the earlier form of the word was mesager (cf. passenger, scavenger). In ordinary language the word means one who is charged with the delivery of a message. In Scottish law a messenger-at-arms is an official appointed by Lyon-King-at-Arms to execute summonses and letters of diligence connected with the Court of Sessions and Court of Justiciary (see Wrtr: § Scotland). Technically the term "messenger" is given to an endless rope or chain, passing from the capstan to the cable so that the latter may be hauled in when the messenger is wound round the capstan; also to a similar contrivance for hauling in a dredge.

**MESSAGER, ANDRE CHARLES PROSPER (1853-1940)**, French musician, was born at Montluçon on the 30th of December 1853; he studied at Paris, and in 1874 became organist at St Sulpice. He was for some time a pupil of Saint-Saëns. In 1876 he won the gold medal of the Société des Compositeurs with a symphony. In 1886 he was appointed music director at the Opéra-comique. In 1887 he completed the Pirmion Bernicat's comic opera *Francois des bas bleus*; and in 1885 produced his own operettas, *La Fauvette du temple* and *La Borénaize*, the latter being performed in London in 1886. His ballet *Les Deux pigeons* was produced at the Paris Opéra in 1886. But it was the production of his comic opera *La Bascule* in 1890 at the Opéra Comique (English version in London the following year) that established his reputation; and subsequently this was increased by such tuneful and tasteful light
MESSALLA CORVINUS—MESSAPII

opera as Madame Chrysthèlème (1803). Miret (1804), Les Petites Michus (1857), and Véronique (1858), the latter of which had a great success in London. Roman families, writing for some years at the Opéra Comique in Paris, Messager's services were also secured in London in 1901 and later years as one of the directors of the Covent Garden opera.

MESSALLA CORVINUS, MARCUS VALERIUS (65 B.C.—A.D. 8), Roman general, author and patron of literature and art. He was educated partly at Athens, together with Horace and the younger Cicero. In early life he became attached to republican principles, which he never abandoned, although he avoided offending Augustus by too open an expression of them. He maintained that the establishment of freedmen should be bestowed upon Augustus, and yet resigned the appointment of prefect of the city after six days' tenure of office, because it was opposed to his ideas of constitutionalism. In 43 B.C. he was proscribed, but managed to escape to the camp of Brutus and Cassius. After the battle of Philippi (42) he went over to Antony, but subsequently transferred his support to Octavian. In 31 Messalla was appointed consul in place of Antony, and took part in the battle of Actium. He subsequently held commands in the East, and suppressed the revolted Aquitanians; for this latter service a triumph was decreed to him. Messalla restored the road between Tusculum and Alba, and many handsome buildings were due to his initiative. His influence on literature, which he encouraged after the manner of Maecenas, was considerable, and the group of literary persons whom he gathered round him—including Tibullus, Lygdamis and the poet Sulpicia—has been called "the Messalla circle." With Horace and Tibullus he was on intimate terms, and Ovid expresses his gratitude to him as the first to notice and encourage his work. The two paeans by unknown authors (one printed among the poems of Tibullus as iv. 1, the other included in the Calamption, the collection of small poems attributed to Virgil) indicate the esteem in which he was held. Messalla was himself the author of various works, all of which are lost. They included Memoirs of the civil wars after the death of Caesar, used by Suetonius and Plutarch; b lyric poems in Greek; translations of Greek speeches; occasional satirical and erotic verses; essays on the minutiae of grammar. As an orator, he followed Cicero instead of the Atticizing school, but his style was affected and artificial. Later critics considered him superior to Cicero, and Tiberius adopted him as a model. Late in life he was accused of trying to place his son, Messalla the Younger, who had been identified with an extinct poem De propegeni Augusti Caesaris bearing the name of Messalla, but really a 13th-century production.

Monographs by L. Wiese (Berlin, 1826), J. M. Valon (Groningen, 1874), L. Fontaine (Versailles, 1878); H. Schulz, De M. V. oetate (1886); "Messalla in Aquitania" by J. P. Postgate in Classical Review, March 1905; W. Y. Sellars, Roman Poets of the Augustan Age, Horace and the Odege Poets (Oxford, 1892), pp. 213 and 221 to 258; the spurious poem ed. by R. Mecenate (1820).

Two other members of this distinguished family of the Valerian gens may be mentioned:

1. M Anius Valerius Messala, father of the preceding, consul in 53 B.C. He was twice accused of illegal practices in connection with the elections; on the first occasion he was acquitted on the ground of obvious guilt, through the eloquence of his uncle Quintus Hortensius; on the second he was condemned. He took the side of Caesar in the civil war. Nothing appears to be known of his latter history. He was an able writer for fifty-five years and wrote a work on the science of divination.

Cicero, Ad Fam. vi. 18, viii. 4, ad Atticum, iv. 16; Dio Cassius xii. 17, 45; Bellum africanum, 28; Macrobius, Saturnalia, 9, 14; Augustine, Ep. xliii. 8.

2. Manius Valerius Maximus Corvinus Messalla, consul 263 B.C. In this year, with his colleague Manius Oatciulus (or Octacilcius) Crassus, he gained a brilliant victory over the Carthaginians and Syracusians; the honour of a triumph was decreed to him alone. His relief of Messana obtained him the cognomen Messalla, which remained in the family for nearly 800 years. To commemorate his Sicilian victory, he caused it to be pictorially represented on the wall of the Curia Hostilia, the first example of an historical fresco at Rome. He is said also to have brought the first sun-dial from Catana to Rome, where it was set up in the Forum.

Polybius i. 16; Diod. Sic. xxii. 4; Zonaras viii. 9; Pliny, Nat. Hist. vii. 60, xxxv. 4 (7).

MESSALLINA, VALERIA, the third wife of the Roman emperor Claudius (g.n.). She was notorious for her profligacy, avarice and ambition, and exercised a complete ascendancy over her weak-minded husband, with the help of his all-powerful freedmen. During the absence of Claudius from the city, Messallina forced a handsome youth named Gaius Silius to divorce his wife and go through a regular form of marriage with the emperor. The freedman was warned by the fate of another freedman Polybius, who had been put to death by Messallina, informed Claudius of what had taken place, and persuaded him to consent to the removal of his wife. She was executed in the gardens of Lucullus, which she had obtained on the death of Valerius Asiaticus, who through her machinations had been condemned on a charge of treason. She was only twenty-six years of age. By Claudius she was the mother of the unfortunate Britannicus, and of Octavia, wife of Nero.

See Tacitus, Annals, xi. 1–38; Dio. Cassius ix. 14–31; Juvenal vii. 99 (1850); xvii. 33; vi. 81; Suetonius, Claudius; Merivale, Hist. of the Romans under the Empire, ch. iv. 301; A. Stahr, "Agripina" in Bildcr aus dem Alterthume, iv. (1865).

MESSAPII, an ancient tribe which inhabited, in historical times, the south-eastern peninsula or "heel" of Italy, known variously in ancient times as Calabria, Messapia and Iapygia. Their chief towns were Uzentum, Rudiae, Brundisium and Uria. They are mentioned (Herod. vii. 170) as having inflicted a serious defeat on the Greeks of Tarentum in 473 B.C. Herodotus adds a tradition which links them to the Cretan subjects of "King Minos." Their language is preserved for us in a scatty group of inscriptions, of which only a few contain more than proper names, and in a few glosses in ancient writers collected by Mommsen (Unteritalische Dialekte, p. 70). Unluckily very few originals of the inscriptions are now in existence, though some few remain in the museum at Taranto. The only satisfactory transcripts are those given by (1) Mommsen (loc. cit.) and by (2) J. P. Droop in the Annual of the British School at Athens (1905—1906), xii. 137, who includes, for purposes of comparison, as the reader should be warned, some specimens of the unfortunately numerous class of forged inscriptions. A large number of the inscriptions collected by Mommsen in the appendices to Fabre's Corpus inscriptionum italicarum are forgeries, and the text of the rest is negligently reported. It is therefore safest to rely on the texts collected by Mommsen, cumbred though they are by the various readings given to him by various authorities. In spite, however, of these difficulties some facts of considerable importance have been established.

The inscriptions, so far as it is safe to judge from the copies of the older finds and from Droop's facsimiles of the newer, are all in the Tarentine-Italic alphabet (with [ for v and b for f]. For limits of date 400–150 B.C. may be regarded as approximately probable; the two most important inscriptions—those of Bindis and Vaste—may perhaps be assigned provisionally to the 3rd century B.C.

Mommsen's first attempt at dealing with the inscriptions and the language attained solid, if not very numerous, results, chief of which were the genitival character of the endings—addi and addi, and the conjunctival value of addi (loc. cit. 79–84 sqq.). Since that time (1850) very little progress has been made. There is, in fact, only one attempt known to the present writer to which the student can be referred as proceeding upon thoroughly scientific lines, that of Professor Alf Torp in Indogermanische Forschungen (1893), v., 195, which deals fully with the two inscriptions just mentioned, and practically sums up all that is either certain or probable in the conjectures of his predecessors. Hardly more than a few words can be said to have been separated and translated with certainty—kalatara (masc. gen. sing.) "of a herald" (written upon a herald's staff which was once in the Naples Museum); aran (acc. sing. fem.) "arable
Messenia—Messenia

land”; mazes, “greater” (neut. acc. sing.), the first two syllables of the Latin maioris; while tēpis (3rd sing. aorist indic.) “placed” or “offered” and forms corresponding to the article (Pé = Greek το) seem also reasonably probable.

Some phonetic characteristics of the dialect may be regarded as quite certain; (1) the change of the original short δ to θ (as in the last syllable of the genitive kalothoros); (2) of final -m to -n (as in aran); (3) of -νι-τι-σι respectively to -νι-θι-σι and -σι as in dazônν “Daráni,” darânikì “Dáron”; dazthès, gen. dazsthi “Dazethius, Dazeth,” from the shorter stem dazet-; Vallasso for Vallasteo (a derivative from the shorter name Valla); (4) the loss of final ῦ (as in tēpis), and probably of final ι (as in des, perhaps meaning “set” or “set forth”) of Gr. tēpis “set forth” by the change of final dh to θ (anda = Gr. θάνατον θῆκον); (5) the loss of the diphthong θε̆- (beran = Lat. férant); (6) -αῠ- before (at least some) consonants becomes -α (Basta, earlier Basta), (7) Very great interest attaches to the form penkâhë—which Torp very probably identifies with the Oscan stem pompaio—which is a derivative of the Indo-European numeral *penque “5”.

If this last identification be correct it would show that in Messenian just as in Venetic and Ligurian the original velars were retained as gutturals and not converted into labials. The change of the short θ to η (as in tēpis) has probably been going on for a considerable time and is well recorded with the northern races of Indo-European such as Gothic, Albanian and Lithuanian, and not appearing in any other southern dialect hitherto known. The Greek Αφριδία appears in the form Aprodita (dat. sing., fem.). The use of double consonants which has been already pointed out in the Messenian inscriptions has been very acutely connected by Deecke with the tradition that the same practice was introduced at Rome by the poet Ennius who came from the Messenian town of Rutiae (Festus, p. 293 M).

It should be added that the proper names in the inscriptions show the regular Italic system of gentile names preceded by a personal praenomen; and that some inscriptions show the interesting feature which appears in the Tables of Heraclea of a crest or coat of arms, such as a triangle or an anchor, peculiar to particular families. The same reappears in the Ioviae (q.v.) of Capua and Cumae.

For further information the student must be referred to the sources already mentioned and further to W. Deecke in a series of articles in the Rheinisches Museum, xxxiv. 370 sqq.; xxxv. 373 sqq.; xl. 131 sqq.; xlii. 226 sqq.; S. Bugge, Bessemergeth Beiträge, vol. 18. A newly discovered inscription has been published by L. Cenci Normanni, Atti dell’Accad. Naz. dei Lincei (cl. 86); and one other by Professor Viola, ibid. 1884, p. 128 sqq. and in Giornale degli Scavi di Pompei, vol. 4 (1879), pp. 70 sqq. The place-names of the district are collected by R. S. Conway, The Italic Dialects, p. 31; for the whole of Messenia see ibid. gr. tâbôm.

For a discussion of the important ethnological question of the origin of the Messenians see W. Helbig, Hermes, xii. 257; P. Krenschmer, Einleitung in die Geschichte der griechischen Sprache, pp. 262 sqq., 272 sqq.; H. Hirt, Die sprachliche Stellung der Ilirischen (Pestchrift für H. Kiepert, pp. 179-188). Reference should also be made to the discussion of their relation to the Veneti by C. Paul in Die Venerit, p. 431 sqq., especially p. 437; and also to R. S. Conway, Italic Dialects, 1. 15. (R. S. C.)

Messenia, an ancient Greek city, the capital of Messenia, founded by Epaminondas in 362 B.C., after the battle of Leuctra and the first Theban invasion of the Peloponnesus. The town was built by the combined Theban and Argive armies and the exiled Messenians who had been invited to return and found a state which should be independent of Spartan rule. The site was chosen by Epaminondas and lay on the western slope of the mountain which dominates the Messenian plain and culminates in the two peaks of Ithome and Eua. The former of these is the acropolis of the capital. The city occupied the same system of fortifications as the lower city. Messene remained a place of some importance under the Romans, but we hear nothing of it in medieval times and now the hamlet of Mamvromati occupies a small part of the site.

Pausanias has left us a description of the city (iv. 31-33), its chief temples and statues, its springs, its market-place and gymnasium, its place of sacrifice (leopoliois), the tomb of the hero Aristomenes (q.v.) and the temple of Zeus Ithomatas on the summit of the acropolis with a statue by the famous Argive sculptor Ageladas, originally made for the Messenian helots who had settled at Naupactum at the close of the third Messenian War. But what chiefly excited his wonder was the strength of its fortifications, which excelled all those of the Greek world. Of the wall, some 35 m. in extent, considerable portions yet remain, especially on the north and north-west, and almost the entire circuit can still be traced, affording the finest extant example of Greek fortification. The wall is flanked by towers about 31 ft. high set at irregular intervals: these have two storeys with loopholes in the lower and windows in the upper, and are entered by doors on a level with the top of the wall which is now 20 ft. The Messenian gateway on the south can be located, the eastern or Laccanian, situated on the eastern side of the saddle unifying Ithome and Eua, and the northern or Arcadian gate. Of the former but little remains: the latter, however, is excellently preserved and consists of a circular court about 20 yds. in diameter with inner and outer gates, the latter flanked by square towers some 11 yds. apart. The lintel of the inner gate was formed by a single stone 18 ft. 8 in. in length, and the masonry of the circular court is of astonishing beauty and accuracy. The other buildings which occupied the acropolis included a temple of Athena, the Acropolis chamber or Bouleuterion, and the propylaeum of the market, while on the shoulder of the mountain are the foundations of a small temple, probably that of Artemis Laphria.

MESSENA (Gr. Μεσσηνία or Μεσσηώνια), the S.W. district of the Peloponnesus, bounded on the E. by Mt Tságyétos, on the N. by the river Neda and the Arcadian Mountains, on the S. and W. by the sea. Its area is some 825,000 acres, considerably less than that of Shropshire or Wiltshire. Historically and economically its most important part is the great plain, consisting of two distinct portions, watered by the river Panisus (mod. Pírnata) and its affluents. This is the most fertile tract in Greece, and at the present day produces oranges, citrons, almonds, figs, grapes and other fruits in great abundance and of excellent quality. The plain is bounded on the north by the Nomian Mountains (mod. Tetrási, 3670 ft.) and their westerly prolongations, and on the S.W. by the hills of Cypriasia (4000 ft.), a southern continuation of which forms the eastern side of the Morea, attaining its greatest height in Mt Mathia (mod. Lykkídímo 3160 ft.). Off the south coast of this peninsula lie the three Oenussae islands and the islet of Thegannusa (Venetikó). In spite of its long coast-line, Messenia has no good harbours except the Bay of Pylos (Navarino), and has never played an important part in Greek naval history.

The earliest inhabitants of Messenia are said to have been Pelasgians and Leleges (q.v.), of whom the latter had their capital the Peloponnesus. Then came an Aescol-Minian immigration, which apparently extended to Messenia and the Peloponnesus. Nestor almost certainly lay in Triphyla, and not at the site which in historic times bore that name. In the Homeric poems eastern Messenia is represented as under the rule of Menelaus of Sparta, while the western coast is under the Neleids of Pylos, but after Menelaus’ death the Messenian frontier was pushed eastwards as far as Tságyétos. A body of Doriens under Cresphontes invaded the country from Arcadia, and, taking as their capital Stényclus in the northern plain, extended their suzerainty and then their rule over the whole district. The task apparently proved an easy one, and the Doriens blending with the previous inhabitants produced a single Messenian race with a strong national feeling. But the fertility of the soil, the warm and genial climate, the mingling of races and the absence of opposition, combined to render the Messenians no match for their hardy and warlike neighbours of Sparta. War broke out—in consequence, it was said, of the murder of the Spartan king Teleclus by the Messenians—which, in spite of
the heroism of King Euphrates and his successor Aristodemus (q.v.) finished in the subjection of Messenia to Sparta (c. 720 B.C.). Two generations later the Messenians revolted and under the leadership of Aristomenes (q.v.) kept the Spartans at bay for some seventeen years (648–631 B.C., according to Grote): but the stronghold of Ira (Eira) fell after a siege of eleven years, and those Messenians who did not leave the country were reduced to the condition of helots. The next revolt broke out in 464, when a severe earthquake destroyed Sparta and caused great loss of life: the Spartans entrenched themselves on some years on the rock-citadel of Ithome, as they had done in the first war; but eventually they had to leave the Peloponnesse and were settled by the Athenians at Naupactus in the territory of the Locri Ozoale. After the battle of Leuctra (371 B.C.) Epaminondas invited the exiled Messenians scattered in Italy, Sicily, Africa, and elsewhere to return to their country: the city of Messene (q.v.) was founded in 369 to be the capital of the country and, like Megalopolis in Arcadia, a powerful check on Sparta. Other towns too were founded or rebuilt at this time, though a great part of the land still remained very sparsely peopled though independent Messenia never became really powerful or able to stand without external support. After the fall of the Theban power, to which it had owed its foundation, it became an ally of Philip II. of Macedonia and took no part in the battle of Chaeronea (338 B.C.). Subsequently it joined the Achaean League, and we find Messenian troops fighting along with the Achaean and Antigonus Doson at Sellasia in 222 B.C. Philip V. sent Demetrius of Phars to seize Messene, but the attempt failed and cost the life of Demetrius: soon afterwards the Achaean League was formed, and it was in taking the city, but was forced to retire by the timely arrival of the Philopoemen and the Megalopolitans. A war afterwards broke out with the Achaean League, during which Philopoemen was captured and put to death by the Messenians (183 B.C.), but Lycoctas took the city in the following year, and it again joined the Achaean League, though much weakened by the loss of Abia, Thuria and Phrae, which broke loose from it and entered the League as independent members (see ACHAEO-AN LEAGUE). In 146 B.C. the Messenians, together with the other states of Greece, were brought directly under Roman sway by L. Mummius, who had just been appointed a praetor in Illyria (q.v.) and had, in taking the city, been made a senator. He then proceeded to settle at Sparta the Messenians who had been transported from Messinia to Sparta for the cultivation of the famous Ager Denilio. On the western slope of Taygetus: after various decisions by Philip of Macedon, Antigonus, Mummium, Caesar, Antony, Augustus and others, the question was settled in 40 B.C. by Tiberius and the Senate in favour of the Messenians (TAC. ANN. iv. 43). In the middle ages Messenia shared the fortunes of the rest of the Peloponnesus. It was over-run by Slavic hordes, who have left their traces in many village names, and was one of the chief battlefields of the various powers—Byzantines, Franks, Venetians and Turks—who struggled for the possession of the Morea. Stirring reminders of these conflicts are afforded by the extant ruins of the medieval strongholds of Kalamata, Coron (anc. Asine, mod. Korone), Modon (Meliton) and Pylos. At the present day Messenia forms a department with its capital at Kalamata; and a population numbering (according to the census of 1907) 127,991.

MESSIAH (Dan. x. 25, 26), and MESSIAS (John i. 41; iv. 25), translations (the first form modified by reference to the etymology) of the Greek ΜΙΣΣΗΑ (ΜΙΣΣΗΑ), which in turn represents the Aramaic מִשְׁמַע (nishmâh), answering to the Hebrew מִשְׁמַע, “the anointed.” 1 There can be no doubt that a magical power was ascribed to the anointing oil (cf. Frazer, Golden Bough, 2nd ed., ii. 364 sqq.). The king was thereby rendered sacrosanct (1 Sam. xxiv. 6 sqq.; 2 Sam. i. 14 sqq.; iv. 9 sqq.), and he was considered to be endowed with a special virtue. Thus whosoever curses the king is stoned as though God Himself had been cursed (2 Sam. xix. 22). In ancient Egyptian cults the priest, after he had solemnly saluted the gods, begins the daily toilet of the god, which consists in sprinkling his image, clothing it with coloured cloths, and anointing it with oil (Erman, Die aegyptische Religion, p. 49). In the magical texts of Babylonia a similar virtue was attached to oil: “bright oil, pure oil, resplendent oil that bestows magnificence on the Gods . . . the oil for the conjuration (līmu) of Marduk” (Talquist, Mabûl series, tablet vii. col. r, 31 sqq.; cf. Gressmann, Der Ursprung der israelitisch-jüdischen Eschatologie, p. 298, sqq.). We have, in Schrader’s X.I.B. v. letter 37 (p. 98), evidence from the Tell el-Amarna tablets that the anointing of kings was practiced in Egypt or Syria in 1450 B.C. (c.) in a letter addressed to the Egyptian king by Ramman-nirari of Nubha, expressing the intimate relation which in primitive times subsisted between the sorcerer and the king see the citation from Frazer’s Early History of KINGSHIP, p. 127, in the article FOREST, and cf. p. 20: “Classical evidence points to the conclusion that in prehistoric ages . . . the various tribes or cliques were ruled by kings who discharged priestly duties” (p. 31). Thus the early kings of Assyria were priests of Assur (Ass.), the tutelary deity of Assyria. Tigrath-Pileser I. (c. 1100 B.C.) calls his predecessors, Sundar and Hami-Dagan, Ἰακχου (ia-te-ti) of the God Assur (Prism-insc. col. vii. 62, 63). Later kings, e.g. Shalmaneser II. (Nimrud-obelisk, line 15, monolith, line 11) and Assur-bani-pal (Rammân cyl. col. vii. 94) call themselves by the more definite title of ʾašu of Assur. The Hebrew word with the article prefixed occurs in the Old Testament only in the phrase “the anointed priest” (Lev. iv. 3, 5, 16; vi. 22 [r.’]), but “Yahweh’s anointed” is a common title of the king of Israel, applied in the historical books to Saul and David, in Lam. iv. 20 to Zedekiah, and in Isa. xlv. 1 extended to Cyrus. In the Psalms corresponding phrases (My, Thy, His anointed) occur only in neighbor passages which may be added the lyrical passages 1 Sam. ii. 16, Hab. ii. 13.

In the present attitude of literary criticism it would be most difficult to assert, as Robertson Smith did in the 9th edition of this work, that “in the intention of the writers it [i.e. the term messiah or “anointed”] refers to the king then on the throne.” Nor would most recent critics agree with Professor Driver (LOT., 8th ed. p. 385) in considering Pss. ii. and lxxiv. as “presumably pre-exilic.” G. Buchanan Gray (J.Q.R., July 1895, p. 658 sqq.) draws a parallel between the “king” in the Psalms and the “servant” in Deutero-Isaiah or Yahweh’s “Son” (in Hos. xi. 1, &c.) which is applied to Israel either actual or idealized. It would be possible so to interpret “king” or “anointed” in some Psalms, e.g. lxi., lxxiii., and lxxiv., but hardly in Pss. ii., lxxiii. and lxxiv., where the Messianic reference is strongly personal. 2 In the Psalms the ideal aspect of the kingship, its religious importance as the expression and organ of Yahweh’s sovereignty, is prominent. When the Psalter became a liturgical book the historical kingship had gone by, and the idea alone remained, no longer as the interpretation of a present political fact but as part of Israel’s religious history. 3 It was impossible, however, to think that a true idea had become obsolete merely because it found no expression on earth for the time being; Israel looked again for an anointed king to whom the words of the sacred hymns should apply with a force

1 The transcription is as in Παλατίνης Περὶ τῆς Εὐνομίας, ed. Lag., pp. 247, 281. Bas. ii. 3. For the translation as for on, see Lagarde, Psalt. Memph., p. vii.

2 The plural is found in Ps. cxv. 15, of the patriarchs as consecrated persons.

3 In Ps. lxxix. 9 [10] it is disputed whether the anointed one is the king, the priest, or the nation as a whole. The second view is perhaps the best.
never realized in the imperfect kingship of the past. Thus the Psalms were necessarily viewed as prophetic; and meantime, in accordance with the common Hebrew representation of ideal things as existing in heaven, the true king remains hidden with God. The steps by which this result was reached must, however, be considered in detail.

The hope of the advent of an ideal king was only one feature of that larger hope of the salvation of Israel from all evils, which was constantly held forth by all the prophets, from the time when the seers of the 8th century B.C. proclaimed that the true conception of Yahweh's relation to His people could become a practical reality only through a great deliverance following a sifting judgment of the most terrible kind. The idea of a judgment so severe as to render possible an entire breach with the guilty past is common to all the prophets, but is expressed in a great variety of forms and images. As a rule the prophets directly connect the final restoration with the removal of the sins of their own age; to Isaiah the last troubles are those of Assyrian invasion, to Jeremiah the restoration follows on the exile to Babylon, to Daniel on the overthrow of the Greek monarchy. But all agree in giving the central place to the renewal of the decisive kingship of Yahweh. Of this conception the religious subject as the nation of Israel, with a national organization under Yahweh as king, is common to the whole Old Testament, and connects prophecy proper with the so-called Messianic psalms and similar passages which speak of the religious relations of the Hebrew commonwealth, the religious meaning of national institutions, and so necessarily contain ideal elements reaching beyond the empirical present. All such passages are frequently called Messianic; but the term is more properly reserved as the specific designation of one particular branch of the Hebrew hope of salvation, which became prominent in post-canonical Judaism used the name of the Messiah as a technical term (which it never is in the Old Testament), and exercised a great influence on New Testament thought—the term "the Christ" (ὁ χριστός) being itself nothing more than the translation of "the Messiah."

In the period of the Hebrew monarchy the thought that Yahweh is the divine king of Israel was associated with the conception that the human king reigns by right only if he reigns by commission or "unction" from Him. Such was the theory of the kingship in Ephraim as well as in Judah (Deut. xxxii.; 2 Kings ix. 6), till in the decadence of the northern state Amos (ix. 11) foretold the reintegration of the Davidic kingdom, and Hosea (iii. 5; viii. 4) expressly associated a similar prediction with the condemnation of the kingship of Ephraim as illegitimate. So the great Judaean prophets of the 8th century connect the salvation of Israel with the rise of a Davidic king, full of Yahweh's Spirit, in whom all the energies of Yahweh's transcendent kingship are as it were incarnate (Isa. ix. 6 seq.; xi. 1 seq.; Micah v.). This conception, however, is not one of the constant elements of prophecy; other prophecies of Isaiah look for the decisive interposition of Yahweh in the crisis of history without a kingly deliverer. Jeremiah again speaks of the future David or righteous sprout of David's stem (xxiii. 5 seq.; xxx. 9) and Ezekiel uses similar language (xxxiv., xxxvii.); but that such passages do not necessarily mean more than that the Davidic dynasty shall be continued in the time of restoration under worthy princes seems clear from the way in which Ezekiel speaks of the prince in chs. xlv., xlvii. And yet we have no fixed doctrine of a personal Messiah, but only material from which such a doctrine might be drawn. The religious view of the kingship is still essentially the same as in 2 Sam. vii., where the endless duration of the Davidic dynasty is set forth as part of Yahweh's plan.

There are other parts of the Old Testament—notably 1 Sam. viii., xii. (belonging to the later stratum)—in which the very existence of a human kingship is represented as a departure from the theocratic ideal, and after the exile, when the monarchy had come to an end, we find pictures of the latter days in which its restoration has no place. Such is the great prophecy of Isa. xl.-xlviii., in which Cyrus is the anointed of Yahweh. So too there is no allusion to a human kingship in Joel or in Malachi: the old forms of the Hebrew state were broken, and religions dressed themselves in other shapes. In the book of Daniel it is collective Israel that, under the symbol of a "son of man," receives the kingdom (vii. 15, 18, 22, 27).

Meantime, however, the decay and ultimate silence of the living prophetic word concurred with prolonged political servitude to produce an important change in Hebrew religion. To the prophets the kingship of Yahweh was not a mere ideal, but an actual reality. Its full manifestation indeed, to the eye of sense and to the unbelieving world, lay in the future; but true faith found a present shadow of the Messianic hope in the shape of providence and interpreted to each generation by the voice of the prophets. And, while Yahweh's kingship was a living and present fact, it refused to be formulated in fixed invariable shape.

But when the prophets were succeeded by the scribes, the interpreters of the written word, and the yoke of foreign oppressors rested on the land, Yahweh's kingship, which presupposed a living nation, found not even the most inadequate expression in daily political life. Yahweh was still the lawgiver of Israel, but His law was written in a book, and He was not present to help administer it. He was still the hope of Israel, but the hope too was only to be read in books, and these were interpreted of a future which was no longer the ideal development of forces already at work, but wholly new and supernatural. The present was a blank, in which religious duty was summed up in patient obedience to the law and penitent submission to the Divine chastisements. The scribes were mainly busied with the law; but no religion can subsist on mere law; and the systematization of the prophetic hopes, and of those more ideal parts of the other sacred literature which, because ideal and disavowed from the present, were now set on one line with the prophesies, went on side by side with the systematization of the law, by means of a harmonistic exegesis, which sought to gather up every prophetic image in one grand panorama of the issue of Israel's and the world's history. The beginnings of this process can probably be traced within the canon itself, in the book of Joel and the last chapters of Zechariah; and, if this be so, we see from Zech. ix. that the picture of the ideal king claimed a place in such constructions. The full development of the method belongs, however, to the post-canonical literature, and was naturally much less regular and rapid than the growth of the legal tradi-

1 Most recent critics regard Amos ix. 9-15 as a later addition, and the same view is held by Nowack, Harper and others respecting Hosea vii. 4. So they should treat the gradations in qualities from gundom (Isa. i. 1-7), xi. 1 seq. be held to be contemporary with Isa. iv. 3, 4, and to refer to Zerubbabel. Cf. Haggai ii. 21-22, composed seventeen years afterwards. Mic. v. 1-8 can with difficulty be regarded as genuine.

2 The hopes which Haggai and Zechariah connect with the name of Zerubbabel, a descendant of David, hardly form an exception to this statement. There may still be a reference to him in Isa. i. 3, 4.

MESSIAH

193

later Jewish doctrine of the last things and in the official exegesis of the Targums. In the very developed eschatology of Danieli they are, as we have seen, altogether wanting, and in the Apocrypha, both before and after the Maccabean revival, the everlasting throne of David’s house is a mere historical reminiscence (Ecclus. xlvii. 11; 1 Macc. ii. 57). So long as the wars of independence occupied the Palestinian Jews, and the Hasmonaean sovereignty promised a measure of independence and felicity under the law, the hope that connected itself with the House of David was not likely to rise to fresh life, especially as the controversy between the Pharisees and Sadducees, the party of the scribes and the aristocracy, was a struggle for mastery between a secularized hierarchy whose whole interests were those of their own selfish politics, and a party to which God and the exact fulfilment of the law according to the scribes were all in all. This doctrine had grown up under Persian and Grecian rule, and no government that possessed or aimed at political independence could possibly show constant deference to the punctilios of the schoolmen. The Pharisees themselves could not but see that their principles were politically impotent; the most scrupulous observance of the Sabbath, for example — and David was the culminating point of legality — could not thrust back the heathen. Thus the party of the scribes, when they came into conflict with an active political power, which at the same time claimed to represent the theocratic interests of Israel, were compelled to lay fresh stress on the doctrine that the true deliverance of Israel must come from God.

But now the Jews were a nation once more, and national ideas came to the front. In the Hasmonaean sovereignty these ideas took a political form, and the result was the secularization of the kingdom of God for the sake of a harsh and rapacious aristocracy. The nation threw itself on the side of the Pharisees; not in the spirit of punctilious legalism, but with the ardour of a national enthusiasm deceived in its dearest hopes, and turning for help from the delusive kingship of the Hasmonaens to the true kingship of Yahweh, and to His vicegerent the king of David’s house. It is in this connexion that the doctrine and name of Messiah appear in the Psalter of Solomon. The eternal kingship of the House of David, so long forgotten, is seized on as the proof that the Hasmonaens have no divine right.

Thou, Lord, art our king for ever and ever. . . . Thou didst choose David as king over Israel, and swearest unto him concerning his seed for ever that his kingdom should never fail before Thee. And for our sins sinners (the Hasmonaens) have risen up over us, taking with force the kingdom, which was not promised unto them, but unto David and his seed. But Thou, O Lord, will cast them down and root out their seed from the land, when a man not of our race (Pompey) rises up against them. . . . Because David sinned and I was angry with him for Jezebel, and David at the time that Thou hast appointed, to reign over Israel Thy servant; and gird him with strength to crush unjust rulers; to cleanse Jerusalem from the heathen that tread it under foot, to cast out sinners from Thy inheritance; to break the pride of sinners and all their strength as potter’s vessels with a rod of iron (Ps. ii. 9); to destroy the lawless nations with the word of his mouth (Isa. xi. 4); to gather a body of Israel, and lead them in the ways of God; . . . . He shall divide them by tribes in the land, and no stranger and foreigner shall dwell with them; he shall judge the nations in wisdom and righteousness. Thus the nation shall serve under his yoke; he shall glorify the Lord before all the nations of the earth, that Jerusalem may be in high repute in the beginning. From the ends of the earth all nations shall come to see his glory and bring the weary sons of Zion as gifts (Isa. lx. 1 seq.); to see the glory of the Lord with which God hath crowned him, for he is over them a righteous king taught of God. In his days there shall be no unrighteousness in their midst: for they are all holy and their king the anointed of the Lord (apostes vespers τιμητικῆς καταφύγειν τῆς Χριστοῦ αὐθεντικῆς τῆς Σεβαστῆς). . . .

This conception is traced in lines too far to be those of a first essay; it had doubtless grown up as an integral part of the religious protest against the Hasmonaens. And while the polemical motive is obvious, and the argument from prophecy against the legitimacy of a non-Davidic dynasty is quite in the manner of the scribes, the spirit of theocratic fervour which inspires the picture of the Messiah is broader and deeper than their narrow legalism. In a word, the Jewish doctrine of the Messiah marks the fusion of Pharisaism with the national religious feeling of the Hasmonaean revival. The Pharisees claimed a leader against the Romans as well as deliverance from the Sadducee aristocracy, again sets the idea of the kingship rather than that of resurrection and individual retribution in the central place. Henceforward the doctrine of the Messiah is the centre of popular hope and the object of theological culture. The New Testament is the best evidence of its influence on the masses (see especially Matt. xxi. 9); and the exegesis of the Targums, which in its beginnings doubtless reaches back before the time of Christ, shows how it was fostered by the Rabbinus and preached in the synagogues. Its diffusion far beyond Palestine, and in circles not accessible to such ideas, is proved by the fact that Philo himself (De praem. et poen. § 16) gives a Messianic interpretation of Num. xxiv. 27 (LXX). It must not indeed be supposed that the doctrine was as yet the indisputable part of Hebrew faith which it became when the fall of the state and the antithesis to Christianity threw all Jewish thought into the lines of the Pharisees. It has, for example, no place in the Assumption of Moses or the Book of Jubilees. But, as the fatal struggle with Rome became more and more imminent, the eschatological hopes which increasingly absorbed the mind of the Messiah as a person of the Messiah. In the later parts of the Book of Enoch (the “symbols” of chap. xlv. seq.) the judgment day of the Messiah (identified with Daniel’s “Son of Man”) stands in the forefront of the eschatological picture. Josephus (B. J. vi. 5, § 4) testifies that the belief in the immediate appearance of the Messianic king gave the chief impulse to the war that ended in the destruction of the Jewish state; after the fall of the temple the last apocalypses (Baruch, 4 Ezra) still loudly proclaim the near victory of the God-sent king; and Bar Cochba, the leader of the revolt against Hadrian, was actually greeted as the Messiah by Rabbi Agiba (cf. Luke xxi. 8). These hopes were again quenched in blood; the political idea of the Messiah, the restorer of the Jewish state, still finds utterance in the daily prayer of every Jew (the Shemôneh Eser), and is enshrined in the system of Rabbinical theology; but its historical signification was buried in the ruins of Jerusalem.

1 The Targumic passages that speak of the Messiah are registered by Buxtorf, Lex. Chald., s.v.
2 Messiahs have continued from time to time to appear among the Jews. Such was Serenus of Syria (c. 720 A.D.). Soon after, Messianic hopes were active at the time of the fall of the Omayyads, and led to the apotheosis of Abd Al-Aziz (Abu ‘l-‘Aqsah). But David Alrui (Alroy) appeared among the warlike Jews in Azerbaijan in the middle of the 12th century. The Messianic claims of Abraham Abul-Farag in Saragossa (1209) had a considerable success; and some time at a moment of persecution, and throughout the 16th century the Jews were much stirred and more than one false Messiah appeared. See also SABBATAI, SEBI.
MESSINA

But this proof that the true God of mankind could not be realized in an earthly state, under the limitations of national particularism, was the final refutation of the Old Testament, a hope, a hope, the last conceptions of political Judaism -a new spiritual conception-of the kingdom of God, of salvation, and of the Saviour of God's anointing, had shaped itself through the preaching, the death, and the resurrection of Jesus of Nazareth. As applied to Jesus the name of Messiah lost all its political and national significance. Between the Messiah of the Jews and the Son of Man who came to give His life a ransom for many there was on the surface little resemblance; and from their standpoint the Pharisees reasoned that the marks of the Messiah were conspicuously absent from this Christ. But when we look behind the deeper side of the Messianic conception in the Psalter of Solomon, at the heartfelt longing for a leader in the way of righteousness and acceptance with God which underlies the aspirations after political deliverance, we see that it was in no mere spirit of accommodation to prevailing language that Jesus did not disclaim the name in which all the hopes of the Old Testament were gathered up.

Messianic Parallels.—Within the limits of this article it is impossible to attempt any extended survey of parallels to Hebrew Messianic conceptions drawn from other religions. One interesting attempt to be cited is that of Wellhausen, in his Der Messias des Alten Testaments, 2nd ed., pp. 125-127; Von der Gathäusse, in Kleines lateinisches Wörterbuch, vol. i. pp. 209-211; and Basset, in Etudes sur les origines de la religion chrétienne, p. 529.

"Many are the births that have passed of me and of thee."

"Somewhat similar are the avatars of Vishnu, who becomes incarnate in a portion of his essence on ten occasions to deliver mankind from certain great dangers. Krishna himself is usually regarded as one of these avatars."

"This we may consider as one of the striking parallels which meet us in other religions to that hope of the advent of an ideal king which was one of the features of that larger hope of the salvation of Israel from all evils, the realisation of which can be described in the Psalms of Solomon."

"And a rising up of unrighteousness, then I create myself, for the preservation of the good and for the destroying of evil-doers, and for the establishing of righteousness I arise from age to age."

The interest of parallels between the Babylonian Marduk (Merodach) god of light and Christ as a world saviour are ingeniously set forth by Zimmer in K.A.T., 3rd ed., pp. 376-391, but the total impression which they leave is vague.

It would carry us too far to consider in this place the details of the Jewish conception of the Messiah and the Messianic times as they appear in the later apocalypses or in Talmudic theology. See for the former the excellent summary of Schürer, Geschichte des jüdischen Volkes im Zeitalter Jesu Christi, 3rd ed., vol. ii. pp. 497-556. See also Weber, Jüdische Theologie, ch. xxii. For the whole subject see also Drummund, The Jewish Messiah, and Kuenen, Religio of the Jews, 3rd ed. For the Messianic hopes of the Pharisees, see especially Wellhausen, Pharätzer u. Südtäucher (Greifswald, 1874). In its ultimate form the Messianic hope of the Jews is that which was embodied in the hope of the whole of the world, which was the end of the last troubles of Israel (called by the Rabbins the "birth pang of the Messiah"), which appeared the anointed king, the annihilation of the hostile enemy, the return of the dispersed of Israel, the glory and world-sovereignty of the elect, the new world, the resurrection of the dead and the last judgment. But even the final form of Jewish theology shows much vacillation as to these details, especially as regards their sequence in the mutual relation, thus betraying the inadequacy of the harmonious method by which they were derived from the Old Testament and the stormy excitement in which the Messianic idea was developed. Théodore of Tarsus, for example, an open question, and the Rabbins whether the days of the Messiah belong to the old or to the new world (732 760 or 735 769), whether the resurrection embraces all men or only the righteous, whether it coincides with the Messianic age. Compare MILLennium.

We must also pass over the very important questions that arise as to the gradual extirpation of the New Testament idea of the Christ from the elements of Jewish political doctrine which had so strongly held a many of the first disciples—the relation, for example, of the New Testament Apocalypse to contemporary Jewish thought. A word, however, is necessary as to the Rabbinical doctrine of the Messiah. We know that the name of Messiah was the son of Joseph or son of Ephraim, who in Jewish theology is distinguished from and subordinate to the victorious son of David. The several forms of the title from the view of the point of contact with Christianity, in which the Rabbins were hard pressed by arguments from passages (especially Isaac, iiii.) which their own exegesis admitted to be Messianic, though it did not accept the Christian inference as to the atoning death of the Messianic king. That the Jews in the time of Christ believed in a suffering and atoning Messiah is, to say the least, unproved and highly improbable. See, besides the books above cited, De Wetten, De Messias en den Nieuwe Testament, and Wünsche, Der Messias; and also Dr. B. H. Hackett, Christ and the Gospel, should be consulted.

MESSINA, a city of Sicily, 7 m. S.S.W. of the promontory of Faro (anc. Promontorium Pelorum), which forms the northern angle of the island, the capital of the province of Messina and the seat of an archbishop. Pop. (1856), 97,074; (1881), 120,497; (1901), 149,778; (1905), 156,812. The site of the town is round the harbour, between two open bays, the straits of Antennaria at the highest point of which is 3707 ft. The straits, which take their name from the town, are here about 3 m. wide, and only a little over 2 m. at the promontory of Faro. The numerous earthquakes from which the city had suffered, notably that in 1783, had left it few remains of antiquity. But it was a flourishing and beautiful city when in 1908 one of the most disastrous earthquakes ever recorded destroyed it totally. The earthquake occurred early in the morning of December 28, and so far as Messina was concerned the damage was done chiefly by the shock and by the fires which broke out afterwards; the seismic wave which reached Messina and the straits of Antennaria, but not far from the town, did a very little damage elsewhere along the strait, notably at Reggio, Calabria, which was also totally destroyed. Many other smaller towns suffered both in Sicily and in Calabria; the loss of life was appalling and the distress widespread, in spite of the prompt assistance rendered by Italian naval and military forces and by the crews of British, Russian and German warships and other vessels, and the contribution of funds for relief works from every part of the world. The immediate seismic focus appeared to be in the straits, but Dr E. Sessa pointed out that it was surrounded by a curved line of earth-fracture, following an arc drawn from a point in the Lipari Islands, from Catanzaro to Etna, and so counterclockwise; within this arc he held that the crust of the earth is gradually sinking, and is in an unstable condition. According to an official estimate the earthquake caused the loss of 17,283 lives.1 (See also EARTHQUAKE.)

The façades of buildings at Messina in great part withstood the earthquake, but even when they did so the remainder of the buildings was destroyed. The cathedral, which was completely wrecked, was begun in 1088 and finished by Roger II. It had a fine Gothic façade; the interior had mosaics in the apses dating from 1330, and the nave contained 26 granite columns. To the right of the high altar stood a picture of the Linus, near Faro, and had a fine wooden roof of 1260. The rest of the edifice was in the baroque style; the high altar (containing the supposed letter of the Virgin Mary to the people of Messina), richly decorated with marbles, lapis lazuli, &c., was begun in 1628 and completed in 1726. The importance of Messina was almost entirely due to its

MESSUAGE—METABOLIC DISEASES

harbour, a circular basin open on the north only, formed by a strip of land curving round like a sickle, from which it took its original name, Zancle (Σάγγλον, or rather δύαγλον, the Sicilian equivalent of the Greek δύκτανον,\(^1\) according to Thucydides, vi. 4).

Zancle was first founded, no doubt on the site of an earlier settlement, by pirates from Cumae, and again more regularly settled, after an unknown interval, by settlers from Cumae under Pericrates, and from Chalcis under Crataemenes, in the first quarter of the 8th century B.C. Mylae must have been occupied as an outpost very soon afterwards, but the first regular colony of Zancle was Himera, founded in 648 B.C. After the capture of Miklys by the Persians in 494 B.C., Skythes, king of Zancle, invited the Ionians to come and settle at Καλύπτης, then in the occupation of the Sicels (the modern Marina di Catania, 25 m. east of Cefalu); but at the invitation of Anaxilas of Regium the Samians proceeded instead to the latter place. About 488 B.C. Anaxilas and the Samians occupied Zancle in the absence of Skythes, and it was then that the name was changed to Messana, as the existence of coins of the Samian type, bearing the new name, proves. About 480, however, Anaxilas thoroughly established his authority at Messana, and the types of coinage introduced by him persisted down to 372 B.C., when he himself zealously supported his son-in-law Terillus in inviting the Carthaginians' invasion of 480 B.C. In 426 the Athenians gained the alliance of Zancle, but soon lost it again, and failed to obtain it in 415.

Messana fell into the hands of the Carthaginians during their wars with Dionysius the elder of Syracuse (397 B.C.). The Carthaginians destroyed the city, but Dionysius recaptured and rebuilt it. During the next fifty years Messana changed masters several times, till Timoleon finally expelled the Carthaginians in 343 B.C. In the wars between Agathocles of Syracuse and Carthage, the city took sides with the Carthaginians. After Agathocles' death, his mercenaries, the Mamertines, treacherously seized the town about 282 B.C. and held it. They came to war with Hiero II. of Syracuse and appealed for help to Rome, which was granted, and this led to a collision between Rome and Carthage, which ended in the First Punic War. Messana was almost at once taken by Rome. At the close of the war, in 241 B.C., Messana became a free and allied city (civitas foederata), and obtained Roman citizenship before the rest of Sicily, probably from Caesar himself. During the civil wars which followed the death of Caesar, Messana held out with Syratus Pompeius; and in 31 B.C. it was sacked by Octavian's troops. After Octavian's proclamation as emperor he founded a colony here; and Messana continued to flourish as a trading port. In the division of the Roman empire it belonged to the emperors of the East; and in A.D. 547 Belisarius collected his fleet here before crossing into Calabria. The Saracens took the city in A.D. 831; and in 1061 it was the first permanent conquest made in Sicily by the Normans. In 1190 Richard I. of England, with his crusaders, passed six months in Messina. He quarrelled with Tancred, the last of the Hauteville dynasty, and sacked the town. In 1194 the city, with the rest of Sicily, passed to H. of France and thence to the emperor Henry VI., who died there in 1197; and after the fall of the Hohenstaufen was coveted for by Peter I., king of Aragon, and Charles I., count of Anjou. At the time of the Sicilian Vespers (1282), which drove the French out of Sicily, Messina bravely defended itself against Charles of Anjou, and repulsed his attack. Peter I., through his commander Ruggiero di Loria, defeated the French off the Farmo; and from 1282 to 1713 Messina remained a possession of the Spanish royal house. In 1571 the fleet fitted out by the Holy League against the Turk assembled at Messina, and in the same year its commander, Don John of Austria, celebrated a triumph in the city for his victory at Lepanto. Don John's statue stands in the Piazza dell' Annunziata. For one hundred years, thanks to the favours and the concessions of Charles V., Messina enjoyed great prosperity. But the internal quibbles between the Merli, or aristocratic faction, and the Malvezzi, or democratic faction, fomented as they were by the Spaniards, helped to ruin the city (1671-1678). The Messinians suspected the Spanish court of a desire to destroy the ancient senatorial constitution of the city, and sent to France to ask the aid of Louis XIV. in their resistance. Louis dispatched a fleet into Sicilian waters, and the French occupied the city. The Spaniards replied by appealing to Holland, who sent a fleet under Ruyter into the Mediterranean. In 1676 the French admiral, Abraham Duquesne, defeated the combined fleet of Holland; but, notwithstanding this victory, the French suddenly abandoned Messina in 1678, and restored it to the Spaniards, who held it until 1806, when it was once more taken by the French. In 1814 the town once more. The senate was suppressed, and Messina lost its privileges. This was fatal to the importance of the city. In 1743 the plague carried off 40,000 inhabitants. The city was partially destroyed by earthquake in 1783. During the revolution of 1848 against the Bourbons of Naples, Messina was bombarded for three consecutive days. In 1854 the deaths from cholera numbered about 15,000. Garibaldi landed in Sicily in 1860, and Messina was the last city in the island taken from the Bourbons and made a part of united Italy under Victor Emmanuel II.

Messina was the birthplace of Diosoarchus, the historian (c. 322 B.C.); Aristocrates, the Peripatetic; Euhemerus, the rationalist (c. 316 B.C.); Stefano Protonotario, Mazzero di Ricco and Tommaso di Modica, presidents of the court of Frederick II. (A.D. 1250); and Antony du Messina, the painter (1447-1500), of whose works one or two are preserved in the museum. During the 15th century the grammarian, Constantine Lascaris, taught in Messina; and Bessarion was for a time archimandrite there. (T. As.)

MESSUAGE (from Anglo-French message, probably a corruption of mésage, ménage, popular Lat. mansiones, from manere, to dwell), in law, a term equivalent to a dwelling-house, and including buildings, orchard, courtilage or court-yard and garden. At one time "messuage" is supposed to have had a more extensive meaning than that comprised in the word "house," but such distinction, if it ever existed, no longer survives.

MESTIZO (adopted from the Spanish, the Portuguese form being mestico, from Lat. miscre, to mix), a term originally meaning a half-breed, one of whose parents was Spanish, and now used occasionally of any half-breed, but especially to denote persons of mixed Spanish (or Portuguese) and American Indian blood. The offspring of such half-breeds are also called mestizoes. The feminine form is mestiza.

MESUREUR, GUSTAVE EMIL EUGÈNE (1847— ), French politician, was born at Marq'en-Baroeul (Nord) on the 2nd of April, 1847. He worked as a designer in Paris, and became prominent as a member of the municipal council of Paris, rousing much angry discussion by a proposal to rename the Parisian streets which bore saints' names. In 1883 he became president of the council. The same year he entered the Chamber of Deputies, taking his place with the extreme left. He joined the L. Bourgeois ministry of 1893-1896 as minister of commerce, industries, and laïcisation, and later, from 1899 to 1902, was vice-president of the Chamber. From 1898 to 1902, and presided over the Budget Commission of 1899, 1901 and 1902. He was defeated at the polls in 1902, but became director of the Assistance Publique. His wife, Amélie de Wally (b. 1853), is well known as a writer of light verse and of some charming children's books.

META, the Latin word for the goal which formed the turning-point for the chariot races in the Roman circus. The metae consisted of three conical pillars resting on a single podium. None have been preserved, but they are shown on coins, gems and terra-cotta bas-reliefs.

METABOLIC DISEASES. All disease is primarily due to alterations (Gr. μεταβολή, change), quantitative or qualitative, in the chemical changes in the protoplasm of some or all of the tissues of the body. But while in some pathological states these modifications lead to structural changes, in others they do not produce gross lesions, and these latter conditions are commonly classified as Functional Diseases. When such
functional disturbances affect the general nutrition of the body they have been termed Metabolic Diseases (Stoffwechselkrankheiten). It is impossible to draw a hard and fast line between functional and organic disease, since the one passes gradually into the other, as is well seen in gout. Nor is it always easy to decide how far the conditions are due merely to quantitative alterations in the metabolism and how far to actual qualitative changes, for it is highly probable that many of the apparently qualitative alterations are really quantitative disturbances in one part of the protoplasmic mechanism, leading to an apparent qualitative change in the total result of the activity.

Obesity.—It is as fat that the surplus food absorbed is stored in the body; but the power of storing fat varies enormously in different individuals, and in some it may be considered pathological. The reasons of this are very imperfectly understood. One undoubted cause of obesity is taking a supply of food in excess of the energy requirements of the individual. The amount of food may be absolutely large, or large relatively to the muscular energy evolved in mechanical work or in heat-production; but in either case, when fat begins to be deposited, the muscular activity of the body tends to diminish and the loss of heat from the surface is reduced; and thus the energy requirements become less, and a smaller diet is sufficient to yield the surplus food. The storage of fat is a hard and fast line between fats and carbohydrates, and possibly indirectly from proteids (see Nutrition). Individuals probably vary in their mode of dealing with these substances, some having the tendency to convert them to fat, some to burn them off at once. Carl von Noorden, however, who has studied the metabolism in cases of obesity, finds no marked departure from the normal. It may be that in some persons there is a very perfect absorption of food, but so far no scientific evidence for this view is forthcoming. In all cases the fat stored is available as a source of energy, and this circumstance is taken advantage of in the various fat "cures," which consist in giving a diet containing enough to cover the requirements of the body, with a supply of fats and carbohydrates insufficient to meet the energy requirements of the individual. This is illustrated by the dietary of some of the best known of these "cures":—

In a normal individual in moderate muscular activity about 3000 Calories per diem are required (see Dietetics), and therefore under the diets of these "cures," especially when accompanied by a proper amount of muscular exercise, the fats stored in the body are rapidly used up.

Diabetes, as distinguished from transitory glycosuria, is produced by a diminution in the power of the tissues to use sugar, which thus accumulates in the blood and escapes in the urine. One great source of energy being unavailable, the tissues have to use more fats and more proteids to procure the necessary energy, and hence, unless these are supplied in very large quantities, there is a tendency to emaciation.

The power of storing and using sugar in the tissues is strictly limited, and varies considerably in healthy individuals. Normally, when about 200 grms. of glucose are taken at one time, some of it appears in the urine within one hour. In some individuals the taking of even 100 grms. leads to a transient glycosuria, while others can take 30 grms. or more and use it all. But even in the same healthy individual the power of using sugar varies at different times and in different conditions, muscular exercise markedly increasing the combustion. Again, some sugars are more readily used than others, and therefore have a less tendency to appear in the urine when taken in the food. Milk-sugar and laevulose appear in the urine more readily than glucose. This power of using sugar possessed by an individual may depend to a small extent on the capacity of the liver to store as glycogen any excess of carbohydrates absorbed from the food, and some slight cases of transient glycosuria may be accounted for by a diminution of this capacity. But the typical form of diabetes cannot be thus explained. It has been maintained that increased production of sugar is a cause of some cases of the disease, and this view has been supported by Claude Bernard's classical experiment of producing glycosuria by puncturing the floor of the fourth ventricle in the brain of the rabbit. But after such puncture the glycosuria occurs only when glycogen is present in the liver. It is transient and has nothing to do with true diabetes. The fact that various toxic substances, e.g. carbon monoxide, produce glycosuria has been used as an argument in support of this view, but they too are a cause, merely confusing the conversion of glycogen to glucose, and are effective only when the liver is charged with the former substance. At one time it was thought that the occurrence of glycosuria under the administration of phlorizin proved that diabetes is due to a poison. But the fact that, while sugar appears abundantly in the urine under phlorizin, it is not increased in the blood, shows that the drug acts not by diminishing the power of the tissues to use sugar, but by increasing the excretion of sugar through the kidneys and thus causing its loss to the body. Hence the tissues have to fall back upon the proteids, and an increased excretion of nitrogen is produced. This, however, is a totally different condition from diabetes.

Anything which produces a marked diminution in the normally limited power of the tissues to use sugar will cause the disease in a lighter or graver form. As age advances the activity of the various metabolic processes may diminish irregularly in certain individuals, and it is possible that the loss of the power of using sugar may be sooner impaired in some than in others, and thus diabetes be produced. But Minkowski and von Mering have demonstrated, by experiments upon animals, that pathological changes in the pancreas have probably a causal relation to the disease with the disease. They found that excision of that organ in dogs, &c., produced all the symptoms of diabetes—appearances of sugar in the urine, its increased amount in the blood, the rapid breaking-down of proteids, and the resulting emaciation and azoturia. At the same time the absorption from the intestines of proteids, fats and carbohydrates was diminished. How this pancreatic diabetes is produced has not been explained. It has been suggested that the pancreas forms an internal secretion which stimulates the utilization of sugar in the tissues. Though in a certain number of cases of diabetes disease of the pancreas has been found, other cases are recorded where grave disease of that organ has not produced this condition. But the apparent extent of a lesion is often no measure of the depth to which the functions of the structure in which it is situated are altered, and it is very possible that the functions of the pancreas may in many cases be profoundly modified without our methods of research being able to detect the change. The pancreas consists of two parts, the secreting structure and the epithelial islets, and one or other of these may be more specifically involved, and thus alteration in digestion and absorption on the one hand, and changes in the utilization of carbohydrates on the other, may both be produced. Further, large doses of extracts of the supra-renal bodies cause glycosuria and an increase of sugar in the blood, but the relationship of this condition to diabetes has not yet been investigated.

The disease may be divided into two forms:—

1. Slight Cases.—The individual can use small quantities of sugar, but the taking of larger amounts causes glycosuria. Assuming that the energy requirements of an individual are met by a diet of—

</tbody>
</table>

then if only 100 grms. of glucose can be used, the energy value of 300 grms., i.e. 1250 Calories, must be supplied from proteids and fats. To yield this, 300 grms. of proteids or 132 grms. of fats would be required. If these are not forthcoming in the diet, they must
be supplied from the tissues, and the individual will become emaciated; hence a diabetic on an ordinary diet is badly nourished, and hence the huge appetite characteristic of the disease.

2. Grave Cases.—From the products of the splitting of proteins sugar may be formed, and it is in the liver, and in the more serious form of the disease, even when carbohydrates are excluded from the food, a greater or lesser quantity of the sugar thus formed enters the blood, and even under the most extraordinary circumstances of protein diet can yield 113-5 grms. of glucose, i.e. 1 grm. of nitrogen will be set free for each 7·5 grms. of glucose formed. In the urine of grave cases of diabetes on a protein diet, the proportion of nitrogen to sugar is found to be 3·5 : 1. This may mean that the theoretically possible amount of sugar is not yielded, or that some of the sugar formed is used in the economy. Both hypotheses may be correct, but we do not believe the fact that even in grave cases the decomposition of protein may be diminished by giving sugar, and that in muscular exercise the proportion of sugar may fall.

In the course of the disease the amount of sugar which the tissues can use varies from day to day. It is in the utilization of glucose—the normal sugar of the body—that the tissues chiefly fail. Many diabetics are able to use lactulose, or the inulin from which it is derived, and lactose (milk-sugar) to a certain extent. It has, however, been observed that under the administration of these sugars the excretion of glucose may be increased, the tissues, apparently by using the foreign sugar, allowing part of the glucose with the urine to be absorbed.

The increased decomposition of protein, rendered necessary to supply the energy not forthcoming in the sugar, leads to the appearance of a large quantity of nitrogen in the urine—azoturia—and it also throws the balance of the various acids. Sulphuric and phosphoric acid are formed by oxidation of the sulphur and phosphorus in the protein molecule. Organic acids of the lower fatty acid series and aceto-acetic acid with their derivative acetone also appear in the course of the decomposition.

They are actually formed from the disintegration of proteins and in part from fats, as the result of a modified metabolism induced by the withdrawal of carbohydrates. To neutralize them ammonia is developed and hence the proportion of ammonia in the urine is increased. By the development of these various acids the alkalinity of the blood is diminished. The development of these acids in large quantities is associated with extensive decomposition of protein, and is sometimes indicative of the onset of a comatose condition, which seems to be due rather to an acid intoxication than to the special toxic action of the uric acid.

Myxœdema.—The thyroid gland forms a material which has the power of increasing the metabolism of proteins and of fats; and when the thyroid is removed, a condition of sluggish metabolism, with low temperature and a return of the connective tissues to an embryonic condition, supervenes, accompanied by the appearance of depression of the mental functions and by other nervous symptoms. The disease myxœdema, which was first described by Sir William Gull in 1873, was shown by Ord in 1878 to be due to degenerative changes in the thyroid gland. It affects both sexes, but chiefly females, and is characterized by a peculiarly puffy cutaneous condition, involving the skin of the face and hands, the swelling of the tissues, the puffy cutaneous condition, the enlargement of the thyroid gland, and a low temperature, and mental hebephrenia.

The symptoms are similar to those produced by removal of the thyroid, and are indicative of a condition of diminished activity of metabolism. The nervous symptoms may be in part due to some alteration in the metabolism, leading to the formation of toxic substances. The administration of thyroid gland extract causes all the symptoms to disappear.

Cretinism may now be defined as myxœdema in the infant, and it has been definitely proved to be associated with non-development of the thyroid gland. The characteristic symptoms of the disease are all due to diminished metabolism, leading to retarded development, and the treatment which has proved of service, at least in some sporadic cases, is the administration of various thyroid preparations.

Exophthalmic Gout.—Graves's Disease or Basedow's Disease.—This disease chiefly affects young women, and is characterized by three main symptoms: increased rate and force of the heart's action, protrusion of the eyeballs, and enlargement of the thyroid gland. The patient is nervous, often sleepless, and generally becomes emaciated and suffers from slight febrile attacks. The inflammatory condition of the tissues and disturbance of the metabolism on the heart is the most prominent symptom, and the enlargement of the thyroid gland may not be manifest.

Various theories as to the pathology of the condition have been advanced, but in the light of our knowledge of the physiology of the thyroid the most probable explanation is an increased functional activity of that gland or of changes in the parathyroids.

Gout has often been divided into the typical and atypical forms. The first is undoubtedly a clinical and pathological entity, but the second, though containing cases of less severe forms of true gout, is largely constituted of imperfectly diagnosed morbid conditions. The accumulation of urate of soda, in the tissues in gout formerly led physicians to believe in a causal relationship between an increased formation of that substance and the onset of the disease. Sir A. Garrod's investigations, however, seemed to indicate that diminished excretion rather than increased production is the cause of the condition. He found an accumulation of uric acid in the blood and a diminution in its amount in the urine during the attack. That uric acid is increased, the blood is undoubtedly, but the changes described by Garrod in the urine, and considered by him as indicative of diminished excretion and retention, are rendered of less value by the imperfections of the analytic method employed. More recent work with better methods has thrown still further doubt upon the existence of such a relationship, and points rather to the accumulation of uric acid being, like the other symptoms of the condition, a result of some unknown modification in the metabolism, and a purely secondary phenomenon. The important fact that in leucæmia (von Jaksch), in lead-poisoning (Garrod), and in other pathological conditions, uric acid may be increased in the blood and in the urine, without any gouty symptoms supervening, is one of the strongest arguments against the view that the gouty inflammation is not caused by the deposit of urate of soda, seems to be indicated by the occurrence of cases in which there is no such deposition. The source of the uric acid which is so widely deposited in the gouty is largely the phosphorus containing nucleins of the food and tissues. These in their decomposition yield a series of di-ureides, the purin bodies, of which uric acid is one. Their excretion is increased when substances rich in nuclei, e.g. sweetbreads, &c., are administered. While uric acid itself has not been demonstrated to have any injurious effect, it has been found to produce toxic symptoms. After the discovery of this source of uric acid, physiologists for a time inclined to regard it as the only mode of production. But it must be remembered that in birds uric acid is formed from the ammonia compounds coming from the intestine and muscles, just as ura is formed from the same substance in mammals. Uric acid is a di-ureide—a body composed of two urate molecules linked by acetic acid—an unsaturated propionic acid. It is therefore highly probable that in many conditions the conversion of the ammonium urate into uric acid is not complete, and that a certain amount of uric acid is formed apart from the decomposition of nucleins.

Sir William Roberts has adduced evidence to show that uric acid circulates in the blood in a freely soluble combination or quadrurate—that is, a compound in which one molecule of an acid salt BH₄⁻ is linked to a molecule of the acid BH₂U₄⁻. These compounds are said to be readily decomposed and the bi-urates formed, which are at first gelatinous but become crystalline. The deposition of urate of soda in joints, &c., has been ascribed to this change. Francis Tunnicliffe, however, has published the results of certain investigations which throw doubt upon this explanation. The most recent investigations on the metabolism of the gouty have shown that there is undoubtedly a slowing in the rate of elimination of uric acid and also of the total nitrogen of the urine with occasional sudden increases sometimes connected with a gouty paroxysm, sometimes independent of it. Whether this is due to the action of some toxin developed in the body or is caused by a constitutional renal inadequacy is difficult to decide. Certain it is these renal diseases often develop in the course of gout.

Rheumatism.—Rheumatic fever was formerly regarded as due to some disturbance in the metabolism, but it is now known to be a specific micro-organismal disease. The whole clinical picture is that of an infective fever, and it is closely related to gonorrhœal rheumatism and to certain types of pyæmia. A number of independent observers have succeeded in isolating from cases of rheumatic fever a diplococcus which produces similar
METABOLISM—METAL

symptoms in the rabbit to those which characterize the disease in man.

Excluding the peculiar changes in the joints which occur in rheumatoid arthritis and in Charcot's disease, and which are almost certainly primary affections of the nervous system, it is found that a large number of individuals suffer from pain in the joints, in the muscles, and in the fibrous tissues, chiefly on exposure to cold and damp or after inclemencies of diet. This so-called chronic rheumatism appears to be a totally distinct condition from rheumatic fever; and although its pathology is not determined, it looks as if it were due either to a diminished elimination or an increased production of some toxic substance or substances, but so far we have no evidence as to their nature.

Nickels is undoubtedly a manifestation of a profound alteration of the metabolism in childhood, but how far it is an idiopathic condition and how far a result of the action of toxins introduced from without is not yet definitely known. Kassowitz long ago showed that the bone changes are similar to those which can be produced in animals by chronic phosphorus poisoning, and that they are really irritative in nature. Spillmann, in his work Le Rachitisme, discusses the evidence regarding the action of various conditions, and comes to the conclusion that there is no evidence that it is due to a mere primary disturbance of the metabolism, or to excessive production of lactic acid, or to any specific micro-organism poisoning. But he adds evidence, perhaps not very convincing, that in the disease there is a specific intoxication derived from the alimentary canal and provoking inflammatory lesions in the bones.

See generally Carl von Noorden, Metabolism and Practical Medicine (1907).

METABOLISM (from Gr. μεταβολή, change), the biological term for the process of chemical change in a living cell (see PHYSIOLOGY).

METAL (from Fr. from Lat. metallum, mine, quarry, and deriv. from Gr. μεταλλόω, in the sand, mixed up, probably connected with μεταλλάω, to search after, explore, search, after, διάλλος, other). Originally applied to gold, silver, copper, iron, tin, lead and bronze, i.e. substances having high specific gravity, malleability, opacity, and especially a peculiar lustre, the term "metal" became generic for all substances with these properties.

In modern chemistry, however, the metals are a division of the elements, the members of which may or may not possess all these characters. The progress of science has, in fact, been accompanied by the discovery of some 70 elements, which may be arranged in order of their \"metallic\" properties as above indicated, and it is found that while the end members of the series, are most distinctly metallic (or non-metallic), certain central members, e.g. arsenic, may be placed in either division, their properties approximating to both metallic and non-metallic. One chemical differentiates utilizes the fact that metals always form at least one basic oxide which yields salts with acids, while non-metals usually form acidic oxides, i.e. oxides which yield acids with water. This definition, however, is highly artificial and objectionable on principle, because when we speak of metals we think not of their chemical relations, but of a certain sum of mechanical and physical properties which unites them all into one natural family.

All metals, when exposed in an inert atmosphere to a sufficient temperature, assume the form of liquids, which all present the following characteristic properties. They are (at least practically) non-transparent; they reflect light in a peculiar manner, producing what is called \"metallic lustre.\" When kept in non-metallic vessels they take the shape of a convex meniscus. These liquids, when exposed to higher temperatures, some sooner than others, pass into vapours. What these vapours are like is not known in many cases, since, as a rule, they can be produced only at very high temperatures, precluding the use of transparent vessels. Silver vapour is blue, potassium vapour is green, many others (mercury vapour, for instance) are colourless. The liquid metals, when cooled down sufficiently, some at lower, others at higher, temperatures freeze into compact solids, endowed with the (relative) non-transparency and the lustre of their liquids. These

frozen metals in general form compact masses consisting of aggregates of crystals belonging to the regular or rhombic or (more rarely) the quadratic system. Compared with non-metallic solids, they in general are good conductors of heat and of electricity. But their most characteristic, though not perhaps their most general, property is that they combine in themselves the apparently incompatible properties of elasticity and rigidity on the one hand and plasticity on the other. To this remarkable combination of properties more than to anything else the ordinary metals owe their wide application in the mechanical arts. In former times a high specific gravity used to be quoted as one of the characters of the genus; but this no longer holds, since we now know a series of metals lighter than water.

Colour. — Gold is yellow; copper is red; silver, tin, and some others are pure white; the majority are greyish.

Reflection of Light. — Polished metallic surfaces, like those of other solids, divide any incident ray into two parts, of which one is refracted while the other is reflected—with this difference, however, that the former is completely absorbed, and that the latter, in regard to polarization, is quite differently affected. The following values are due to Rubens and Hagen (Ann. der Phys., 1900, p. 357); they express the percentage of incident light reflected. The superiority of silver is obvious.

Crystalline Form and Structure. — Most (perhaps all) metals are capable of crystallization. The crystals belong to the following systems: regular system—silver, gold, palladium, mercury, copper, iron, lead; quadratic system—tin, potassium; rhombic system—antimony, bismuth, tellurium, zinc, magnesium. Perhaps all metals are crystalline, only the degree of visibility of the crystalline arrangement is very different in different metals, and even in the same metal varies according to the slowness of solidification and other circumstances.

Antimony, bismuth and zinc exhibit a very distinct crystalline structure: a bar-shaped ingot readily breaks, and the crystal faces are distinctly visible on the fracture. Tin also is crystalline: a thin bar, when bent, "creaks" audibly from the sliding of the crystal faces one over another; but the bar is not easily broken, and exhibits an apparently non-crystalline fracture. — Class I.

Gold, silver, copper, lead, aluminium, cadmium, iron, pure, nickel and cobalt are practically amorphous, the crystals (where these being so closely packed as to produce a virtually homogeneous mass. — Class II.

The great contrast in apparent structure between cooled ingots of Class I. and of Class II. appears to be owing chiefly to the fact that the transformations in the latter typeize in the regular system, metals of Class I. form rhombic or quadratic crystals. Regular crystals expand equally in all directions; rhombic and quadratic expand unequally, and in directions that are in a different position in different crystals. The crystals immediately after their formation to be in absolute contact with one another all round, then, in the case of Class I., such contact will be maintained on cooling, while in the case of Class I. the contraction is such that the crystals lie in general have different values in any two neighbouring crystals, and the crystals consequently become slightly detached from one another. The crystalline structure which exists on both sides becomes visible only in the metals of the first class, and only then manifests itself as brittleness.
Closely related to the structure of metals is their degree of "plasticity" (susceptibility of being constrained into new forms without breach of continuity). This term of course includes as special cases the qualities of "malleability" (capability of being flattened out under the hammer) and "ductility" (capability of being drawn into wire). But these two latter qualities do not always go parallel to each other, for this reason amongst others—that ductility in a higher degree than malleability is determined by the tenacity of a metal. Hence tin and lead, though very malleable, are little ductile. The quality of plasticity is developed to very different degrees in different metals, and even in the same species it depends upon temperature, and may be modified by mechanical or physical operations.

A bar of zinc, for instance, as obtained by casting, is very brittle; but when heated to 205° C., it becomes sufficiently plastic to be rolled into the thinnest sheet or to be drawn into wire. Such sheet or wire then remains flexible after cooling, the originally only loosely cohering crystals having got intertwined and forced into absolute contact with one another—an explanation supported by the fact that rolled zinc has a somewhat higher specific gravity (7:2) than the original ingot (6:9). The same metal, when heated to 205° C., can be powdered in a mortar. Pure iron, copper, silver, and other metals are easily drawn into wire, or rolled into sheet, or flattened under the hammer. But all these operations render the metals harder, and detract from their plasticity. Their original softness can be restored to a certain extent by "annealing," i.e. by heating them to redness and then quenching them in cold water. In the case of iron, however, this applies only if the metal is perfectly pure. If it contains a few parts of carbon, the annealing process, instead of softening the metal, gives it a "temper," meaning a higher degree of hardness and plasticity (see below).

What we have called plasticity must not be confused with the notion of "softness," which means the degree of facility with which the plasticity of a metal can be discounted. Thus lead is far softer than silver, and yet the latter is by far the more plastic of the two, so brittle that it can be powdered in a mortar. The experiments of H. E. Tresca show that the plasticity of certain metals at least goes considerably farther than had been supposed.

He operated with lead, copper, silver, iron and some other metals. Round disks made of these substances were placed in a closely fitting cylindrical cavity drilled in a block of steel, the cavity having a circular aperture of two or four centimetres below. By an hydraulic press a pressure of 100,000 kilos was made to act upon the disks, when the metal was so "flowed" out of the hole like a viscous liquid. In spite of the immense resistance of parts to this "flow" no breach of continuity. What came out below was a compact cylinder with a rounded bottom, consisting of so many layers superimposed upon one another. Parallel experiments with layers of dough or putty showed that some cohering material proved that to the parther, in all cases moved along the same tracks as would be followed by a flowing cylinder of liquid. Of the better known metals potassium and sodium are the softest; they can be kneaded between the fingers, and can be rolled into sheets thousand and the latter being the softest of the metals used in the arts. Among these the softness decreases in the following order: lead, pure silver, pure gold, tin, copper, aluminium, platinum, pure iron. As liquidity might be looked upon as the ne plus ultra of softness, this is the right place for stating that, while most metals, when heated up to their melting points, pass pretty abruptly from the solid to the liquid state, platinum and iron first assume, and throughout a long range of temperatures retain, a condition of viscous semi-solidity which enables two pieces of them to be "welded" together by pressure into one continuous mass.

According to Prechtl, the ordinary metals, in regard to the degree of facility or perfection with which they can be hammered flat on the anvil, rolled out into sheet, or drawn into wire, form the following descending series:

Hammering. Rolling into Sheet. Drawing into Wire.

</tr>
</tbody>
</table>

To give an idea of what can be done in this way, it may be stated that gold can be beaten out of leaf of the thickness of \(10^{-4}\) mm.; and that platinum, by judicious work, can be drawn into wire \(10^{-6}\) mm. thick.

By the "hardness" of a metal we mean the resistance which it offers to the file or engraver's tool. Taking it in this sense, it does not necessarily measure, e.g. the resistance of a metal to abrasion by friction. Thus, for instance, 10% aluminium bronze is scratched by an ordinary steel knife-blade, yet the sets of needles used for perforating postage stamps last longer if made of aluminium bronze than if made of steel.

**Elasticity.**—All metals are elastic to this extent that a change of form, brought about by stresses not exceeding certain limit values, will disappear on the stress being removed. Strains exceeding the "limit of elasticity" result in permanent deformation or (if sufficiently) in rupture. Referring the reader to the article ELASTICITY for the theoretical and to the STRENGTH OF MATERIALS for the practical aspects of this subject, we give here a table of the "modulus of elasticity," E (column 2), for millimetre and kilogramme. Hence total, as the elongation in millimetres per metre length per kilo. Column 3 shows the charge causing a permanent elongation of 0.05 mm. per metre, which, for practical purposes, Wertheim takes as giving the limit of elasticity; column 4 gives the breaking strain. These values may vary within certain limits for different specimens.

**Specific Gravity.**—This varies in metals from \(394\) (lithium) to \(22.5\) (uranium), and is extremely low in the case of aluminium (2.7). It is a function of temperature and of previous physical and mechanical treatment. It has in general one value for the powdery metal as obtained by reduction of the oxide in hydrogen below the melting point of the metal, another for the metal in the state which it assumes spontaneously on freezing, and this latter value, in general, is modified by hammering, rolling, drawing, &c. These mechanical operations do not necessarily add to the density; stamping, it is true, does so necessarily, but rolling or drawing occasionally causes a diminution of the density. Thus, for instance, chemically pure iron in the ingot has the specific gravity 7.84; when it is rolled out into thin sheet, the value falls to 7.62; when drawn into thin wire, to 7.58. The following table gives the specific gravities of many metals. Where special statements are not made, the numbers hold for the ordinary temperature (15° to 17° or 20° C.), referred to water of the same temperature as a standard, and to hold for the natural frozen metal.

**Thermal Properties.**—The specific heats of most metals have been determined. The general result is that, conformably with Dulong and Petit's law, the "atomic" weights of all come to very nearly the same value (about 64); i.e., atomic weight by specific heat is 64. This we have found by theory $64 = 0.959$, and by experiment $65.70$ for $10^2$ to $10^3$ C.

The expansion by heat varies greatly. The following table gives the linear expansions from $0^\circ$ to $100^\circ$ C. according to Fizeau (Comptes rendus, lxxxvii. 1125), the length at $0^\circ$ being taken as unity.

</tbody>
</table>

The coefficient of expansion is constant for such metals only as crystallize in the regular system; the others expand differently in the directions of the different axes. To eliminate this source of uncertainty these metals were employed as compressed powders. The cubical expansion of mercury from $0^\circ$ to $100^\circ$ C. is $0.01803$ (Regnault). (See Thermometry.)

**Fusibility and Volatility.**—The fusibility in different metals is very different, as shown by the following table, which, besides including all the fusing points in degrees C. of metals which have been determined numerically, indicates those of a selection of other metals by the positions assigned to them in the table.

In electric furnace

For practical purposes the volatility of metals may be stated as follows:

1. Distillable below reedness: mercury.
2. Distillable at red heat: cadmium, alkali metals, zinc, magnesium.
3. Volatilized more or less readily when heated beyond their fusing points in open crucibles: antimony (very readily), lead, bismuth, tin, silver.
4. Barely so: gold (copper).
5. Practically non-volatile: iron, nickel, cobalt, aluminium; also lithium, barium; the rest of the alkali.

The oxyhydrogen flame silver boils, forming a blue vapour, while platinum volatilizes slowly, and osmium, though insubstantial, very readily.

**Latent Heats of Liquefaction.**—Of these we know little. The following numbers are due to Person—ice, it may be stated, being 50.

The latent heat of vaporization of mercury was found by Marignac to be 103 to 106.

**Conductivity.**—Conductivity, whether thermic or electric, is very differently developed in different metals; and, as an exact knowledge of these conductivities is of great importance, much attention has been given to their numerical determination (see Conductivity, Electrical, and Conduction of Heat). The following table gives the electric conductivities of a number of metals as determined by Matthiessen, and the relative internal thermal conductivities of (nominally) the same metals as determined by Wiedemann and Franz, with rods about 5 mm. thick, of which one end was kept at 100°C, the rest of the rod in a "vacuum" (of 5 mm. tension) at 19°C. Matthiessen's results, except in the two cases noted, are from his memoir in Pogg. Ann., 1858, cii. 428.

### Magnetic Properties
- Iron, nickel and cobalt are the only metals which are attracted by the magnet and can become magnets themselves. But in regard to their power of retaining their magnetism some of them comes at all up to the compound metal steel. See MAGNETISM.

### Chemical Changes
- Metals may unite chemically both with metals and with non-metals. The compounds formed in the first case, which may be either definite chemical compounds or solid solutions, are discussed under ALLOYS; in this place only combinations with non-metals are discussed, it being premised that the free metal takes part in the reaction.

### Metallic Substances Produced by the Union of Metals with Small Proportions of Non-Metallic Elements
- **Hydrogen**, as was shown by Graham, is capable of uniting with or being occluded by certain metals, notably with palladium (p.), into metal-like compounds.
- Oxygen—Mercury and copper and some other metals are capable of dissolving their own oxides. Mercury, by doing so, becomes viscid and unfit for its ordinary applications. Copper, when pure, is not easily attacked by it, but is liable to form a layer of oxide on its surface.
- Phosphorus—The remark just made might be said to hold for phosphorus were it not for the existence of what is called “phosphorus-bronze,” an alloy of copper with phosphorus (5 % of phosphorus) having valuable properties. According to Abell, the most favourable effect is produced by from 1 to 1 1/2 % of phosphorus. Such an alloy can be cast like ordinary bronze, but exerts a greater hardness, elasticity, toughness and tensile strength.
- Carbon—Most metals when molten are capable of dissolving at least small proportions of carbon, which, in general, leads to a deterioration in mechanical, except in the case of iron, which by the addition of small percentages of carbon gains in elasticity and tensile strength with little loss of plasticity (see IRON).
- Silicon, so far as we know, behaves to metals pretty much like carbon, but our knowledge of facts is limited. What is known is that iron is an essential alloy of iron proper with 2 to 6 % of carbon and more or less of silicon (see IRON). Alloys of copper and silicon were prepared by Deville in 1863. The alloy in 12 % of silicon is white, hard and brittle. When distilled down to 4-8 % it assumes the colour and fusibility of bronze, but, unlike it, is tenacious and ductile like iron.

### Action of the More Ordinary Chemical Agents on Simple Metals
- The metals to be referred to are always understood to be given in the compact (frozen) condition, and that, wherever metals are enumerated as being similarly attacked, the condition of air is the same, except that the order in which the several metals are named—the more readily changed metal always standing first.
- Water, at ordinary or slightly elevated temperatures, is decomposed by all or less readily, with evolution of hydrogen gas and formation of a basic hydrate, by (1) potassium (formation of KHO), sodium (NaH), lithium (LiOH), barium, strontium, calcium (BaH₂O₄, &c.); (2) magnesium, zinc, manganese (MgO₂H₂, &c.).

1 Published in 1860, and declared by Matthiasen to be more exact than the old numbers.
METALLOGRAPHY

a certain range of temperatures situated close to its boiling point, combines slowly with oxygen into the red oxide, which, however, breaks down at a higher temperature. Of all others, which, when heated in oxygen or air, are converted, more or less readily, into stable oxides. Potassium, for example, yields peroxide, K₂O₂ or K₃O₄; sodium gives NaO₃; the barium-group metals, as well as magnesium, zinc, lead, and calcium, are converted at once into monoxide MoO. Bismuth and antimony give the latter (the very readily) sesqui-oxide (Bi₂O₃ and Sb₂O₅), the latter being capable of passing into SO₃. In the case of aluminium, which is kept in a solid mass with all metallic matter, is only oxidized at a white heat, and then very slowly, into alumina, Al₂O₃. Tin, at high temperatures, passes slowly into oxide, SnO₂.

Amongst the better known metals, gold and aluminium are the only ones which, when heated with sulphur or in sulphur vapour remain unchanged. All the rest, under these circumstances, are converted into sulphides. The metals of the alkalis and alkaline earths, and the tin, bismuth, and antimony, are readily converted into sulphides, particularly at high temperatures. Of the heavy metals, copper is the one which exhibits by far the greatest avidity for sulphur, its sulphide CuS being the stabelst of all heavy metallic sulphides in opposition to dry reactions.

Chlorine.—All metals, when treated with chlorine gas at the proper temperatures, pass into chlorides. In some cases the chlorine is taken up in two instalments, a lower chlorine being produced first, in water, and ultimately into a higher chloride. Iron, for instance, is converted first into FeCl₂, ultimately into FeCl₃, which practically means a mixture of the two chlorides, or pure FeCl₃ as a final product. Of the several products, the chlorides of gold and platinum (AuCl₃ and PtCl₃) are readily one of the metals heated together, the temperature of sublimation associate into metal and chlorine. The ultimate chlorination product of copper, CuCl₂, when heated to redness, decomposes into the lower chloride, CuCl, and chlorine. All the rest, when heated by themselves, volatilize some at lower, others at higher temperatures.

Of the several individual chlorides, the following are liquids or solids which have volatile enough to be distilled from glass vessels: AsCl₃, SbCl₃, SnCl₄, BiCl₃, HgCl₂, the chlorides of arsenic, antimony, tin, bismuth, mercury respectively. The following are readily volatilized in a current of chlorine, at a red heat: AlCl₃, GaCl₃, FeCl₃, the chlorides of aluminum, chromium, iron. The following, though volatile at higher temperatures, are not volatilized at dull redness: KCl, NaCl, LiCl, LiCl₂, NiCl₂, CoCl₃, MnCl₂, ZnCl₂, MgCl₂, PbCl₂, AgCl, the chlorides of sodium, potassium, iron, nickel, cobalt, manganese, zinc, magnesium, lead, silver. Somewhat less volatile than the last-named group are the chlorides (MCl₃) of barium, strontium and calcium.

Metallic chlorides, as a class, are readily soluble in water. The following are the most important exceptions: silver chloride, AgCl, and mercuric chloride, HgCl₂, are absolutely insoluble; lead chloride, PbCl₂, and tin chloride, SnCl₂, are very sparingly soluble in water. The chlorides AsCl₃, SbCl₅, BiCl₃ are at once decomposed by (liquid) water, with formation of oxide (As₂O₃) or oxychlorides (SbOCl₂, BiOCl) and hydrochloric acid. The chlorides MgCl₂, AlCl₃, CrCl₃, MnCl₂, NiCl₂, CoCl₃, show similar decomposition when exposed to air or water in the heat. The same holds in a limited sense for ZnCl₂, CdCl₂, InCl₃, and even CaCl₂. All chlorides, except those of silver and mercury (and, of course, those of gold and platinum), are oxidized by steam at high temperatures, with elimination of hydrochloric acid.

For the characters of metals as chemical elements please see the special articles on the individual metals.

Preparation of the Specimen.—Experience alone can enable the operator to determine what proportions of metal or alloy will afford a trustworthy sample of the whole. In studying a series of binary alloys it has been found advantageous in certain cases to obtain one section which will show in a general way the variation in structure from one end of the series to the other. This has been effected by pouring the lighter constituent carefully on the surface of the heavier constituent, and allowing solidification to take place. A section through the culot so obtained will show a gradation in structure from pure metal on one side to pure metal on the other. A thin slice of metal is usually cut by means of a hack-saw driven by mechanism. The thickness of the piece should not be less than ½ in. In order that it may be firmly held between the fingers it should not be less than 1 in. The preliminaries of polishing are effected by emery paper placed preferably on wooden disks capable of being revolved at a high rate of speed. The finest grade of emery paper that can be obtained is used towards the end of the operation. Before use the finer papers should be rubbed with a hard steel surface to remove any coarse particles. The completion of the operation of polishing is generally effected on wet cloth or parchment covered with a small amount of carefully washed jeweller’s rouge. Various mechanical appliances are employed to minimize the labour and time required for the polishing. These usually consist of a series of interchangeable revolving disks, each of which is covered with emery paper, cloth or parchment, according to the particular stage of polishing for which it is required. In the case of brittle alloys and of alloys having a very soft constituent, which during polishing tends to spread over and obliterate the harder constituents, polishing is in many cases altogether avoided by casting the alloy on the surface of glass or mica. In this way, with a little care, a perfect surface is obtained, and it is only to do the polishing under a magnifying glass. In adopting this method, however, instances have occurred in which the removal of the cast surface has shown a structure differing considerably from the original.

Polishing in Bas-Relief.—If the polishing be completed with fine rouge on a sheet of wet parchment, placed upon a comparatively soft base such as a piece of deal, certain soft constituents of an alloy may often be eroded in such a manner as to leave the heaviest portions in relief. For the later stages of polishing H. L. Le Chatelier recommends the use of alumina obtained by the collection of ammonium alum, and for the final polish of soft metals, chromium oxide. Although in some cases a pattern becomes visible after polishing, yet more frequently a mirror-like surface is produced in which no pattern can be detected, or if there is a pattern it is blurred, as if seen through a veil or mist. This is due to a thin layer of metal which has been dragged, or smeared, uniformly over the whole surface by the friction of the polishing process. Such a surface layer is formed in all cases of polishing, and the peculiar lustre of burnished silver or steel is probably due to this layer. But to the metallographist it is an inconvenience, as it interferes with his work. Le Chatelier matches this up to the pattern. It is therefore desirable to conduct the polishing so as to make this layer as thin as possible: it is claimed for alumina that it can be so used as to produce a much thinner surface layer than that due to the employment of rouge. The surface layer is very readily removed by appropriate liquid reagents, and, the true surface of the metal having been laid bare, the etching reagent acts differently on the individual substances in the alloy and the pattern can thus be emphasized to any required extent. Osmond divides etching reagents into three classes—acids, alkalies and complex solutions. The acids are mostly about 10% of hydrochloric acid is useful. It is made by mixing 10 grams of potassium bichromate with 10 grams of sulphuric acid in 100 grams of water. The use of nitric acid requires much experience. It is frequently employed in the examination of steels, Sir W. C. Roberts-Austen preferred a 1% solution in alcohol, but many workers use concentrated acid, and effect the etching by allowing a stream of water to dilute the film of acid left on the surface of the specimen after dipping it. Of the halogens, iodine is the most useful. A solution in alcohol is applied, so that a single drop covers half a square inch of surface. The specimen is then washed with alcohol, and dried with a piece of fine linen or chamois leather. Tincture of iodine also affords a means of identifying lead in certain alloys by the formation of a yellow iodide of lead, while the vapour of iodine has in certain cases been
used to tint the constituents. Thin coloured films may often be produced by the oxidation of the specimen when heated in air. This, as a means of developing the structure, in the case of the copper alloys is specially useful. Tinted crystals may thus be distinguished from the investing layer caused by the presence of a minute quantity of another constituent. The temper colours produced by heating iron or steel in air are well known. Carbide of iron is less oxidizable than the iron with which it is intimately associated, and it assumes a brown tint, while the iron has reached the blue stage. These coloured films may be fixed by covering with thin films of gelatine.

In some cases the alloy may be attacked electrolytically by exposing it for a few minutes to a weak electric current in a bath of very dilute sulphuric acid. Certain organic bodies give very satisfactory results. The Japanese, for instance, produce most remarkable effects by simple reagents of which an infusion of certain forms of grass is a not unimportant constituent. In the case of iron and steel a freshly prepared infusion of liquorice root has been found to be most useful for colouring certain constituents of steel. Osmond, who was the first to use this reagent, insisted that it should be freshly prepared and always used under identical conditions as regards age and concentration. His method of applying it was to rub the specimen on parchment moistened with it, but he has subsequently modified this "polish attack" by substituting a 2% solution of ammonium nitrate for the liquorice infusion. In each case a small quantity of freshly precipitated calcium sulphate is used on the parchment to assist the polishing.

Apparatus used in Microscopy.—The method of using the microscope in connexion with a camera for photographic purposes will now be considered. Every micrographer has his own views as to the form of an installation to be adopted, and it will therefore be well to give an illustration of a definite apparatus which has been found to give satisfactory results. It consists of a microscope A with a firm base placed in a horizontal position. The microscope can be connected by a tube B with the expanded camera C, at the end of which is the usual frame to receive the photographic plate. A practised observer can focus on a plate of clear glass by the aid of a subsidiary low-power microscope lens. If a semi-transparent plate is employed it should be as fine as possible. The surface of the table is cut in such a way near H that the observer who is seated may conveniently examine the object on the stage of the microscope, the portion B turning aside for this purpose. The subsequent focusing is effected by a rod, FFF, and gearing attached to the fine adjustment of the microscope, GA; flap J when raised forms the support of the lamp used for illumination. As an illuminant an arc lamp has many advantages, as the exposure of the plate used will seldom exceed a few seconds. The filament of a Nernst lamp can be used as the source of light; though not so brilliant as the arc it possesses the great advantage of perfect immobility. For the best results, especially with high powers, the source of light must be small, so that its image can be focussed on to the surface of the object; this advantage is possessed by both of these illuminants. Next in value comes the acetylene flame, and an incandescent lamp or a gas lamp with a mantle will give good results, but with much longer exposure. Actual illumination is best effected by a Beck vertical illuminator or a Zeiss prism. It is necessary that the lens used for concentrating the light on the illuminator

should be an achromatic one, as colour effects cause trouble in photographing the objects. For lower powers the Lieberkühn parabolic illuminator is useful. Certain groups of alloys show better under oblique illumination, which may be effected by the aid of a good condensing lens, the angle of incidence being limited by the distance of the object from the objective in the case of high magnification. As regards objectives, the most useful are the Zeiss 2 mm., 4 mm. and 24 mm.; two other useful objectives for low powers being 35 mm. and 70 mm., both of which are projecting objectives. A projecting one of power, preferably of low power, should be employed with all but the two latter objectives. The immersion lens, the Zeiss 2 mm., is used with specially thickened cedar oil, and if the distance from the objective to the plate is 7 feet, magnifications of over 2000 diameters can easily be obtained. As regards sensitized plates, excellent results have been obtained with Lumière plates sensitive to yellow and green. The various brands of "process" plates are very serviceable where the contrasts on the specimen are not great. Some reproductions of photo-micrographs of metals and alloys will be found in the plate accompanying the article Alloys.

METALLURGY, the art of extracting metals from their ores; the term being customarily restricted to commercial as opposed to laboratory methods. It is convenient to treat electrical processes of extraction as forming the subjects of Electrochemistry and Electrometallurgy (qq.v.). The following table enumerates in the order of their importance the metals which our subject at present is understood to include; the second column gives the chemical characters of the ores utilized, italics indicating the name of subordinate import. The term "metal" includes carbonate, hydrate, and, when marked *, silicate.

from below. The metallic oxide, partly by the direct action of the carbon with which it is in contact, but principally by that of the charcoal itself, is decomposed. To this cause is due the lower specific gravity of the metal (as iron pyrites (FeS₂), galena (PbS), zinc blende (ZnS), cinnabar (HgS); and (2) complex sulphides, such as the various kinds of sulphuriferous copper ores (all substantially compounds or mixtures of sulphides and sulphates) as iron, a reduced iron; a freed iron) must be liberate the antimony and copper; rothgitsger, sulphide of silver, antimony and arsenic; fahlerz, sulphides of arsenic and antimony, combined with species of copper, iron, mercury, silver; and mixtures of these and other sulphides with one another.

In treating a sulphureous ore, the first step as a rule is to subject it to oxidation by roasting it in a reverberatory or other furnace, which leads to the burning away of all but the arsenic and part of the sulphur. The effect on the several individual metallic sulphides (supposing only one of these to be present) is as follows:—

1. Those of silver (Ag₂S) and mercury (Hg₂S) yield sulphur dioxide gas and metal; in the case of silver, sulphate is formed at low temperatures. Metallic mercury, in the circumstances, goes off as a vapour, which is collected and condensed; silver remains as a regulus, but the sulphide of mercury is volatilized.

2. Sulphides of iron and zinc yield the oxides Fe₃O₄ and ZnO as final products, some basic sulphate being formed at the earlier stages, especially in the case of zinc. The oxides can be reduced by carbon. In the case of iron, the sulphide is converted into a mixture of oxide and normal sulphate, the latter one of oxide and basic sulphate. Sulphate of lead is stable at a red heat, sulphate of copper acid is oxidized to one or more sulphur dioxide and oxygen. In practice, neither oxidation process is used. The lead is oxidized as soon as the mixture of roasting-product and unchanged sulphide contains oxygen and sulphur in the ratio of O₂:S. The access of air is then stopped and the metal reduced, when the whole of the sulphur and oxygen is eliminated. This method is largely utilized in the smelting of lead from galena and of copper from copper pyrites.

3. Arsenic. The arsenic of arsenopyrites, when roasted in air, is converted into a kind of alloy of sulphide and oxide; the same holds for iron, only its oxysulphide is quite readily converted into the pure oxide Fe₂O₃ by further roasting. Oxysulphide of antimony, by suitable processes can be reduced to metal, but these processes are complicated, and the arsenic is largely recovered as the same end is far more easily obtained by precipitation, i.e., withdrawing the sulphur by fusion with metallic iron, forming metallic antimony and sulphide of iron. Both products fuse, but readily, partly, because fused antimony is far heavier than fused sulphide of iron. A precisely similar method is used occasionally for the reduction of lead from galena. Sulphide of lead, when fused, forms with metallic iron a fusible mixture (Fe₂Pb) which yields a regulus (=Pb) and a "mat" FeS, which, however, on cooling, decomposes into the ordinary sulphide FeS and finely divided iron. The latter has been supposed, with the formation of a new metallic proposition: Any one of the metals, copper, tin, zinc, lead, silver, antimony, arsenic, in general, is capable of desulphurizing (at least partially) any of the others that follows it in the metallic series. This action is just given as being the more rapid the greater the number of intervening terms. Hence, supposing a complete mixture of these metals to be melted down under circumstances admitting of only a partial sulphurization of the whole, the copper has the best chance of passing into the "mat," while the arsenic is the first to be eliminated as such, or, in the presence of oxidants, as oxide.

Arsenides.—Although arsenides are amongst the commonest impurities of ores generally, ores consisting essentially of arsenides are comparatively rare. The most important are certain double arsenides of cobalt and nickel, which in practice are always con- cerned, and which with other double arsenides of cobalt and nickel, such as iron, manganese, &c. The general mode of working these ores is as follows. The ore is first roasted by itself, when a part of the arsenic goes off as such and as oxide, while a complex of lower arsenic remains. The residue contains a mixture of metallic arsenic in fusion in the presence of some solvent for metallic bases. The effect is that the several metals are oxidized away and pass into the slag, where each metal is oxidized to a slag, which contains only cobalt and nickel; and at any stage the as yet unoxidized residue of arsenic assumes the form of a fused regulus, which sinks down through the slag as a "speiss." (This term has the same meaning in reference to arsenides as it has for metallic arsenic.) But, of course, using steel Crucibles, or in the case of nickel, and a slag which substantially is one of cobalt only. The composition of the speiss generally varies from As₄Co to As₄Co₃Ni, where

\[ 1 \leq x \leq 4 \]

Me" means one atomic weight of metal in 100, so that in general

\[ 1 \leq x \leq 4 \]

Metallurgy: General Sequence of Operations.—Occasionally, but rarely, metal is obtained in practical pure compact masses, from which the accompanying matrix or "gangue" can be detached by hand and hammer. In most cases the "ore" (see MINERAL DEPOSITS; VEINS) as it comes out of the mine or quarry, is simply a mixture of ore proper and gangue, in which the latter not unfrequently predominates. Hence it is generally necessary to purify the ore before the liberation of the metal is attempted. Most metallic ores are specifically heavier than the accompanying impurities and their purification is generally effected by reducing the crude ore to a fine enough powder to detach the metallic from the earthy part, and then washing away the latter by a current of water, as far as possible (see ORE-DRESSING).

The majority of ores being chemical compounds, the extraction of their metals demands chemical treatment. The chemical operations involved may be classified as follows:

1. Fiery Operations.—The ore, generally with some "flux," is exposed to the action of fire. The fire in most cases has a chemical, in addition to its physical, function. Moreover the furnace (q.v.) is designed so as to facilitate the action of the heat and furnace gases in the desired direction. It is intended either to burn a certain component of the ore—in which case it must be so regulated as to contain a sufficient excess of unburned oxygen; or it is meant to deoxidize ("reduce") the ore, when the draught must be restricted so as to keep the fire constantly wrapped up in combustible flame gases (carbon monoxide, hydrogen, marsh-gas, &c.). The majority of the chemical operations of metallurgy fall into this category, and in these processes other metal-reducing agents than those naturally contained in the fire (or blast) are only exceptionally employed.

2. Amalgamation.—The ore by itself (if it is a reguline one), or with certain reagents (if it is not), is worked up with mercury so that the metal is obtained as an amalgam, which can be distilled mechanically from the croos. The purified amalgam is distilled, when the mercury is recovered as a distillate while the metal remains.

3. Wet Processes.—Strictly speaking, certain amalgamation methods fall under this head; but, in its ordinary acceptance, the term refers to processes in which the metal is extracted either from the natural ore, or from the ore after roasting or other preliminary treatment, by an acid or salt solution, and from this solution precipitated—generally in the regline form—by some suitable agent.

Few methods of metal extraction at once yield a pure product. What as a rule is obtained is a more or less impure metal, which requires to be "refined" to become fit for the market.

Chemical Operations.—Amalgamation and wet-way processes have limited applications, being practically confined to copper, gold and silver. We therefore here confine ourselves, in the main, to pyrometallurgical operations.

The method to be adopted for the extraction of a metal from its ore is determined chiefly, though not entirely, by the nature of the non-metallic component with which the metal is combined. The simplest method of the regular kind is to use as the reducing agent, such as iron, one of the alkali metals, or one of the alkali earth metals, as lead, or a mixture of these. The residue consists of an impure oxide of the respective metal, which in all cases is reduced by treatment with fuel at a high temperature. Should the metal be present as a silicate, lime must be added in the smelting to remove the silicate, and the whole cooled with condensers. In all the other cases the reduction is effected in the fire itself, a tower-shaped blast furnace being preferably used. The furnace is charged with alternate layers of fuel and ore (or rather ore and flux, see below), and the whole kindled

cobalt is utilized as a blue pigment called "satin"; the nickel-selpe is worked up for metal.

Minor Reagents.—Besides the oxidizing and reducing agents present in the flux and the slags, various minor reagents may be noticed. Metallic iron as a desulfurizer has already been referred to. Oxide of lead, PbO (leaden oxide), is largely used as an oxidizing agent. At the point where it melts, it readily reacts with the重组 product, and, if the lead is insufficient for a complete oxidation, a "mat" comprising the more readily sulfurizable metals. Oxide of lead is the most powerful solvent for metallic oxides generally, and is also largely used for the separation of silver or gold from basic metallic oxides.

Metallic lead is to metals generally what oxide of lead is to metallic oxides. It accordingly is available as a solvent for taking up small particles of metal diffused throughout a mass of slag, and uniting them into one regulus. This leads us to the process of "cupellation," which serves for the extraction of gold, silver, &c.; see also Chapter 9 for uses from but with metals.

Fluxes.—All ores are contaminated with more or less gangue, which in general consists of infusible matter, and if left unheated in the furnace under the influence of the general heat, the ore would retain or lose less of the metal disseminated through it, or at best foul the furnace. To avoid this, the ore as it goes into the furnace is mixed with "fluxes" so selected as to convert the gangue into a fusible slag, which, when it melts, readily melts with the slag, and separates from the latter. The quality and proportion of flux should, if possible, be so chosen that the formation of the slag takes place without the ore being broken; or, in other words, that the basic oxide of the metal to be extracted may be dissolved by the slag, and its reduction thus be prevented or retarded. Slags are not a necessary evil; if an ore were free from gangue we should add flux to the furnace without producing a slag, but the result of its functions is to form a layer on the regulus which protects it against the further action of the blast or furnace gases. Fluxes may be arranged under the heads of (1) fluorspar, (2) basic fluxes, (3) acid fluxes.

Fluorspar fuses up at a red heat with silica, sulphates of calcium and barium, and a few other fusible substances into homogeneous masses. It shows little tendency to dissolve basic oxides, such as lime, &c. One part of fluorspar liquefies about half a part of silica, four parts of calcium sulphate and one and a half parts of barium sulphate. Upon these facts its extremely wide application in metallurgy is founded. Carbonate of soda (or potash) is the most powerful basic flux. It dissolves silica and all silicates into fusible glasses.

On the other hand, borax may be taken as a type for the acid fluxes. At a red heat, when it forms a viscous fluid, it readily dissolves almost all the gangue that has been brought to the furnace by the ore. A gangue of an ore in general consists either of some basic material such as carbonate of lime (or magnesia), ferric oxide, alumina, &c., or of some acid material such as the silicate, oxide, or sulphate of a mixture of the two classes of bodies. So any kind of gangue might be liquefied by means of borax or by means of alkaline carbonate; but neither of the two is used otherwise than for assaying; what the metal-smelter does is to add to a basic gangue the proportion of silica, and to an acid one the proportion of lime, or, indirectly, of ferrous or perhaps manganous oxide, which it may need for the formation of a slag of the proper qualities. The slag must possess the proper degree of saturation. In other words, taking $SiO_2 + nMeO$ (where MeO means an equivalent of base) as a formula for the potential slag, $n$ must have the proper value. If $n$ is too small, i.e., the slag is too acid, it may dissolve part of the metal and be recovered; if $n$ is too great, i.e., the slag too basic, it may refuse to dissolve, for instance, the ferrous oxide which is meant to go into it, and this oxide will then be reduced, and its metal (iron in our example) will pass into the regulus. In reference to this latter point, it is worth noting that oxides of lead and copper are more readily reduced to metals than oxide of iron FeO, is to FeO, the latter more readily to FeO than FeO itself to metal, and FeO more readily to metal than manganese oxide is. Oxide of calcium (lime) is not reducible at all. The order of basicity in the oxides (their readiness to go into the slag) is precisely the reverse.

Metal-Silicates.——These are the least understood, the most important problem of scientific metallurgy to determine the relations in this class of bodies between chemical composition on the one hand and fusibility and solvent power for certain oxides (CaO, FeO, PbO, &c.) on the other. In general expression, the formula $Mx+y$ may be expressed as $n(MO+xSiO)_{y}+(1-c)MeO+ySiO$ ($M$ = Ca, Mg, Fe, K, &c.; $c$ = $Fe/Fe + al/3Al$). The following nomenclature is in use: silicates as isomorphous, silicates as orthosilicates, silicates as metal-silicates, Class I. as sesquisilicates. In the formula $M$ stands for $Kg, Ca, Fe, &c.,$ or for $al = 3Al, fe = Fe + Fe, &c.$

It should be possible to represent each quality of a silicate as a function of the proportion of the nature of the individual bases that make up the MO and (fe or al) $O$ respectively. Our actual knowledge falls far short of this possibility. The problem, in fact, is very difficult, the more so as it is complicated by the existence of aluminates, compounds of silica, in which the silica is combined as a part or the whole of the acid, and the occasional existence of compounds of fluorides and silicates in certain slags. The formation of silts, or, what comes to the same thing, of the "regulus" of smelting, was especially studied by Percy, Smith, Bischof, Plattern and others in the laboratory of Voigt, Doelter, and at the Geophysical laboratory of the Carnegie Institution, Washington.

METAL-WORK. Among the many stages in the development of primate man, none can have been of greater moment in his struggle for existence than the discovery of the metals, and the means of working them. The names generally given to the three prehistoric periods of man's life on the earth—the Stone, the Bronze, and the Iron age—imply the vast importance of the progressive steps from the flint knife to the bronze chisel, and to the keen-edged elastic iron weapon or tool.

The metals chiefly used in the arts have been gold, silver, copper and tin (the last two generally mixed, the alumina phase called bronze), iron and lead (see the separate articles on these metals). Their peculiarities have naturally marked out each of them for special uses and methods of treatment. The durability and the extraordinary ductility and pliancy of gold, its power of being subdivided, drawn out or flattened into wire or leaf of almost infinite fineness, have led to its being used for works where great minuteness and delicacy of execution were required; while its beauty and rarity have, for the most part, limited its use to objects of adornment and luxury, as distinct from those of utility. In a less degree, most of the qualities of gold are shared by silver, and consequently the treatment of these two metals has always been very similar, though the greater abundance of the latter metal has allowed it to be used on a larger scale and for a greater variety of purposes. The great fluidity of bronze when melted, the slightness of its contraction on solidifying, together with its density and hardness, make it especially suitable for casting, and allow of its taking the impress of the mould with extreme sharpness and delicacy. In the form of plate it can be tempered and annealed till its elasticity and toughness are much increased, and it can then be formed into almost any shape under the hammer and punch. By other methods of treatment, known to the ancient Egyptians, Greeks and others, but now forgotten, it could be hardened and formed into knife and razor edges of the utmost keenness. In many specimens of ancient bronze, small quantities of silver, lead and zinc have been found, but their presence is probably accidental. In modern times brass has been much used, chiefly for the sake of its cheapness as compared with bronze. In beauty, durability and delicacy of surface it is very inferior to bronze, and, though of some commercial importance, has been of but little use in the production of works of art. To some extent, however, it is used in an alloy with tin, and is a material frequently employed in the surburban medieval times, especially from the 12th to the 15th century, mainly for objects of ecclesiastical use, such as pyxes, monstrances, reliquaries and crosiers, partly on account of its softness under the tool, and also because it was slightly easier to apply enamel and gilding to pure copper than to bronze (see fig. 1). In the medieval period it was used to some extent in the shape of thin sheeting for roofs, as at St Mark's, Venice; while during the 16th and 17th centuries it was largely employed for ornamental domestic vessels of various sorts.
Iron.—The abundance in which iron is found in so many places, its great strength, its remarkable ductility and malleability in a red-hot state, and the ease with which two heated surfaces of iron can be welded together under the hammer combine to make it specially suitable for works on a large scale where strength with lightness are required—things such as screens, window-grills, ornamental metal work, and the like. In bronze, hot plastic state iron can be formed and modelled under the hammer to almost any degree of refinement, while its great strength allows it to be beaten out into leaves and ornaments of almost paper-thinness and delicacy. With much practice it can be drawn out, drawing out and annealing, it gains much in strength and toughness, and the addition of a very minute quantity of carbon converts it into steel, less tough, but of the keenest hardness. The large employment of cast iron is comparatively modern, in England at least only dating from the 16th century; it is not, however, incapable of artistic treatment if due regard be paid to the necessities of casting, and if no attempt is made to imitate the fine-drawn lightness to which wrought iron so readily lends itself. At the best, however, it is not generally suited for the finest work, as the great contraction of iron in passing from the fluid to the solid state renders the cast somewhat blunt and spiritless.

Among the Assyrians, Egyptians and Greeks the use of iron, either cast or being the favourite metal almost for all purposes. The difficulty of smelting the ore was probably one reason for this, as well as the now forgotten skill which enabled bronze to be tempered to a steel-like edge. It had, however, its value, of which a proof occurs in Homer (II. xxiii.), where a mass of iron is mentioned as being one of the prizes at the funeral games of Patroclus.

Methods of Manipulation in Metal-Work.—Gold, silver and bronze may be treated in various ways, the chief of which are: (1) casting in a mould, and (2) treatment by hammering and punching (Fr. répoussé).

The first of these, casting is chiefly adapted for bronze, or 'Analyses of the iron of prehistoric weapons have brought to light the interesting fact that many of these earliest specimens of iron manufacture contain a considerable percentage of nickel. This special alloy does not occur in any known ores, but is invariably found in meteoric iron. It thus appears that iron was manufactured from meteorites which had fallen to the earth in an almost pure metallic state, possibly long before prehistoric man had learnt how to dig for and smelt iron in any of the forms of ore which are found on this planet.

in the case of the more precious metals only if they are used on a very small scale. The reason of this is that a répoussé relief is of much thinner substance than if the same design were cast, even by the most skilful metal-worker, and so a large surface may be produced with a very small expenditure of valuable metal. Casting is probably the most primitive method of metal-work. This has passed through three stages, the first being represented by solid castings, such as are most cells and other implements of the prehistoric time; the mould was formed of clay, sand or stone, and the fluid metal was poured in. The hollow was full. The next stage was to invent a way of saving much trouble and probably to save needless expenditure of the more valuable metal. The British Museum possesses an interesting Etruscan or Archaic Italian example of this primitive device. It is a bronze statuette from Sessa on the Voltorno, about 2 ft. high, of a female standing, robed in a close-fitting chiton. The presence of the iron core has been made visible by the splitting of the figure, owing to the unequal contraction of the two metals. The forearms, which are extended, have been cast separately and soldered or brazed on to the elbows. The third stage is that of the art of casting, in which, instead of a core, generally of clay, round which the metal was cast in a mere skin, only thick enough for strength, without waste of metal. The Greeks and Romans attained to the greatest possible skill in this process. Their exact method is not certainly known, but it appears probable that they were acquainted with the process now called à cire perdue—the same as that employed by the great Italian artists in bronze. Cellini, the great Florentine artist of the 16th century, has described it fully in his Trattato della Scultura. If a statue was to be cast, the figure was first roughly modelled in clay—only rather smaller in all its dimensions than the future bronze; all even this skin of wax was laid, and worked by the sculptor with modelling tools to the required form and finish. A mixture of pounded brick, clay and ashes was then ground finely in water to the consistence of cream, and successive coats of this mixture were then applied with a brush, till a second skin was formed all over the wax, fitting closely into every line and depression of the modelling. Soft clay was then carefully laid on to strengthen the mould, in considerable thickness, till the whole statue appeared like a shapeless mass of clay, round which iron hoops were bound to hold it all together. The whole was then thoroughly dried, and placed in a hot oven, which baked the clay, both of the core and the outside mould, and melted the wax, which was allowed to run out from small holes made for the purpose. Thus a hollow was left, corresponding to the skin of wax between the core and the mould, the relative positions of which were preserved by various small rods of bronze, which had previously been driven through from the outer mould to the rough core. The mould was now ready, and melted bronze was poured in till the whole space between the core and the outer mould was full. After slowly cooling, the outer mould was broken away from outside the statue and the inner core as much as possible broken up and raked out through a hole in the foot or some other part of the statue. The projecting rods of bronze were then cut away, and the whole finished by rubbing down and polishing over any roughness or defective places. The most skilful sculptors, however, had but little of this after-touching to do, the final modelling and even polish which they had put upon the wax being faithfully reproduced in the bronze casting. The further enrichment of the object by enamels and inlay of other metals was practised at a very early period by Assyrian, Egyptian and Greek metal-workers, as well as by the artists of Persia and medieval Europe.

The second chief process, that of hammered work (Gr. σφυρήσις; Fr. répoussé), was probably adopted for bronze-work on a large scale before the art of forming large castings was discovered. In the most primitive method thin plates of bronze were hammered over a wooden core, rudely cut into the required shape, the core serving the double purpose of giving shape to and strengthening the thin metal. A further development in the art of hammered work consisted in laying the metal plate on a soft
and elastic bed of cement made of pitch and pounded brick. The design was then beaten into relief from the back with hammers and punches, the pitch bed yielding to the protuberances which were thus formed, and serving to prevent the punch from breaking the metal into holes. The pitch was then melted away from the front of the embossed relief, and applied in a similar way to the back, so that the modelling could be completed on the face of the relief, the final touches being given by the graver. This process was chiefly applied by medieval artists to the precious metals, but by the Assyrians, Greeks and other early nations it was largely used for bronze. The great gates of Shalmaneser II., 858-823 B.C., from Balawat, now in the British Museum, are a remarkable example of this sort of work on a large scale, though in the neighbourhood of the casted tin and copper mines, which have been worked from a very early period. The use of lead has been more extended. In sheets it forms the best of all coverings for roofs and even spires. In the Roman and medieval periods it was largely used for coffins, which were often richly ornamented with cast work in relief. Though fusible at a very low temperature, and very soft, it has great power of resisting decay from damp or moisture. Its most important use in artistic form has been in the shape of baptismal fonts, chiefly between the 11th and the 14th centuries. The superior beauty of colour and durability of old specimens of lead is owing to the natural presence of a small proportion of silver. Modern smelters carefully extract this silver from the lead ore, thereby greatly impairing the durability and beauty of the metal.

As in almost all the arts, the ancient Egyptians excelled in their metal-work, especially in the use of bronze and the precious metals. These were worked by casting and hammering, and ornamented by inlay, gilding and enamels with the greatest possible skill. From Egypt perhaps was derived the early skill of the Hebrews. Further instruction in the art of metal-working came probably to the Jews from the neighbouring country of Tyre. The description of the great gold lions of Solomon's throne, and the layer of cast bronze supported on figures of oxen, shows that the artificers of that time had overcome the difficulties of metal-working and founding on a large scale. The Assyrians were perhaps the most remarkable of all ancient nations for the colossal size and splendour of their works in metal; whole circuit walls of great cities, such as Nineveh and Babylon, were sometimes covered with metal plates, gilt or silvered. Herodotus, Athenaeus and other Greek and Roman writers have recorded the enormous number of colossal statues and other works of art for which Babylon and Nineveh were so famed. The numerous objects of bronze and other metals brought to light by the excavations in the Tigris and Euphrates valleys, though mostly on a small scale, bear witness to the great skill and artistic power of the people who produced them; while the discovery of some bronze statuettes, shown by inscriptions on them to be not later than 2200 B.C., proves how early was the development of this branch of art among the people of Assyria.

The Metal-Work of Greece.—The early history of metal-working in Greece is extremely obscure, and archaeologists are divided in opinion even on so important a question as the relative use of bronze and iron in the Homeric age. The evidence of Mycenaean remains, as compared with the literary evidence of Homer, is both inadequate and inconclusive (see AEGEAN CIVILIZATION; GREEK ART; ARMIS AND ARMOUR, Ancient; PLATE; &c.). The poems of Homer are full of descriptions of elaborate works in bronze, gold and silver, which, even when full allowance is made for poetic licence, show how advanced both in working and ornamenting of these metals. Homer's description of the shield of Achilles, made of bronze, enriched with bands of figure reliefs in gold, silver and tin, could hardly have been written by a man who had not some personal acquaintance with works in metal of a very elaborate kind. Again, the accuracy of his descriptions of brazen houses—such as that of Alcmenes, Od. vii. 81—bore witness to by Pausanias's mention of the bronze temple of Athena Λακκας in Sparta, and the bronze chamber dedicated to Myron in 648 B.C., as well as by the discovery of large faces and bronze nails, which show that the whole interior of the so-called temple of Attreus at Mycenae was once covered with a lining of bronze plates. Of the two chief methods of working bronze, gold and silver, it is probable that the hammer process was first practised, at least for statues, among the Greeks, who themselves attributed the invention of the art of hollow casting to Theodorus and Rheocus, both Samian sculptors, about the middle of the 6th century B.C. Pausanias especially mentions that one of the oldest statues he had ever seen was a large figure of Zeus in Sparta, made of hammered bronze plates riveted together. With increased skill in large castings, and the discovery of the use of copper and brass, the art is said to have been carried into a mere skin-like cavity, hammered or repoussé work was only used in the case of small objects in which lightness was
METAL-WORK

desirable, or for the precious metals in order to avoid large expenditure of metal. The colossal statues of ivory and gold by Phidias were the most notable examples of this use of gold, especially his statue of Athena in the Parthenon, and the one of Zeus at Olympia. The nude parts, such as face and hands, were of ivory, while the armour and drapery were of beaten gold. The comparatively small weight of gold used by Phidias is very remarkable when the great size of the statues is considered.

A graphic representation of the workshop of a Greek sculptor in bronze is given on a fictive vase in the Berlin Museum (see Gerhard's *Trinkschalen*, plates xii., xiii.). One man is raking out the fire in a high furnace, while another behind is blowing the bellows. Two others are smoothing the surface of a statue with scraping tools, formed like a stripl. A fourth is beating the arm of an unfinished figure, the head of which lies at the workman's feet. Perhaps the most important of early Greek works in cast bronze, both from its size and great historical interest, is the bronze pillar (now in the Hippodrome at Constantinople) which was erected to commemorate the victory of the allied Greek states over the Persians at Plataea in 479 B.C. (see Newton's *Travels in the Levant*). It is in the form of three serpents twisted together, and before the heads were broken off was at least 20 ft. high. It is cast hollow, all in one piece, and has the names of the allied states engraved on the lower part of the coils. Its size and the beauty of its surface show great technical skill in the founder's art. On it once stood the gold tripod dedicated to Apollo as a tenth of the spoils. It is described by both Herodotus and Pausanias.

Marble was comparatively but little used by the earlier Greek sculptors, and even Myron, a rather older man than Phidias, seems to have executed nearly all his most important statues in metal. Additional richness was given to Greek bronze-work by gold or silver inlay on lips, eyes and borders of the dress; one remarkable statuette in the British Museum has eyes inlaid with diamonds and fret-work inlay in silver on the border of the chiton. The mirrors of the Greeks are among the most important specimens of their artistic metal-work. These are bronze disks, one side polished to serve as a reflector, and the back ornamented with engraved outline drawings, often of great beauty (see Gerhard, *Etruskische Spiegel*, 1843-1867). In metal-work, as in other arts, the Romans were pupils and imitators of the Greeks. Owing to the growth of the spirit of luxury, a considerable demand arose for magnificent articles of gold and silver plate. The finest specimens of these that still exist are the very beautiful set of silver plate found buried near Hildeshim in 1869, now in the Berlin Museum. They consist of drinking vessels, bowls, vases, ladles and other objects of silver, parcel-gilt, and exquisitely decorated with figures in relief, both cast and repoussé. There are electrotypes of these in the Victoria and Albert Museum. When the seat of the empire was changed, Byzantium became the chief centre for the production of artistic metal-work. From Byzantium the special skill in this art was transmitted in the 9th and 10th centuries to the Rhenish provinces of Germany and to Italy, and thence to the whole of western Europe; in this way the 18th century smith who wrought the Hampton Court iron gates was the heir to the mechanical skill of the ancient metal-workers of Phoecinia and Greece. In that period of extreme degradation into which all the higher arts fell after the destruction of the Roman Empire, though true feeling for beauty and knowledge of the subtleties of the human form remained for centuries almost dormant, yet Byzantium at least there still survived great technical skill and power in the production of all sorts of metal-work. In the age of Justinian (first half of the 6th century) the great church of St Sophia at Constantinople was adorned with an almost incredible amount of wealth and splendour in the form of screens, altars, candlesticks and other ecclesiastical furniture made of massive gold and silver.

Metal-Work in Italy.—It was therefore to Byzantium that Italy turned for metal-workers, and especially for goldsmiths, when, in the 6th to the 8th centuries, the basilica of St Peter's in Rome was enriched with masses of gold and silver for decorations and fittings, the gifts of many donors from Belisarius to Leo III., the mere catalogue of which reads like a tale from the *Arabian Nights*. The gorgeous Palæa d'oro, still in St Mark's at Venice, a gold retable covered with delicate reliefs and enriched with enamels and jewels, was the work of Byzantine artists during the 11th century. This work was in progress for more than a hundred years, and was set in its place in 1106 A.D., though still unfinished (see Bellomo, *Palæa d'oro di S. Marco*, 1847). It was, however, especially for the production of bronze doors for churches, ornamented with panels of cast work of high relief, that Italy obtained the services of Byzantine workmen (see Garrucci, *Arte cristiana*, 1872-1882). One artist, named Staurachios, produced many works of this class, some of which still exist, such as the bronze doors of the cathedral at Amalfi, dated 1066 A.D. Probably by the same artist, though his name was spelled differently, were the bronze doors of San Paolo fuori le Mura, Rome, careful drawings of which exist, though the originals were destroyed in the fire of 1824. Other important examples exist at Ravello (1109), Salerno (1095), Amalfi (1062), Atrani (1087); and doors at Monreale in Sicily and at Trani, signed by an artist named Barisanos (end of the 12th century); the reliefs on these last are remarkable for expression and dignity, in spite of their early rudeness of modelling and ignorance of the human figure. Most of these works in bronze were enriched with fine lines inlaid in silver, and in some cases with a kind of niello or enamel. The technical skill of these Byzantine metal-workers was soon acquired by native Italian artists, who produced many important works in bronze similar in style and execution to those of the Byzantine Greeks. Such, for example, are the bronze doors of San Zeno at Verona (unlike the others, of repoussé not cast work); those of the Duomo of Pisa, cast in 1180 by Bonannus, and of the Duomo of Troia, the last made in the beginning of the 12th century by Oderius of Benevento. Another artist, named Roger of Amalfi, worked in the same way; and in the year 1219 the brothers Hubertus and Petrus of Placenza cast the bronze door for one of the side chapels in San Giovanni in Laterano. One of the most important early specimens of metal-work is the gold and silver altar of Sant' Ambrogio in Milan. In character of work and design it resembles the Venice Palæa d'oro, but is still earlier in date, being a gift to the church from Archbishop Angilbert II. in 835 A.D. (see Du Sommerard, and D'Agincourt, *Moyen Âge*). It is signed volvenivs magister phaber; nothing is known of the artist, but he probably belonged to the semi-Byzantine school of the Rhine provinces; according to Dr Rock he was an Anglo-Saxon goldsmith. It is a very sumptuous work, the front of the altar being entirely of gold, with repoussé reliefs and cloisonné enamels; the back and ends are of silver, with gold ornaments. On the front are figures of Christ and the twelve apostles; the ends and back have reliefs illustrating the life of St Ambrose.

The most important existing work of art in metal of the 13th century is the great candelabrum now in Milan Cathedral. It is of gilt bronze, more than 14 ft. high; it has seven branches for
candles, and its upright stem is supported on four winged dragons. For delicate and spirited execution, together with refined gracefulness of design, it is unsurpassed by any similar work of art. Every one of the numerous little figures with which it is adorned is worthy of study for the beauty and expression of the face, and the dignified arrangement of the drapery (see fig. 3). The semiconvexional open scroll-work of branches and fruit which wind around and frame each figure or group is devised with the most perfect taste and richness of fancy, while each minute part of this great piece of metal-work is finished with all the care that could have been bestowed on the smallest article of gold jewellery. Though something in the grotesque dragons of the base recalls the Byzantine school, yet the beauty of the figures and the keen feeling for graceful curves and folds in the drapery point to a native Italian as being the artist who produced this wonderful work of art. There is a cast in the Victoria and Albert Museum.

During the 13th and 14th centuries in Italy the widespread influence of Niccola Pisano and his school encouraged the sculptor to use marble rather than bronze for his work. At this period wrought iron came into general use in the form of screens for chapels and tombs, and grills for windows. These are mostly of great beauty, and show remarkable skill in the use of the hammer, as well as power in adapting the design to the requirements of the material. Among the finest examples of this sort of work are the screens round the tombs of the Scala family at Verona, 1330–1375,—a sort of network of light cusped quatrefoils, each filled up with a small ladder (scala) in allusion to the name of the family. The most elaborate specimen of this wrought work is the screen to the Rinuccini chapel in Santa Croce, Florence, of 1371,—in which moulded pillars and window-like tracery have been wrought and modelled by the hammer with extraordinary skill (see Wyatt, Metal-Work of Middle Ages). Of about the same date are the almost equally magnificent screens in Sta Trinita, Florence, and at Siena across the chapel in the Palazzo Pubblico. The main part of most of these screens is filled in with quatrefoils, and at the top is an open frieze formed of plate iron pierced, repoussé, and enriched with engraving. In the 14th century great quantities of objects for ecclesiastical use were produced in Italy. The silver altar of the Florence baptistery was begun in the first half of the 14th century, and not completed till after 1473 (see Gaz. des beaux-arts, Jan. 1883). The greatest artists in metal laboured on it in succession, among them Orcagna, Ghiberti, Verrocchio, Ant. Pollaiuolo and many others. It has elaborate reliefs in repoussé work, cast canopied and minute statuettes, with the further enrichment of translucent coloured enamels. The silver altar and reliquary of Pistoia Cathedral (see fig. 4), and the great shrine at Orvieto, are works of the same class, and of equal importance.

Whole volumes might be devoted to the magnificent works in bronze produced by the Florentine artists of this century, works such as the baptistery gates by Ghiberti, the statues of Verrocchio, Donatello and many others, the bronze screen in Prato cathedral by Simone, brother of Donatello, in 1444–1461, and the screen and bronze ornaments of the tomb of Piero and Giovanni dei Medici in San Lorenzo, Florence, by Verrocchio, in 1472. At the latter part of the 15th century and the beginning of the 16th the Pollaiuoli, Ricci and other artists devoted much labour to the production of candlesticks and smaller objects of bronze, such as door-knockers, many of which are works of the greatest beauty. The candlesticks in the Certosa near Pavia, and in the cathedrals of Venice and Padua, are the finest examples of these. Niccolò Grossi, who worked in wrought iron under the patronage of Lorenzo dei Medici, produced some wonderful specimens of metal-work, such as the candlesticks, lanterns, and rings fixed at intervals round the outside of the great palaces (see fig. 5). The Strozzi palace in Florence and the Palazzo del Magnifico at Siena have fine specimens of these—the former of wrought iron, the latter in cast bronze. At Venice fine work in metal, such as salvers and vases, was being produced, of almost Oriental design, and in some cases the work of resident Arab artisans. In the 16th century Benvenuto Cellini was supreme for skill in the production of enamelled jewellery, plate and even larger works of sculpture (see Flon's Ben. Cellini, 1882), and Giovanni de Bologna in the latter part of the same century inherited to some extent the skill and artistic power of the great 15th-century artists.

Spain.—From a very early period the metal-workers of Spain have been distinguished for their skill, especially in the use of the precious metals. A very remarkable set of specimens of goldsmith's work of the 7th century are the eleven votive crowns, two crosses and other objects found in 1538 at Guarrazar, and now preserved at Madrid and in Paris in the Cluny Museum (see Du Sommerard, Musée de Cluny, 1852). Magnificent works in silver, such as shrines, altar crosses and church vessels of all kinds, were produced in Spain from the 14th to the 16th century—especially a number of sumptuous tabernacles (cudotela) for the host, magnificent examples of which still exist in the cathedrals of Toledo and Seville. The bronze and wrought-iron screens—rejas, mostly of the 15th and 16th centuries—to be found in almost every important church in Spain are very fine examples of metal-work. They generally have moulded rails or balusters, and rich friezes of pierced and repoussé work, the whole being often thickly plated with silver. The common use of metal for pulpits is a peculiarity

![Fig. 4.—Silver Repoussé Reliefs from the Pistoia Retable.](image-url)
of Spain; they are sometimes of bronze, as the pairs in Burgos and Toledo cathedrals, or in wrought iron, like those at Zamora and in the church of San Gil, Burgos. The great candelabrum or *tenebrarium* in Seville Cathedral is the finest specimen of 16th-century metal-work in Spain; it was mainly the work of Bart. Morel in 1562. It is of cast bronze enriched with delicate scroll-work foliage, and with numbers of well-modelled statuettes. Especially in the art of metal-work Spain was much influenced in the 15th and 16th centuries by both Italy and Germany, so that numerous Spanish objects produced at that time owe little or nothing to native designers. At an earlier period Arab and Moorish influence is no less apparent.

![Fig. 6.—Part of the “Eleanor Grill.”](image1)

**England.—** In Saxon times the English metal-workers, especially of the precious metals, possessed great skill, and appear to have produced shrines, altar-frontals, retabes and other ecclesiastical furniture of considerable size and magnificence. Dunstan, archbishop of Canterbury (925-988), like Bernward, bishop of Hildesheim a few years later, and St Eloi of France three centuries earlier, was himself a skilful worker in all kinds of metal. The description of the gold and silver retable given to the high altar of Ely by Abbot Theodwin in the 11th century, shows it to have been a large and elaborate piece of work decorated with many reliefs and figures in the round. In 1241 Henry III. gave the order for the great gold shrine to contain the bones of Edward the Confessor. It was the work of members of the Otho family, among whom the goldsmith’s and coiner’s crafts appear to have been long hereditary. Countless other important works in the precious metals adorned every abbey and cathedral church in the kingdom. In the 13th century the English workers in wrought iron were especially skilful. The grill over the tomb of Queen Eleanor at Westminster, by Thomas de Leghton, made about 1254, is a remarkable example of skill in welding and modelling with the hammer (see fig. 6). The rich and graceful iron hinges, made often for small and out-of-the-way country churches, are a large and important class in the list of English wrought-iron work. Those on the refectory door of Merton College, Oxford, are a beautiful and well-preserved example dating from the 14th century. More mechanical in execution, though still very rich in effect; is that sort of iron tracery work produced by cutting out patterns in plate, and superimposing one plate over the other, so as to give richness of effect by the shadows produced by these varying planes. The screen by Henry V.’s tomb at Westminster is a good early specimen of this kind of work. The screen to Bishop West’s chapel at Ely, and that round Edward VI.’s tomb at Windsor, both made towards the end of the 15th century, are the most magnificent English examples of wrought iron; and much wrought-iron work of great beauty was produced at the beginning of the 18th century, especially under the superintendence of Sir Christopher Wren (see Ebbets, *Iron Work of 17th and 18th Centuries*, 1880). Large flowing leaves of acanthus and other plants were beaten out with wonderful spirit and beauty of curve. The gates from Hampton Court are the finest examples of this class of work (see fig. 7).

From an early period bronze and latten (a variety of brass) were much used in England for the smaller objects both of ecclesiastical and domestic use, but except for tombs and lecterns were but little used on a large scale till the 16th century. The full-length recumbent effigies of Henry III. and Queen Eleanor at Westminster, cast in bronze by the *cire perdue* process, and thickly gilt, are equal, if not superior, in artistic beauty to any sculptor’s work of the same period (end of the 13th century) that was produced in Italy or elsewhere. These

![Fig. 7.—Part of one of the Hampton Court Gates.](image2)
Germany.—Unlike England, Germany in the 10th and 11th centuries produced large and elaborate works in cast bronze, especially doors for churches, much resembling the contemporary doors made in Italy under Byzantine influence. Bernward, bishop of Hildesheim, 992–1022, was especially skilled in this work, and was much influenced in design by a visit to Rome in the suite of Otho III. The bronze column with winding reliefs now at Hildesheim was the result of his study of Trajan’s column, and the bronze door which he made for his own cathedral shows classical influence, especially in the composition of the drapery of the figures in the panels. The bronze doors of Augsburg (1047–1073) are similar in style. The bronze tomb of Rudolph of Swabia in Mersburg Cathedral (1080) is another fine work of the same school. The production of works in gold and silver was also carried on vigorously in Germany. The shrine of the three kings at Cologne is the finest surviving example. At a later time Augsburg and Nuremberg were the chief centres for the production of artistic works in the various metals. Hermann Vischer, in the 15th century, and his son and grandsons were very remarkable as bronze founders. The font at Wittenberg, decorated with reliefs of the apostles, was the work of the elder Vischer, while Peter and his son produced, among other important works, the shrine of St. Sebald at Nuremberg, a work of great finish and of astonishing richness of fancy in its design. The tomb of Maximilian I., and the statues round it, at Innsbruck, begun in 1521, are perhaps the most meritorious German work of this class in the 16th century, and show considerable Italian influence. In wrought iron the German smiths, especially during the 15th century, greatly excelled. Almost peculiar to Germany is the use of wrought iron for grave-crosses and sepulchral monuments, of which the Nuremberg and other cemeteries contain fine examples. Many elaborate well-canopies were made in wrought iron, and gave full play to the fancy and invention of the smith. The celebrated 15th-century example over the well at Antwerp, attributed to Quintin Matsys, is the finest of these.

France.—From the time of the Romans the city of Limoges has been celebrated for all sorts of metal-work, and especially for brass enriched with enamel. In the 13th and 14th centuries many life-size sepulchral effigies were made of beaten copper or bronze, and ornamented by various-coloured “champlevé” enamels. The beauty of these effigies led to their being imported into England; most are now destroyed, but a fine specimen still exists at Westminster on the tomb of William de Valence (1296). In the ornamental iron-work for doors the French smiths were pre-eminent for the richness of design and skilful treatment of their metal. Probably no examples surpass those on the west doors of Notre Dame in Paris—unhappily much falsified by restoration. The crockets and finials on the flèches of Amiens and Rheims are beautiful specimens of a highly ornamental treatment of cast lead, for which France was especially celebrated. In most respects, however, the development of
METAL-WORK

the various kinds of metal-working went through much the same stages as in England.

**17th and 18th Centuries.**—The metal-workers of the East, especially in brass and steel, were renowned for their skill even in the time of Theophilus, the monkish writer on the subject in the 12th century. But it was during the reign of Shah Abbas I. (d. 1628) that the greatest amount of skill both in design and execution was reached by the Persian workmen. Delicate pierced vessels of gilt brass, enriched by tooling and inlay of gold and silver, were among the chief specialties of the Persians (see fig. 9). A process called by Europeans “damascening” (from Damascus, the chief seat of the export) was used to produce vessels and rich armorial device. A pattern engraved on a metal blank with a graver in iron or steel, and then gold wire was beaten into the sunk lines, the whole surface being then smoothed and polished. In the time of Cellini this process was copied in Italy, and largely used, especially for the decoration of weapons and armour. The repoussé process both for brass and silver was much used by Oriental workers, and even now fine works of this class are produced in the East, old designs still being adhered to.

(J. H. M.)

**Art Metal-Work.**—The term “art metal-work” is applied to those works in metal in which beauty of form or decorative effect is the first consideration, irrespective of whether the object is intended for or is merely ornamental; and it embraces any article from a Birmingham brass bedstead to works of the highest artistic merit. The term, as defined, distinguishes one branch of metal-working from another, is objected to by many on the ground that no such prefix was required in the best periods of art, and that all crafts continued to do without it to the present day. Indeed, as long as metal-working remained a handicraft—in other words, until the introduction of steam machinery—every article, however humble its purpose, seems to have been endowed with some traditional beauty of form. The robust, florid and distinctly Roman rendering of the classic, which followed the refined and attenuated treatment associated with the architecture of the brothers Adam, who died in 1792 and 1794, is the last development in England which can be regarded as a national style. The massively moulded ormulu stair balustrade of Northumberland House, now at 49 Prince’s Gate; the candelabra at Windsor and Buckingham Palace, produced in Birmingham by the firm of Messenger; the cast-iron railings with jawnin heads and lictors’ faces, the tripods, Corinthian column standard lamps and candelabra, boat-shaped oil lamps and tent-shaped lustres with classic mountings, are examples of the metal-work of a style which, outside the eccentric Brighton Pavilion and excursions into Gothic and Elizabethan, was universally accepted in the United Kingdom from the days of the Regency until after the accession of Victoria. Except perhaps the silversmiths, no one was conscious of being engaged in “art metal-working,” yet the average is neither vulgar nor in bad taste, and the larger works are both dignified and suited to their architectural surroundings.

The introduction of gas as an illuminant, about 1816, at once induced a large demand and a novel description of metal fitting; and the craft fell under the control of a new commercial class, intent on breaking with past traditions, and utilizing steam power, electro-deposition, and every mechanical and scientific invention tending to economize metal or labour. But when all artistic perception in Great Britain appeared lost in admiration of the triumphs of machinery and the expansion of trades, a new influence in art matters, that of the Prince consort, began to make itself felt. The Great Exhibition, state-aided schools of design, the South Kensington Museum, and the establishment of a Science and Art Department under Government, were among the results of the important art revival which he inaugurated. He is credited with having himself designed candelabra and other objects in metal, and he directly encouraged the production of the sumptuous treatise on metal-work by Digby Wyatt, which laid the foundations of the revival. To this work, and that of Owen Jones, can be traced the origin of the eclecticism which has laid all past styles of art under contribution. The Gothic revival also helped the recognition of art, without very directly affecting the movement. It was valuable in teaching how to work within definite limitations, but without slavish copying; it also emancipated a considerable body of craftsmen from the tyranny of manufacturers whose sole idea was that machine-work should supersede handicraft. Its greatest efforts were the metal chancel-screen designed by Sir G. G. Scott, that for Hereford Cathedral having been exhibited in 1862. It does not appear that the influence either of Owen Jones or Digby Wyatt on metal-working extended beyond bringing the variety of past styles to the direct notice of designers. Neither can the London silversmiths, though they employed the best talent available, particularly in the decade following the Great Exhibition of 1851, be credited with much influencing the art metal revival. They were rivaled by Elkington of Birmingham, who secured the permanent assistance of at least one fine artist, Morel Ladeuil, the producer of the Elcho Challenge Shield. Perhaps the first actual designer to make a lasting impression on the crafts was Thomas Jeckyll, some of whose work, including gates for Sandringham, was exhibited at the Great Exhibition of 1851. His great rival as a designer was Alfred Stevens, whose influence on English craftsmen might be regarded as almost comparable to that of Michelangelo on that of his Italian contemporaries. Stevens’s designs certainly directly raised the standard of production in several metal-working firms by whom he was employed; whilst in the Wellington Memorial in St Paul’s Cathedral, and in Dorchester House, his work is seen unfettered by commercial considerations. Omitting many whose occasional designs have had little influence on the development of the metal crafts, we come to Alfred Gilbert, whose influence for a time was scarcely less than that of Stevens himself. Monumental works, such as his statue of Queen Victoria at Winchester and his work at Windsor, may be handed down as his greatest achievements, but judged as art metal-work, his smaller productions, such as the cenotaph presented by the army and navy to Queen Victoria on her Jubilee, have been more important.

The charming bronze statuettes of Onslow Ford, the most representative of which are in the Tate Gallery; the work of George Frampton, as seen in the Mitchell Memorial; and the large statuary of W. S. Gilbert, examples of which are the bronze gates of the Adelphi Bank at Liverpool, have all contributed, especially when applied to architectural decoration, to a high standard of excellence. Painters also have frequently designed and modelled for metal-work, for example, Lord Leighton, who produced bronze statuettes of most refined character; and Sir L. Alma-Tadema, who designed the grilles for his studio and entrance hall; but none so conspicuously as Professor H. von Herkomer, who, whether working in gold and enamel, iron, or his favourite alloy, pewter, infuses a freshness into his designs and methods which displays an unusual mastery over materials.

The gift of reproducing effects of nature or art by brush or chisel is not necessarily accompanied by power to design; but a noteworthy exponent of the dual faculty is G. C. Haïté, whose designs are widely applied.

It is chiefly to architecture that metal-work owes its permanent artistic improvement. In England buildings of Norman Shaw and Ernest George demanded quiet and harmonious metal-work; and the custom of these architects of superintending and designing every detail, even for interiors, created the supply. The work of every worthy architect raises the standards of the crafts; but beyond others Messrs Ashbee, Lethaby and Wilson have taken an active personal interest in schools of metal-work. The technical schools have also been of immense service in creating a class of self-respecting craftsmen, whose wages enable them to regard their work as worthy occupation absorbing in interest. Home industries such as the metal-working round Keswick (founded in 1884 by Canon and Mrs Rawnsley), executed during hours of idleness by field labourers and railway porters, educate the passer-by as well as the worker.
CAST BRONZE GATES, ADELPHI BANK, LIVERPOOL.
Designed by W. D. Caroe, the figures by Stirling Lee, executed by Starkie Gardner and Co.
METAL-WORK

RAIN-WATER HEAD, IN LEAD, FOR THE VICTORIA LAW COURTS, BIRMINGHAM,
Designed by Aston Webb and Ingres Bell, and executed by Dent and Hellier.

COVERED BRIDGE OF IRON, SHEATHED IN CAST LEAD, GRAND HOTEL, LONDON.
Designed by William Woodward, and executed by Starkie Gardner and Co.
British architects and artists who design for the principal decorating firms are to-day as conversant with the Renaissance and succeeding styles of France and Italy as medieval revivalists were familiar with the Gothic styles with which they made us so well acquainted. Metal-work more or less based upon every kind of past style is produced in vast quantities, and in some cases so skilful are the workers that modern forgeries and reproductions are almost beyond the power of experts to detect. This large class of designers and craftsmen, to whom a thorough knowledge of the history of design is a necessity, follows and develops traditional lines. The new art school, on the contrary, breaks wholly with tradition, unless unconsciously influenced by the Japanese, and awards the highest place to originality in design. It is not to be expected that an art-revival following on, and in possession of, all the results of a period of unprecedented activity in scientific research should proceed with the same restraint as heretofore; but the unfettered activity, and the general encouragement to abandon the traditions of art, have no exact parallel in the past, and may yet prove a danger. It is perhaps the very rapidity of the movement that is likely to retard its progress, and to fail to carry with it the wealthy clients and the decorators they employ, or perhaps even to increase the disposition to cling to the reproductions of the styles of the 17th and 18th centuries. The multiplication of art periodicals, lectures, books, photographs, meetings of societies and guilds, museums, schools of arts and crafts, polytechnics, scholarships, facilities for travel, exhibitions, even those of the Royal Academy, to which objects of applied art are now admitted, not only encourages many persons to become workers and designers in the applied arts, but exposes everything to the plagiarist, who travesties the freshest idea before it has well left the hands of its originator. Thus the inspirations of genius, appropriated by those who imperfectly appreciate their subtle beauty and quality, become hackneyed and lose their charm and interest. The keen desire to be unconventional in applied art has spread from Great Britain and the United States to Germany, Austria and other countries, but without well-defined first principles, or limitations. It seems agreed in a general way that the completed work in metal is to be wholly the conception and, as far as possible, the actual handiwork of the designer; casting by the cire-perdue process, left practically untouched from the mould, and embossing, being the two most favoured processes. The female figure is largely made use of, and rich and harmonious colours are sought, the glitter of metal being invariably subdued by deadening its lustre, or by patinas and oxides. Gilding, stains and lacquers, electro-plating, chasing, "matting," frosting, burnishing, mechanically produced mouldings and embossings, are the processes, with the result that the work of the present century, is disused and avoided. New contrasts are formed by the juxtaposition of differently toned metals; or these with an inlay of hollais shell, introduced by Alfred Gilbert; or of coloured wax, favoured by Onslow Ford; or enamelling, perfected by Professor von Herkomer; or stained ivory, pearls, or semi-precious stones. The quality of the surface left by the skilled artist or artisan is more regarded than symmetry of design, or even than correct modelling. Frequently only the important parts in a design are carefully finished and the rest merely sketched, the mode of working, whether by modelling-tool or hammer, being always left apparent. The newer kinds of art metal-work have, until recently, reached the purchaser direct from the producer's workshop; but they may now also be seen in the shops of smiths' merchants, jewellers, and general dealers, who are thus helping to transfer production from large commercial manufactories to smaller workshops under artistic control. The production of the larger household accessories, such as bedsteads, fenders, gas and electric fittings, clocks, &c., has hardly as yet come under the influence of the art movement. The services rendered by Mr. W. A. S. Benson, Chiswick, who commenced about 1886 to revolutionize the production of sheet-brass and copper utensils, cannot be passed over. The average ecclesiastical metal-work has rather receded than progressed in merit, except when designed by architects and executed under their supervision. Though the demand for good domestic wrought-iron work has enormously increased, adaptations from the beautiful work of the 17th and 18th centuries have been found so suited to their architectural surroundings, that new departures have been relatively uncommon. Of such the gates for Sandringham, by Jackyll; for Crewe Hall, by Charles Barry; and for the Victoria and Albert Museum, by Gamble, are the earliest and best known. Of the cast number designed upon traditional lines may be cited those for Lambton Castle, Welbeck, Eaton Hall, Twickenham, Cliveden, and the Astor Estate Office on the Victoria Embankment. Cast iron, brought to perfection by the Coalbrookdale Company about 1860, but now little esteemed, owing to the poverty of design which so often counterfeits smiths' work, presents great opportunities to founders possessing taste or will to submit to artistic control. A very large field is also opening for cast-lead work, whether associated with architecture, as in the leading covered-way over Northumberland Street, in London (see Plate), and the fine rain-water heads of the Birmingham Law Courts (see Plate), or with the revival of the use of metal statuary and vases in gardens. The subdued colour and soft contours of pewter render it once more a favoured material, peculiarly adapted to the methods of the art revival, and perhaps destined to supersede electro-plate for household purposes. In silver-work the proportion of new art designs exhibited by dealers and others is still relatively small; but jewelers, except when setting pure brilliants and pearls, are becoming more inclined to make their jewels of finely-modelled gold and enamelled enriched with precious and semi-precious stones, than of gems merely held together by wholly subordinate settings.

On the continent of Europe, France was the first to recognize the merits of its bygone designers and craftsmen, and even antecedent to the Exhibition of 1851, when art in Great Britain was dormant, it was possible to obtain in Paris faithful reproductions of the finest ormolu work of the 18th century. At the same time a most active production of modern designs was proceeding, stimulated by rewards, with the result that the supply of clocks, lamps, candelabra, statuettes, and other ornaments in bronze and zinc to the rest of Europe became a monopoly of Paris for nearly half a century. In all connected with their own homes the French adhere to their traditions far more than other nations, and the attempt at originality in the introduction of metal-work in the scheme of decoration of a room is almost unknown. In the domain of bronze and imitation bronze statuary the originality of the French is absolutely unrivalled. And not only in bronze, but in Paris jewellery, they are becoming more inclined to make their jewels of finely-modelled gold and especially enriched with precious and semi-precious stones, than of gems merely held together by wholly subordinate settings.
METAL-WORK

and to Russia, where, having little artistic past to refer to, designers and craftsmen display unequalled individuality and freedom. It is from the French Far East that the metal-work of China and Japan, so pleasantly naive and inexpensive, though becoming undeniably modified as to design through contact with European buyers, is losing none of its matchless technique, which indeed in Japan is still being developed. In any history of the art revival the influence of such firms as Barbedienne and Christoffle in Paris and Tiffany in New York cannot be ignored.

J. S. G.

**Industrial Metal-Work.**

The malleability and ductility of metals lie at the basis of the work of the gold- and silver-smiths at one extreme, and of the boiler-maker at the other. Sheet metals can be made to assume almost any shape under the hammer, or by pressure, and in such a way that the whole of the surface is compressed uniformly in every direction. The more awkward shapes, involving excessive extensions of metal, are produced by drawing processes between dies of iron and steel in power presses. All the common domestic utensils in tinned and enamelled ware, and all the ordinary patterns of the silversmiths, are similarly done. Frequent annealings are necessary to prevent fracture of the metal; but with these and the observance of certain other precautions the characteristic malleable character of metals is of the utmost importance. Another illustration of the malleability of metal is afforded by metal spinning. A sheet of metal set revolving at a high speed on a mandrel bent or shaped to the form of the numerous mouldings, by a blunt hardened tool. A great deal of work is done in this way, though this sphere has also been invaded by the draw press, whose output would seem incredible to those not familiar with metal work. Objects made thus are produced by dozens per minute, and all the movements of feeding and stamping and removal are often automatic. The ductility of metals and alloys is utilized in wire and tube drawing through dies on long benches. This work also involves frequent annealing, for otherwise the wires or tubes would rupture. Even hard steel is treated in this way to form tubes for the highest hydraulic and steam purposes.

**Platers' Work (see Boiler).**

This is distinguished from work in sheet metals by the fact that plates have considerable thickness, which sheets have not. Plates range in thickness from \( \frac{1}{2} \) in. to 2 in., but they do not range as thick as they do in sheet metals. In these thicknesses they are used chiefly for the largest marine boilers. Armour plates which are several inches in thickness do not come in this group, being a special article of manufacture. Sheets are of thicknesses of less than \( \frac{1}{2} \) in. This distinction of thickness is of importance in its bearing on workshop practice. A thin sheet requires a very different kind of treatment from a thick plate. Not only is more powerful machinery required for the latter, but in bending it allowance has to be made for the difference in radius of outer and inner layers, which increases with increase of thickness. Sharp, short bends which are readily made in thin sheets cannot be done in thick plates, as the entire thickness is stressed. Bending is therefore more difficult in plates of the outer layers. The methods of union also differ, riveting being adopted for thick plates, and soldering or brazing generally for thin. This difference in the methods of union is an important phase of sheet-metal work. It is divided into two great departments: the domestic utensil side, on which the brazier's craft is exercised; and the engineering side, which is concerned in some engine-work, locomotive and marine, and in the manufacture of the breweing utensils. The methods of the first are allied to those of the tinman, those of the second to the methods of the plater. Tinmiths' work resembles the lighter part of the work of the coppermith. There is no essential difference in dealing with tin (i.e. sheets of iron or steel coated with tin) and copper of the same thickness. Hence the craft of tinmen and braziers is carried on by the same individuals. There are, however, differences in method, and in detail, in the work done for the outer and inner layers. The geometry of sheet-metal work and of platers' and boiler-makers' work is identical up to a certain stage. The divergence appears when plates are substituted for sheets. A thin bent plate of practical dimensions may be bent on a geometrical pattern marked on it will develop the object required after it is bent. Nearly all patterns are the developments of the envelopes of geometrical solids of regular or irregular outline, few of plane faces; when they are made up of combinations of plane faces, or of faces curved in one plane only, there is no difference in dealing with thin sheets or thick plates. But when curving occurs in two or even three dimensions the metal is to be changed in shape if it is not done by hand-work in copper. In thick plates it is not attempted by hand, but pressing is done between dies, or segments of the sphere are prepared separately and joined together by brazing. In thin work done in thick plates the dimensions marked out must have reference to the final shape of the article. Generally the dimensions are taken as in the middle of the plate, but they may be on the inside or outside according to circumstances. But in any case the thickness must enter into the calculations, whereas in thin sheets no account is taken of thickness. The metal-work in wrought-iron sheet that are bent in one plane only are easily made. The shapes of all polygonal and all cylindrical and conical forms are obtained by simple development—i.e., by revolved drawings. The development of the plane and when cut, are bent or folded to give the required envelopes. Only common geometrical problems are involved in the case of sheets of sensitive thickness, and allowances are made for thickness. But when the form involves curvatures that must be taken into consideration, the directions the layers or fibres of metal are made to glide over one another, extension taking place in some layers but not in others, and this goes on without producing much reduction in the thickness. As a general rule it is restricted to metals which are not cast, for, with some slight exceptions, it is impossible to produce relative movements of the layers in cast iron, steel or cast brass. But hot rolled metals and alloys can be so treated, copper being the best for the purpose. The methods employed are "raising" by the hammer, and pressing in dies. But the severity of the treatment would tear the material asunder if rearrangement of the particles were not obtained by frequent annealing (p. 39).

If an object has to be beaten into concave form from a flat thin sheet, the outer portions must be hammered until they occupy the correct position, at the same time the extremities being extended, and this is enormous. Another illustration of the malleability of metal is afforded by metal spinning. A sheet of metal set revolving at a high speed on a mandrel bent or shaped to the form of the numerous mouldings, by a blunt hardened tool. A great deal of work is done in this way, though this sphere has also been invaded by the draw press, whose output would seem incredible to those not familiar with metal work. Objects made thus are produced by dozens per minute, and all the movements of feeding and stamping and removal are often automatic. The ductility of metals and alloys is utilized in wire and tube drawing through dies on long benches. This work also involves frequent annealing, for otherwise the wires or tubes would rupture. Even hard steel is treated in this way to form tubes for the highest hydraulic and steam purposes.

**Cast Work.**—The metals and alloys which are neither malleable nor ductile can only be worked into required shapes by melting and pouring in a mould. The earliest example of this is the Sumerian ingot, dated from the Neolithic period testify to the high antiquity of this class of work, and also to the great skill which the ancient founders had acquired. Statue-founding is a highly specialized department of metal-work, but may be divided into casting in the furnaces and casting in the mould. If ingots have been employed, the cire-perdue, or wax process (see above), and the present, or absent method. In the latter the artist provides a model in plaster from which the founder takes a mould within an enclosing frame, and in this the model is covered with a series of little separate sections (false cores or drawbacks) to permit of their removal from the mould without causing fracture of the sand. These are subsequently replaced piece by piece in the encircling frame, and a core made within it, leaving a space of \( \frac{1}{2} \) in. or thereabouts in which the metal is poured. The advantage of this process is that the artist's model is not destroyed in the cire-perdue, but is left and results of the work performed. A large statue occupies from one to three months in the moulding.

The extreme tenacity of objects which are hammered, drawn or rolled cannot for obvious reasons be attained by casting. Casting retains a certain amount of grain, and the metal never acquired a true smooth surface. The importance of sheet-metal work is that the metals have been employed, the cire-perdue, or wax process (see above), and the present, or all cast method. In the latter the artist provides a model in plaster from which the founder takes a mould within an enclosing frame, and in this the model is covered with a series of little separate sections (false cores or drawbacks) to permit of their removal from the mould without causing fracture of the sand. These are subsequently replaced piece by piece in the encircling frame, and a core made within it, leaving a space of \( \frac{1}{2} \) in. or thereabouts in which the metal is poured. The advantage of this process is that the artist's model is not destroyed in the cire-perdue, but is left and results of the work performed. A large statue occupies from one to three months in the moulding.

There are many metals and alloys which are malleable and ductile, and also readily fused and cast. This is the case with gold, silver, copper, tin, lead and others, and especially with low carbon steel, which is first cast as an ingot, then annealed and rolled into plates and bars for the thinnest sheets. The ancient wootz, and the products of the iron furnaces of Africa are first cast, then hammered out thin. Many of the patent bronzes are by slight variations in the proportions of the constituents made suitable for casting, for forging, rolling and drawing. In the methods of manufacture for the metal for the casting, forging, rolling and drawing. In the methods of manufacture for the metal for the casting, the fact that the alloys have been treated, of carbon and other elements in its composition than has cast iron, Steel intended for castings has slightly more carbon and other elements than the cast-steel ingot intended for rolling into plates. So also with the numerous brasses, bronzes, and other brasses, and other alloys of copper; each is made in several grades to render them suitable for different kinds of treatment. One of the most difficult problems with which the metal-worker

METAMERISM (Gr. meta, after, μετοχή, a partition) is generally

termed in natural science. In chemistry it denotes the existence of different substances

containing the same elements in the same proportions and having the same molecular

weight; it is a form of isomerism.

In zoology, metamersism is the repetition of parts in an organized

body, a phenomenon which is, as E. Haeckel, W. Bateson

and others have recognized, only a special case of a tendency
to repetition of structural units or parts which finds one expression

in bilateral symmetry. It occurs in almost every group of the animal kingdom, but is most conspicuous in segmented worms, arthropods and vertebrates. In certain worms (the

Cestodes and some Planarians) metameric segmenta-

tion is accompanied by the separation of the completed meromers

one by one from the older (anterior) extremity of the chain

(strobilation), but it by no means follows that metameric segmenta-
tion has a necessary origin in such separation and forma-
tion of the "meres." On the contrary, metamersism seems to arise from a property of organisms which is sometimes more

eumerogenesis and sometimes less (dysmerogenesis) fully

exhibited, and in some groups not exhibited at all. The

most complete and, at the same time, simplest instance of

metamerism is to be seen in the large Chaetopods, where

some hundreds of segments succeed one another—each practically

indistinguishable in structure from the segment in front or from that behind; muscles, right and left appendage or parado-

podium, colour-pattern of the skin, gut, blood-vessels, coelom,

nephridia, nerve-ganglion and nerves are precisely alike in

neighbouring segments. The segment which is least like the others is the first, for that carries the mouth and a lobe projecting

beyond it—the prothorium. If (as sometimes happens) any of the hind segments completes itself by developing a pro-

thorium, the chain becomes a true helm-shape which has developed a prothorium becomes the first or head-bearing

segment of a new individual. Compare such an instance of

metamerism with that presented by one of the higher Arnthropods—e.g. the crayfish. Here the somites are not so clearly marked in the tegumentary structures; neverthe-

less, by examining the indications given by the paired parapodia, we find that there are twenty-one somites present—a limited

finite number which is also the precise number found in all the higher Crustaceans.

We can state as a first law" metameric or somite formation

1 The word "law" is used in this summary merely as a convenient

heading for the statement of a more or less general proposition.
that it is either indefinite in regard to number of metanemes or somites produced, or is definite. Animals in the first case we call anomonemeric; those in the second case, nomonemeric. The nomonemeric condition is a higher development, a specialization, of the metamerism condition.

The SECOND LAW, or generalization, as to metamerism which must be noted is that the meres or somites (excepting the first with its paired appendages) all practically obviously may be considered another greatly by modification of the various constituent parts of the mere or somite. Metamerized animals are either homonomeric or heteronomeric. The reference of the variation in the form of the entire organism is in a general sense either "tail" or "head" and produces us to the necessity of a general term for these constituent or subordinate parts; they may be called "meres" (μέρος). The meres present in a metamer in a somite differ in different species, or in a different geographical organization of the group to which the animal belongs. As a matter of convenience we distinguish in the Arthropod as meromes, first, the tegumentary chitinous plate so as to suggest some as to the body and somites; second, the similar plates. In Chaetopterans we should take next to these the masses of circular and longitudinal muscular fibres of the body-wall and the dorsal-ventral muscles. The latter form the third sort of merome present in the Arthropods. The fourth form of merome is constituted by the parapodia or appendages; the fifth by the coelomic pouches and their ducts and external appendages, (whether thoracic, abdominal, or terminal); the sixth the blood-vessels of the somite; the seventh by the alimentary tract which traverses it; and the eighth by the neurones (nervous ganglion pair, commissures, connectives and nerve branches).

The NOMOTAGMIC LAW of metamerism is applicable in such a way as to produce definite regions of like modification of the somites and their appendages, differing in their modification from one to another so as to be convenient to have a special word for such regions of like meres, and we call each a tagma (ταγμα, a regiment). The word "tagmosis" is applicable to the formation of such regions. In the Chaetopterans tagmosis always occurs to a small extent so as to form the head, the segments and terga or sternites being largely claimed in one. But of equal importance is the independent "heteromosis" of these visceral meres without any corresponding heteromosis of the body wall. We may cite the meromes of the head and the special localization of renal, genital and gastric meromes with obliteration elsewhere, in a few somites in Arthropods.

The FIFTH LAW, relating also to the independence of the meromes as such, is that "the number of somites may increase by gradual elongation—what is called "budding"—of the anterior border of the hindmost somite. This, however, is not true of all the somites and is called the EIGHTH LAW of metamericism. A new somite is, therefore, to be, new metameres or somites are only produced at the anterior border of the telson, except in the Vertebrata."

The SIXTH LAW is the law of dislocation of meromes. This is a very important and striking phenomenon. A merome, such as a peduncle (in the Crustacea) or a tail (in the fishes), or a muscle (frequent), may (by either a gradual or sudden process) be taken always by which) quit the metamer to which it belongs, and in which it originated, and pass by actual physical transference to another metamer. Frequently the metamerization of several meromes from that to which the wandering merome belongs in origin. The movement is more usual from behind forward than vice versa. The reverse direction; but this, probably, has no profound significance and depends simply on the fact that as a rule, the head must be the chief region of development on account of its containing the sense organs and the mouth.

In the Vertebrata the independence of the meromes is more fully developed than in other metamerized animals. Not only do we get auto-heterosis of the meromes on a most extensive scale, but the number of somites or segments of the trunk varies. The exception lies in the development of the pelvic fins; the branchiomerostes lose all relation to the trunk, and only assume their true relations to the trunk musculature from the time which their nervous nature, and the heart and its vessels may move backwards from their original metameres in higher Vertebrates carrying nerve-loops with them.

The NINTH LAW of metamericism is one which has been pointed out to the writer by E. S. Goodrich. It may be called the law of "transposition of heterosis." Whilst actual physical transference of meromes to the trunk is more frequent, the as the passage of the pelvic fins from the front to the pectorals, and in the case of the backward movement of the opisthopterous appendages of spiders, yet the more frequent mode of inter-typic transposition is the position of a specialized organ. In series or scale of meromes takes place is not by migration of the actual material organ from somite to somite, but by translation of the quality or morphologic condition accompanied by correlative change in all the somites of the series. The phenomenon may be compared to the transposition of a piece of a larger to a higher or lower key. It is thus that the lateral fins of the fish are translated up the series, and the pelvic fins of the mammal (the anterior pair), a translation of a different scale. Thus our law has thus been extended; or in Crusta-

The XTH LAW of metamericism is the law of homoeosis and metamorphic. We will venture to call this the NINTH LAW of metamericism, as it is termed by W. Bateson. Homoeosis is the making of a soma into the likeness of one belonging to another metamere, and is the opposite of the process of "heterosis" in its nature. Our law here because the result of its operation is to simulate the occurrence of dislocation of meromes and has to be carefully distinguished from that process. A merome can, and does in individual cases of fasciparous multiplication or budding, assume the character of the corresponding merome of a distant somite. Thus the antenna of an insect has been found to be replaced by a perfectly well-formed walking leg, or a leg by a wing, and in the latter case we find all the features having the form of an antenna. Other cases are frequent in Crusta-

The XIth LAW of metamericism is the law of the phenomenon which we call "intercalation" of meromes. Thus the question of intercalation of vertebrae in the Vertebrata has received some attention. It has been thought that a vertebra even taken with its muscular and vascular and neural accessories is only a partial metamere—a merome—and that, so far as complete meromes are concerned, the Vertebrata do conform to the same law as the Arthropods. Inter-
course of the historical development of those various groups of metamorphosed animals, which have undoubtedly sprung from ancestors with more numerous somites than they themselves possess, it is a question how much it is advisable to regard the thirteenth, the twentieth, and the thirteenth laws of metamorphosis.

The TENTH law is that individual somites tend to atrophy and finally fuse to form solid structures at the anterior and posterior ends of the series constituting an animal body. This is very generally exhibited in the head of Arthropoda, where, however, the operation of the law is largely modified by fusion (see below). In the abdomen of most insects and crustacea, the segmentation of segments does not, as a rule, affect the telson itself so much as the somites in front of it and its power of producing new somites. Sometimes, however, the telson is very minute and nonchitinous (Haliotis).

The ELEVENTH law may be stated thus: any somite in the series which is the anterior or posterior somite of a tagma may become thickened and aborted after the manner of the older somites and may ultimately be absorbed by the formation of some of its mesomeres; and finally, such a somite may disappear and leave no obvious trace in the adult structure of its presence in ancestral forms. This is called the exfoliation of a somite. Frequently, however, such "exfoliated" somites are obvious in the embryo or leave some remorne (e.g. neuromeres, muscle or chitin-plate) which can be detected by minute observation. The evidence of their former existence and reappearance of the somite of the maxillipeds (third post-epipodial appendage) of Apus cancuiformis is a good example of a somite on its way to exfoliation. The third pre-oral and the praemaxillary somites of Hexapoda in some cases are the only ones that the vestigial appendages are furnished by the microscopic study of early embryos. The praegnatorial somite of the Achelia is an example of a somite which is preserved in some members of the group and partially or entirely calcareous. In other cases, sometimes with fusion of its remnants to neighbouring somites.

The TWELFTH law of metamorphosis might very well be placed in logarithmic order at the head of this series. It is that just as the metameric condition is produced by a change in the bodies of the descendants of uniseggmental ancestors, so highly metamized forms—i.e. strongly segmented forms with specialized regions of different nature—may be produced by reducing the metameric structure and become apparently and practically uniseggmental animals. The change here contemplated is not the atrophy of terminal segments one by one so as to reduce the size of the body by gradual incision. On the contrary, there is no loss of size or of high organization is necessary. But one by one, and gradually, the metameric grouping of the bodily structures disappears. The cuticle ceases to be thickened in rings—the muscles of the body-wall overrun their somite boundaries. Internal septa disappear. The nerve-ganglia concentrate or else become diffused equally along the cords; one pair of renal coelomoducts and one pair of genital coelomoducts grow to large size and remain—the rest disappear. The appendages atrophy or become limited to one or two pairs which are widely dislocated from their ancestral position. The animal ceases to present any indication of metameric repetition or organization. During this process are frequently to be recognized. We certainly can observe such a change in the posterior region of some Arthropoda, such as the larvae of certain spiders. We can thus demonstrate that the somites are descended from Chaetopoda, such a change has taken place in them, amounting to little short of complete lipomeralism, though not actually complete.

Recent suggestions as to the origin of the Mollusca involve the supposition that such an effacement of once well-marked metamorphosis has occurred in them, leaving its traces only in a few structures such as the multiple gill-plumes and shield-shells of the Chitons and the duplicated renal sacs of Nautilus.

A further matter of importance in this connexion is that when the old metameres have been effaced a new secondary segmentation may again appear, as in the jointed worm-like body of the degenerate Acarid, Demodex follicularum.

Such secondary annulation of the soft body calls to mind the secondary annulation of the metameres of leeches and some earthworms. It may be a case of an allusion to a subject; but it is worth while noting that the secondary annuli marking the somites of leeches and Lumbricidae in definite number and character are perhaps comparable to the redundant pairs of appendages that the somites are in some cases very seldom, or almost never, many cases, the existence and development of which may be seen and their structure and movements can be described as independent of the external environment.

The last law of metamorphosis which we shall attempt to formulate here, as the THIRTEENTH, relates to the fusion or blending of neighbouring somites. Fusion of adjacent somites has often been erroneously described as the result of the action of the blastula of Arthropoda. The facts are that very varying degrees of fusion which need to be carefully distinguished. The following generalization may be formulated. "The homologous somites of two or more adjacent somites tend to fuse with one another by a blending of their substance. Very generally, but not invariably, the fused somites are found as distinct separated structures in the embryo of the animal, in which they unite at a later stage of growth." The fusion of neighbouring somites is often preceded by more or less extensive atrophy of the somites concerned, and by arrest of development in the individual ontogeny. This is frequently, but not always, the case in the formation of partially atrophied somites may simulate the appearance of anecdot omogenesis or formation of new somites, and, vice versa, incipient meromeres may be misinterpreted as a new formation of once separate and fully-formed somites. A very common form of this is shown in the head of Arthropoda. The head or prosoma of Arthropoda is a tagma consisting of one, two, or three prothorax or somites in front of the mouth and of one, two, three, up to five or six opisthosomites. The cephalic tagma or prosoma may thus be more or less sharply divided into two subtagmata, the pre-oral and the post-oral.

METAMORPHISM (Gr. μετάμορφος, change of, μορφή, shape), in petrology, the altera tion of rocks in their structural or mineral characters by which they are transformed into new types. In the history of rock masses changes of many kinds are inevitable. Loose sands, clays and heaps of shells are gradually converted into sandstones, shales and limestones by the action of percolating water and the pressure of over-lying accumulations. All rocks exposed at the earth's surface or traversed by waters circulating through the earth's crust, undergo changes in their component minerals due to weathering and the chemical action of the atmosphere and of rain. These processes are known as "metamorphosis"—change and decomposition, though not unlike those of metamorphism, are not regarded as essentially the same. They are considered, so to speak, normal episodes in the history of rocks to which all are subject. When rocks, however, are exposed to the heat of intrusive masses (granite, &c.) or have been compressed, folded, crushed, and more or less completely recrystallized, they assume new characters so different from their original ones that they are ascribed to a quite distinct class, namely, the metamorphic rocks.

The transformation is always gradual, so that in suitable districts every stage can be followed from an unaltered or nearly unaltered sedimentary or igneous rock to a perfectly metamorphic one. The transition may be slow or rapid, and the abundance of intermediate forms renders it impossible to lay down any hard and fast lines of distinction. A black shale with fossils may in two or three feet pass into a splintery hornfels; a sandstone or grit becomes a sheared grit, a granulitic gneiss, and a completely recrystallized gneiss sometimes within a few hundred yards; in a thoroughly metamorphosed hornblende-chert, a "bottle-shaped" stone, a "cheese," or "carrot," which can easily be recognized as little modified dolerites or diabases.

Still, the metamorphic rocks as a class have many well-defined characteristics, and in perfectly typical development cover enormous areas of the earth's surface and must be, in the aggregate, of vast thickness. A great number of them are recognizable of igneous origin; others are equally certainly sedimentary. Hence some writers have suggested that they are not entitled to rank as a separate class, but only as states or conditions of other rocks. It is generally agreed, however, that when the primitive structures and the original minerals of sedimentary or igneous rocks are so transformed as to be no longer easily recognizable the rock should be included in the metamorphic class.

Only rarely, however, does metamorphism produce much difference in the chemical composition of the rocks affected. Sandstones become quartzites and quartz schists, limestones are converted into marbles, granite passes into gneiss, and so on, without their bulk composition being greatly modified. From all that we know it seems established that however great the heat and pressure to which metamorphic rocks have been exposed, the changes that have been undergone by them are produced by liquid state. Hence there has been no opportunity for inter-mixture by solution or diffusion; the changes, including the growth of crystals of new-formed minerals, have gone on in the solid rocks. The chemical molecules already present have aggregated into new combinations and have built up new minerals without travelling for more than infinitesimal distances from the places they occupied in the original rock. Exceptions to this occur, but they are so few that they do not
METAMORPHISM

invalidate the general rule. Thin bands of limestone, for example, may be followed for miles in belts of mica-schist or gneiss, never losing their identity by blending with the rocks on either side of them. By traversing one of these belts, it is possible to unravel the highly complicated stratigraphy of metamorphic regions where the rocks have been greatly folded and displaced. Another important consequence of the persistence of the chemical individuality of metamorphosed rocks is that very often an analysis indicates in the clearest possible fashion what was the original nature of the rock mass.

Sandstones, limestones, ironstones, shales, granites, dolerites and serpentines may be totally changed in structure and very completely also in mineral composition, but their chemical characters are practically unaltered. Hence, the change from limestone to marble, or from limestone to marble in contact with a granite, may have much of the same composition, e.g. a felspathic sandstone may closely approach a granite, or an impure dolomite may simulate a basic igneous rock. Individual specimens, consequently, cannot always be relegated with perfect certainty to sediments or igneous rocks; but in dealing with a complex containing a variety of types the geologist is rarely long in doubt as to their original nature.

Two distinct kinds of metamorphism are recognized, namely contact or local, involving metamorphism, and folding or regional metamorphism. The former is associated with intrusive masses of molten igneous rock which were injected at a very high temperature and produced extensive changes in the surrounding rocks.

The second occurs in districts where earth folding and the movements attendant on the formation of mountain ranges have flexured and crushed the strata, probably at the same time considerably raising their temperature. Although these processes are very different in their origin, and in the great majority of cases produce quite different effects on the rocks, in many cases the results are comparatively similar. A sandstone may be converted into quartzite and a limestone into marble by either kind of metamorphism.

It is best, however, to describe them as phenomena essentially different from one another.

Contact Metamorphism (thermo-metamorphism).—Any kind of rock—igneous or sedimentary—which has come in contact with an igneous molten magma is likely to show alteration of this type. The extent and nature of the changes depend principally on the following factors: (1) the nature of the rock concerned, and (2) the magnitude of the mass of magma. It is to be expected that a great intrusion of granite will produce more extensive effects of this kind than a narrow mass a few inches or a few feet broad. At the edges of such dikes only a slight indentation may be noticeable in the country rock, or there may be recrystallization with formation of new minerals; but in the centre of the intrusion, especially where the granite is exposed, the changes will be so great that it is virtually a new rock. Shales, slates and marble, quartzites and other similar rocks, rendered more compact or occasionally are partly fused, limestones may be converted into marble containing garnet, wollastonite, augite or other calc-silicates. A great granite boss, which may be ten or twenty miles broad, is often surrounded by a wide aureole of contact alteration. This may be a few hundred yards broad or a couple of miles; in rare cases the breadth of the aureole is only a few yards. These variations may have structural causes, thus when the aureole is narrow the junction of granite with country rock may be vertical; when the aureole is broad the granite may be a few degrees inclined. The outer edge of the aureole is often deeply baked and the minerals have been converted into new compositions. When a broad aureole accompanies a vertical junction we may suppose that molten rock has flowed upwards along this boundary line for a prolonged period, and has gradually raised the rocks to a very high temperature, even at some distance away from the contact. Where the alteration is slight and local there is usually something in the composition of the rocks or in their crystalline state to account for this.

No less important is the nature of the rocks involved. Where a granite intrudes into a succession of various types of sedimentary and igneous rocks the differences in their behaviour are often very pronounced. It is usually the primary rocks which are affected, and the secondary species such as quartz, feldspar and garnet are formed. These changes are of course greatest in the vicinity of the contact and may extend for a distance of a few miles into the country rock. The secondary products, including those which fill veins and amygdule cavities, are often entirely recrystallized in new combinations. Instances of this will be given later.

The intensity of the alteration depends very greatly on the presence or absence of the surrounding rock. The surrounding rock, as for example, a contact aureole arising from a granite boss, for example, consists of rocks in all stages of alteration, the most affected being nearest the granite, while as we travel outwards we pass stages of successively increasing meta- morphic change. Around the granites of Cornwall, the Lake District and Ireland there are tracts of altered slate which show these stages very well. The first sign of metamorphism is a slight increase in bulk and cleavage, followed by the production of a hornfels and more brittleness. This is due to the formation of mica in small crystalline plates mostly parallel to the cleavage of the rock. Nearer the granite a faint spotting is visible on broken surfaces of the slates, and as we pass outwards more and more structures are developed and the slate becomes more and more mica and hornfels. Where the altered slate joins the unaltered granite it is termed an aureole. These spotted slates, in Cornwall for instance, often occupy a zone a mile in breadth. They are less fissile than the unaltered slate but they may cleave in much the same manner and the two regions are very difficult to distinguish in the field. The spots are usually darker than the body of the slate, though sometimes paler. Angular, branched, lenticular and rhomboidal spots sometimes occur. Under the microscope these rocks consist mainly of brown mica, quartz and organic matter, iron oxides, &c.; the spots may be due to aggregation of biotite or of quartz, but often differ little in composition from the surrounding rock. Their dark colour is due to abundance of iron oxides or biotite. This is in contrast with chlorite, hornblende, etc., and the development of crystals takes place in the slates; the commonest member are andalusite, chloritoid, with (cross-shaped dark enclosures), cordierite, biotite, chlorite, andalusite (gray), pargasite, with some other varieties. These latter minerals, as already enumerated crystallize in larger individuals (biotite, quartz, iron oxides, &c.), so that the rock becomes rather more coarse-grained. At this stage the fissility and cleavage structures of the slate tend to disappear, and the rock is described as a hornfels, and is made up of small flakes of mica, hornblende, &c., with a good cleavage. The aureoles in the granite may be only a hundred yards broad, or may be several miles.

The nature of the new minerals produced depends principally on the composition of the rocks which are involved. The quantity of pure slates only quartz is formed, and pure slates merely recrystallize as micas. Argillaceous rocks are characterized by abundance of alumina; hence, when thermally altered, they may contain only chlorite, talc, serpentine, diopside, etc. The mixed limestones, granite, mica, serpentine, and talc, are characterized by the formation of micas, chlorite, talc, and chlorite, andalusite and chlorite. Most rock masses, however, are far from pure and hence the variety of minerals which may arise in them from contact alteration is very great. Argillaceous limestones, for example, very frequently contain garnet, quartz, wollastonite, diopside, tremolite, spodumene, epidote and feldspar; that is to say, minerals in which lime is present along with silica, alumina, magnesia and iron oxides. In the mixed rocks, those which contain quartz, feldspar, diopside, epidote; argillaceous slates are characterized either by biotite, sillimanite and spilitic.

In each case the materials already present in the rock have been united to form new minerals. Contact metamorphism is produced by the crystallization of a solution driven out of the country rock by the large volume of heat produced by the fusion of the granite. Crystallization has been stimulated by the rise of temperature, aided, no doubt, by moisture. Water vapour, even at comparatively low temperatures when the water is driven off as steam, is capable of converting the rock into mica, making it more resistant to solution. The flow of water through the rock facilitates crystallization. Often the rocks acquire ultimately a pseudomorphologic or phyllosilicic composition, as they contain large or conspicuous crystals scattered through a finer grained ground-mass; not only these phyllosilicic ingredients but the body of the rock shows increased crystallization, for contact alteration as a rule makes rocks more coarse-grained than before.

In rare instances fusion may take place, but this must be exceptional, as the finest original structures are often very perfectly preserved by rocks which have been in great measure recrystallized. Finely laminated argillaceous sandstones, for example, may pass into a fine-grained igneous composition, and the country rocks may be partially or entirely fused. Crystallization, in other words, produces a granite, a gneiss, a migmatite, a mixed rock which corresponds exactly with the original lamination. For this reason the newly developed minerals are not frequently of good crystalline form. When weathered out of the rock they have mostly a granular structure. They are transformed into hornfels and may be regarded as the result of the alteration of rocks already within the granite. This is also true of the granite itself, the hornfels, tourmaline and a few others which often produce good crystals even in these adverse circumstances.

Though we have as yet been dealing with a general way that the rocks which are thermally altered experience no change in their chemical composition. The new minerals which are substituted for the original ones are such as are stable at high temperatures. Many of the silicates which are found in the granite form part of the basic series; for example, chlorite, jadeite, feldspar, serpentine, biotite, hornblende, etc., can be directly formed from granite. This is also true of the granite itself, the hornfels, tourmaline and a few others which often produce good crystals even in these adverse circumstances.

No less important is the nature of the rocks involved. Where a granite intrudes into a succession of various types of sedimentary and igneous rocks the differences in their behaviour are often very pronounced. It is usually the primary rocks which are affected, and the secondary species such as quartz, feldspar and garnet are formed. These changes are of course greatest in the vicinity of the contact and may extend for a distance of a few miles into the country rock. The secondary products, including those which fill veins and amygdule cavities, are often entirely recrystallized in new combinations. Instances of this will be given later.
vene deposited by ascending hot waters. Hence contact aureoles are common sites for mineral deposits of economic value.

In the contact zone, where there has been regional folding and foliation plains wedged apart by the intrusive force of the granite, and are permeated byigneous material invading them along these fissures. In this way a mélangé is produced of sedimentary rock with igneous rocks and vice versa. A similar mingling of the two rocks takes place, though usually each preserves its identity however intimately mixed. In microscopic sections, veining and foliation plains at a tenth or a thousandth width may be traced, sharply distinct from the slate or schist they enclose. Cases, however, are described in which the rocks of the aureole have been felspathitized or filled with new felspar derived from the granite; this process is called albization. Shales, slates, and marbles, in contact with diabase, into pale-colored, flinty-looking rocks known as adinoles. These are exceptionally rich in albite and contain as much as 5% of soda, an amount which is not met with in unaltered slates. It is thought that porphyroblasts are growing in the igneous rock to the sedimentary, perhaps through the medium of the vapours exhaled. The breadth of the adinole belt is as a rule only a few inches or a foot or two.

The vapours given off by intrusive igneous masses may contain substances which combine with the ingredients of the surrounding rocks and thus modify their composition. Boron, fluorine and phosphorus are the principal elements which are transferred in this way, and minerals such as tourmaline, topaz and mica are the characteristic products in quartzite or argillaceous rocks; while apatite, grossularite, andradite and chlorite are commonest in limestones. This is a form of pneumatolytic action (see Pneumatolysis).

Extreme cases of the mutual interaction of the intrusive rock with the country rocks are well known. Molten igneous rock and the fragments of the parent rock, mixed in the molten magma (known as xenoliths). These are often rounded and eroded, as if softened or partly fused and dissolved. Similar changes are found in the rocks of the aureole for a few feet or yards where in actual contact with the granitoid. This is called hornfelsing, and hornfelses often wear much more slowly than the igneous rock, and stands out as a prominent, sharp-edged ridge running the whole length of the formation.

Where sediments are dissolved in igneous rock we may expect to find modifications in the chemical composition and in the minerals produced on crystallization of the magma. Some grains, for example, may be dissolved; or 

**METAMORPHISM**

Metamorphic rocks of this kind often cover a large part of a continent (e.g. the centre of Africa or Scandinavia and Finland). Whether the causes be which produced it, they must have been of wide extension and of very long periods of time—possibly millions of years, and processes or with definite stages of the earth's development. Where such rocks occur there is generally much evidence of earth movement by crushing and folding. They are very characteristic of the central regions of great masses of granite, especially when these have been denuded and their deeper cores exposed. Most geologists believe that this connexion is causal, holding that the crystallization of the granites, due to the shrinkage of a nearly rigid shell upon a cooling and contracting interior, has bent and folded the rocks, and at the same time has crushed and largely recrystallized them. According to this view regional metamorphism may be regarded as the immediate result of this hypothesis, forming a mass of evidence so strong as to be almost overruled by the general. This may prove the name "dynamo-metamorphism" is frequently applied to it.

A great number of observations collected in all regions of the globe, and that can be adduced in favour of this theory. One of the most important is the breaking up of their original elastic or igneous textures, fine skeletal struc- tural features which prove that there has been great folding in these rocks are accompanied by microscopic and lithological characteristics which demonstrate that extensive crushing and flattening. Through progressive stages a slate with fossils may be traced into a phyllite, which becomes a mica-schist, or, in places, a micaceous gneiss. Various types of normal and torn apart, but they disappear as crystallization advances. The differentiation of the composition of the magma to its formation. Where the degree of metamorphism is not very high, and the folding and dislocation not too complex, the sandstones, shales and limestones may be mapped out, and igneous bosses, dikes and sills, with their contact aureoles, veins, pegmatites and segregations, convincently delineated on the maps. This shows that a whole complex or terrane, consisting of diverse petrographic types of normal sediments and igneous rocks, may be converted by metamorphism into a great series of gneisses and schists.

Although recrystallization has been complete, the original rock may be recognizable by the identity in their new state.

The metamorphosis in such a mass of nearly uniform intensity over a large area; the sediments, for example, may have all their characteristic and structural essences effaced, and in the igneous rocks the coarse types of the primary mineral textures may have completely disappeared. This, however, is not always the case, especially when the metamorphism is not of very intense degree. Parts of the rock may retain original structures, while others are typical crystalline fields, consolidated as a normal gneissic texture. Parts or phacoids of massive rock are often found embedded in schists, and it is clear upon inspection that the phacoids represent the original state of the rock, while the schist is the effect of meta- morphism. At other times a rock mass, such as an intrusive sill, is schistose at its edges and surrounded by schistose sediments, while near its centre it is almost entirely massive. The hard igneous rocks are more resistant to weathering than the softer and plastic sediments; in folding, the latter have yielded to the former. As internal movement has produced foliation. The crystalline rock of the intrusive sheet has been strong enough to withstand the pressure and has folded and broken down into sheets, showing deformation. The development of differential movement is shown by the presence of a belt of rock which often has a most pronounced schistosity. Some intrusive dikes show foliation especially marked along their edges; or they may be traversed by another movement, folding, and the foliation may be directly across them, and characterized by the development of very marked schistosity. Exceedingly sudden transitions between these states of rock are found, in which a rock of one kind is changed into another in a layer of sheared dikes. A normal dolerite, with ophiolithic structure, and abundant augite, has been shown to pass in a few feet or inches into an epidiorite, where hornblende has replaced the primary augite. This lastly into another typical hornblende-diorite, entirely recrystallized with development of epidote, green hornblende, sphene and other minerals of metamorphic facies from the chemical constituents of the original. These phenomena are classified as regional metamorphism, and it is believed that the rocks and give rise to the new mineral assemblage that have developed rock before the processes which caused the metamorphism began to act; that these processes resulted in internal movement in the rock.
METAMORPHISM

mass along certain narrow belts; and that recrystallization was set up along with the development of schistose structure. The operating cause cannot have been anything but pressure, especially as the foliated rocks occur in the form of broad belts; in the Highlands of Scotland, in the neighborhood of the dikes, and in other places; other belts of the foliated types are at the margins of the dikes, and the transition from massive igneous rock to metamorphic schist may take place within the space of one inch. The belts of schists and the surrounding rocks are called aureoles. By J. J. H. Teall from Scourie in the north-west of Scotland.

Where rocks of any kind are traversed by powerful diastrophisms or thrusts they often present a schistose structure in the direction of the movement. In the Highlands of Scotland great thrusts occur, along which the rocks are displaced for distances which may be as much as ten miles; and immediately the schistose structure is developed parallel to the direction of the movement. The minute structure of these rocks is generally of the mylonitic, granulitic or finely crushed type. In the same way the serpentine of the Lizard in Cornwall passes into fine talcose and tremolitic schists along narrow zones of displacement. Many other examples of this might be cited from regions where folding and crushing have taken place on a large scale. As a rule, almost without exception, the foliation thus produced is parallel to the direction of movement in the rock masses.

In the mineral transformations which accompany metamorphism the operation of pressure is no less clearly indicated. There are, for example, three minerals which consist of silicate of alumina, viz., andalusite, sillimanite and kyanite; these are the last of the three to be formed, and the highest temperature required for their formation in the smelting process would produce all kinds of rocks, sedimentary, igneous or metamorphic, which have been involved in the movements. The minute structure of these rocks is generally of the mylonitic, granulitic or finely crushed type. The principle that substances tend to assume that mineral form which has the least molecular volume is of wide application among metamorphic rocks. It has been caused that the larger crystals of hornblende are replaced by garnet (a change which takes place not infrequently when basic igneous rocks are metamorphosed) the molecular volume of the mineral aggregate diminishes from 143 to 121 or about 17%. On the other hand, the more complex the structure of a mineral, generally the greater its volume. When the fusion points and under great pressures have smaller molecular volumes. Locwinson Lessing pointed out that some minerals have a greater molecular volume than the oxides which enter into their composition; in other minerals the reverse holds good. The former group are, on the whole, characteristic of igneous rocks and products of contact alteration, both of which classes have been formed at high temperatures and pressure (andalusite, sillimanite, kyanite, andalusite). The minerals of the second group are often of common occurrence in metamorphic schists and gneisses (e.g. staurolite, kyanite, andalusite, hornblende, garnet, epidote, chlorite, chlorite). Some exceptions to this rule, there can be no doubt that it expresses a generalization which is of great value in the study of mineral paragenesis.

The stated changes are usually not of so simple a kind as those above enumerated. Mutual interaction takes place between adjacent components of the rocks. Titanium rich oxide minerals, for example, obtain silica and lime from such minerals as augite or lime felspar and plagioclase rocks. Felspar often breaks up into epidote, quartz and albite; the epidote obtains its iron from adjacent crystals of augite or hornblende. Equations can be written to show the transformation of one rock to another; for example (labradorite, augite, ilmenite) may be converted into amphibolite (acid plagioclase, hornblende, garnet, spinel and quartz). In this way, the molecular volumes for 671 and 610 BMPD are greater, but the density and refractive index of the metamorphic rocks is higher. One of the striking illustrations of this principle have been added. Caution, however, is required in applying it to concrete cases; if it was always strictly correct the metamorphic rocks should have a higher specific gravity than their representatives among sediments or igneous rocks. Very frequently this is not the case, and there must be some counteracting process at work. We find this antagonism of density and composition in the mechanism of the formation of metamorphic rocks to contain water of combination, e.g. epidote, muscovite, chlorite, hornblende, talc. This indicates that they were formed at temperatures above 300° C.

We arrive then by many independent lines of reasoning (stratigraphical, microscopical, chemical and mineralogical evidence being abundantly available) at the conclusion that pressure acting on sedimentary rocks at high temperatures has been able to change them into metamorphic rocks. This is the theory of dynamo-metamorphism, which has won acceptance from the majority of geologists who have made the petrology of metamorphic rocks their special study. It has still, however, many acute critics, and in recent years dissent has on the whole gained strength.

The chief objections is that by these processes it is possible to destroy original structures and to break down the minerals of which a rock consists, but not to induce crystallization and build up rock structure (which is what the theory assumes to have happened). In regions where the rocks though intensely folded are not highly metamorphic; in other places immense dislocations can be proved to exist, yet the rocks are only slightly altered or are converted into intensely metamorphosed rocks by the interposing water. Conversely, it is argued, there are many districts where metamorphism is very intense, yet evidence of folding and pressure is only slight. It seems, therefore, that another factor in all probability that factor is the action of water in rocks at a comparatively high temperature. All rocks contain interstitial water, and many also consist of minerals in which water of combination has been produced; which water of combination must be regarded as taking place in presence of water. It is almost equally certain that metamorphism must be accompanied by a rise of temperature in nearly every case—in fact it is difficult to imagine such a process going on without considerable heat. Now heated water (or water vapour) is a most potent mineralizer. Crystals of quartz, for example, have been produced containing a large water, heated in a furnace to a temperature of about 300° C.

The heat required for the more intense stages of metamorphism may be derived from more than one source. Most regions of igneous and metamorphic rocks contain belts of rocks which are of the same age and are in the same stage of metamorphism, which indicates that the heat which supplied the energy for these processes was derived from the magma by the fusion of the rocks in its path. In some cases the heat of the magma is sufficient to produce the entire process of recrystallization and crystallization. In others, the magma may have been insufficient, and the heat necessary was supplied by the friction of the rocks against each other. There are other cases in which the heat was derived from the friction of the rocks against the sides of the magma chamber, or from the friction of the rocks against the country rocks. In all these cases the heat was derived from the fusion of the rocks in the path of the magma.

Heat may also be produced by the crushing of the rock and the alteration of its structure. In many cases we find hard minerals possessing little cleavage (such as quartz) reduced to an exceedingly fine state of division, and it is clear that the stresses which have acted on regions of metamorphic rocks are often so powerful that all the minerals may have been completely shattered. The interstitial movement of the particles must also have generated heat. There are no experimental data to enable us to say what rise of temperature may have been produced in this way, but we cannot doubt that it was considerable. If the crushing was slow the heat generated may have been conducted away to the surface almost as fast as it was produced. If the heat was produced rapidly, as it probably was, the heat produced would explain why in some rocks there has been much grinding down but little crystallization. The heat also may be absorbed in promoting chemical action; for example, it is probable that the water which was used up in this way. With rising temperature the rocks would become more plastic and fold more readily. Then if the crushing and folding ceased, a long period would follow in which the temperature was maintained at a high level, and larger grains of the already recrystallized minerals would have been produced by weathering alone, might be expected to prevail. In the deepest zones the temperature and pressure are high from the first, and it is probable that the metamorphism has been produced by weathering alone. If staurolite, garnet, feldspar, sillimanite, kyanite and staurolite might be produced under these conditions. The earth's crust might in this way be divided into bathymetric zones, each of which was characterized by a type of metamorphism. The study of metamorphism has, in the first place, provided the greatest importance to this conception; they establish two or three types of metamorphism, each of which belongs, in their opinion, to a definite horizon. This is to some extent a restatement of the old idea, now discarded, that the geologic rocks were sediments of a peculiar kind formed only in the heated waters of the primordial globe; the first deposits were laid down under great heat and pressure and
are typical gneisses which may resemble igneous rocks; the schists of later origin exhibit a progressive transition to normal sediments. Without admitting that it is possible to classify metamorphic rocks according to the extent to which they have been so metamorphosed, we may admit that there is much reason to believe that the more intense stages of alteration characterize as a rule the rock masses which were oldest or most deeply situated during the epoch of formation.

While rocks near the surface which are under comparatively slight pressures yield to stress by fracturing, it is conceivable that at greater depths the minerals would become plastic and suffer deformation. "Flower zone" as this zone is called by van Hise estimates a depth of not more than 12 kilometres, depending on many factors such as the strength of the rocks and nature of the agent. The rate of movement may be comparatively rapid. Between it and the zone of fracture, which lies above, a gradual transition must take place. Doelter, on the other hand, believes that the depth at which plastic flow begins is at least 35 kilometres. The rocks which have been so profusely buried can now be exposed at any part of the earth's surface.

In the attempt to explain the existence of large masses of metamorphic rocks which are perfectly foliated, but at the same time coarsely crystalline, and show no grading down of their components, as might be expected on the hypothesis of pure dynamo-metamorphism, F. and U. unchangeable; Experiments under pressure of nearly all directions they tend to be dissolved on those sides which face the pressure, while the sides which are not compressed tend to grow by addition. But it is not necessary to have perfect cleavage; they may be produced, all having a parallel orientation, and the rock will be schistose, with foliation corresponding in direction to the extension of the mineral plates, and perpendicular to the stresses which caused them. "Minerals of one side and deposit on the other side are the interstitial moisture and vapours present in the rock. By this means schists and gneisses will be produced, which are perfectly foliated yet have their minerals homogeneously distributed. The question of micas in the field data are not present wanting to show how far this principle is operative and what and are its limits, but as a supplementary contribution to the theory of dynamo-metamorphism it must be of great importance. It may be described as the development of "schistosity by crystalization.""

More interesting still are E. Weischel's theories of pressure-crystallization and pleo-crystallization (pressure-contact action). He adduces evidence to show that many gneisses are igneous rocks which were foliated from the first, and a large body of evidence in many European countries confirm his statement. In his opinion phylloclasts which are under conditions of great pressure necessarily assume a banded structure, and contain minerals which are not identical with those of igneous rocks but with the components of the altered rock. Phylloclasts of this sort have undergone an alteration but not of the ordinary type as the recrystallized products also have a banding or foliation owing to the pressure action on them during metamorphism. Bonney urged the hypothesis that many gneisses were once igneous rocks which exhibit a flow banding and an imperfect idiomorphism of their minerals owing to their having been injected in a half-solid state; the component crystals by mutual attrition assume rounded or lenticular forms. Undoubtedly there is much truth in these hypotheses, yet in both cases they seem to necessitate the presence of extraordinary earth-pressures such as accompany mountain building. We know that heat greatly increases the plasticity of rocks and "metamelange." The igneous rock veins the sediment in every direction; the veins are often exceedingly thin and nearly parallel or branch again and again. In this way a banding or foliation is set up, and the mixed rock on the appearance of a gneiss. In the sediment, intensely heated, new minerals are set up. The igneous rock digests or absorbs the materials which it penetrates; and it is often impossible to say what is original and what is secondary. May it not be the case that the way break up and partly assimilate older basic rocks. Very good examples of this process are known, and they may be much more common than is at present suspected. Conditions which favor this process are those high pressures and the high temperatures of the earth's crust; the igneous rocks may also be much above their consolidation points. It is quite reasonable to believe that at deep level absorption of sediment by igneous rocks goes on extensively, while in higher zones there is little or none of this action.

(J. S. F.)
METAMORPHOSIS

In the frog (fig. 1) the structural changes which obtain full fruition at the metamorphosis take place gradually during the previous tadpole life. They relate mainly to the alterations of the respiratory organs and vascular system which are required for the purely terrestrial life of the frog, and to the appearance of the paired limbs. The changes in the respiratory and vascular organs are led up to in the tadpole, which during the greater part of its aquatic life is a truly amphibious animal, breathing by lungs as well as by gills; but a sudden change occurs in these organs at the metamorphosis. The limbs which were slowly formed during tadpole life—the posterior pair visibly, the anterior under cover of the operculum (fig. 1, B)—are of no use to the tadpole and must constitute a pure burden to it. The principal events of the metamorphosis are the sudden appearance of the anterior limbs, and the complete closure of the gill aperture (fig. 1, C). The appearance of the anterior limbs and the acquisition of functional importance by both pairs enable the frog to leave the water and pass on to the land to lead its terrestrial life. The other larval organs, such as the gills and the tail, gradually shrink in size and ultimately vanish. In the case of the gills this shrinkage had begun before the metamorphosis, but the tail shows no sign of diminution until the frog is ready to pass on to the land.

The distinguishing feature of this type of metamorphosis is that the animal is burdened for a certain period, both before and after, with organs which are useless to it. In the next type, which is exemplified by the metamorphous Insecta, this occurs to a much smaller extent, although the changes of habitat and the corresponding changes of structure are more remarkable. In insecta the change is usually from a terrestrial or aquatic habitat to an aerial one. The larva of a butterfly is a worm-like organism which creeps on and voraciously devours the foliage of certain plants (fig. 2, C). During its life it undergoes much growth, but no important change in structure. When it leaves the egg it is adapted to live and feed on a particular species of plant, on or near which the eggs are deposited by the parent butterfly. It has powerful biting jaws by which it procures its vegetable food. The adult, on the other hand, is a winged creature which also lives on plants but in quite a different way to the larva (fig. 2, A). It flies from plant to plant and obtains its food by sucking the juices of flowers and other parts. The powerful mandibles of the larva have disappeared and in their place we find a suctorial proboscis formed by the first maxillary segment (fig. 2, A (4)).

Between the larva and the adult insect there is interposed a resting stage, the so-called pupa (fig. 2, B), during which no food is taken, but very important changes of structure occur. These changes consist of two processes: (1) histolysis, by which most of the larval organs are destroyed by the action of phagocytes; and (2) histogenesis, by which the corresponding organs of the imago are developed from the imaginal disks. The imaginal disks appear to arise in the embryo in which they develop, some of them from the epiblast and some from the hypoblast. They persist practically unchanged through larval life and become active as centres of growth in the pupa. The pupal stage in such a metamorphosis may be compared to a second embryonic stage in which the organs of the adult assume their final shape. In this kind of metamorphosis the larval organs are entirely got rid of in the pupal stage, during which the insect is as a rule incapable of locomotion and takes no food; and the new formation of organs—especially those of locomotion and alimentation—which is necessitated by the totally different habits of the larva and mature insect, is also accomplished at the same period, largely, no doubt, at the expense of the material afforded by the disrupted larval organs. The larva itself does not form any of these organs and carry them about during its active life, though it does possess the very minute centres of growth known as the imaginal disks which burst into activity after the larval life is over. It must not be supposed that in all insects in which the sexual animal has a different habitat from the young form, there is a metamorphosis of the kind just described. In the may-flies and dragon-flies, in which the larva is aquatic, the change is prepared for some time before the actual metamorphosis, the organs which are necessary for the aerial existence being gradually acquired during larval life. In such cases, the metamorphosis belongs to our first type and consists of the act by which the organs previously and gradually acquired suddenly become functional. We have now considered in detail two typical cases of metamorphosis. In the first the change is gradually led up to and the larva is burdened, in its later stages at least, with organs which are of no use to it and only become functional at the metamorphosis. In the other, the change is not led up to. It is sudden, and a kind of second embryonic period is established.
METAMORPHOSIS

223

to enable the important and far-reaching transformation to be accomplished. It is clear that the two kinds of metamorphosis only differ in degree and that no line can be drawn between them.

In the Crustacea, as has already been pointed out, many authors apply the term metamorphosis to the whole larval development, which consists of a series of changes leading to the adult form. But this is in our opinion an incorrect use of the word. The typical larval development of a Crustacean consists of a series of small metamorphoses. At each moult new organs which have been developed since the preceding moult become manifest and some of them functional. For instance, the prawn *Penaeus* leaves the egg as a nauplius larva (fig. 3, A). It issues from the first moult as a metanauplius which has a forked tail, a beginning of the cephalo-thoracic shield, and a large helmet-shaped upper lip. It also possesses stump-like rudiments of the maxillae and two anterior pairs of maxillipeds. After the next moult it is known as a protozoaea (fig. 3, B), in which a cephalo-thoracic shield is well developed, the posterior part of the body is prolonged into a tail, in the anterior part of which the thoracic segments are obscurely indicated, and the four pairs of stump-like rudiments have become functional appendages (fig. 3, B (4), (5), (6), (7)). This passes into a later protozoaea stage (C) in which the rudiments of the compound eyes and of the abdominal segments are visible beneath the cuticle and in which certain functional changes (jointing, &c.) have appeared in the limbs. This is succeeded by the zoaea stage (fig. 3, D), characterized by the stalked and functional condition of the eyes, the increased size of the abdominal segments, and the appearance of appendages on the sixth of them, the increase of size in the third pair of maxillipeds (8) which had appeared as small rudiments in the preceding stage, and the appearance of the five pairs of posterior thoracic limbs as small biramous appendages. The zoaea stage is followed by the mysis stage (fig. 3, E) in which the thoracic feet are biramous, as in *Mysis*. From this the adult form proceeds. The transformation is more gradual than would be gathered from this short description, because moults

... occuring during the later stages from each of which the larva comes with some slight transformation.

In the life-history of a typical Cirripede there may be said to be two distinct metamorphoses, with gradual developmental stages taking place between them. The animal is hatched as a nauplius. This undergoes a series of moults during which increase in size and slight changes in form occur (fig. 4, A, B). At the last of them several organs characteristic of the second
or Cypris stage are discernible [fig. 5 (g), (6)] beneath the cuticle. When this is mouthed, the free-swimming cypris larva is libereted with its six pairs of biramous thoracic legs, its ringed antennae, and its paired compound eyes (fig. 6). This is the first metamorphosis. After a certain period of free life the Cypris larva attaches itself by its anterior antennae to some foreign object and enters upon the pupal stage (fig. 7). During this the larva takes no food and ceases to move, and undergoes important changes of structure and form beneath the larval cuticle, which invests it like a pupal case. These changes lead to the

When the larva are transformed, the shell-valves, is cast off and the young cirriped emerges. This is the second and final metamorphosis, which resembles in its main features the metamorphosis of the metamorphous Insecta.

The metamorphosis occurs in most groups of the animal kingdom. It is generally found in attached organisms, for these nearly always have free-swimming larvae and the metamorphosis occurs when the change of habit is effected. For the details of the process the reader is referred to systematic works on zoology. Here only the most striking instances of it can be mentioned. It occurs in a remarkable form in some sponges, in which at the metamorphosis the larval epidermis, which acts as a locomotive organ, is said to become transformed into the collared flagellated cells of the canal system, the adult epidermis being a new formation. It occurs in the Polyzoa, as well as in some of these, characterized by an almost complete disruption of the larval organs and a subsequent new formation of the organs of the adult. The metamorphosis in such cases belongs to our second type, the larval organs being entirely new formations and not developed from rudiments which make their appearance in the earlier larval history. In Phoronis the metamorphosis of the larva (Actinotrocha), which occurs on fixation, is gradually being lost, until the mode of destruction of some of the larval organs is peculiar; the brain and sense organs of the larva pass into the stomach and are digested. In the Tunicata, in which fixation of the free larva is effected by the head, as in Cirripedia and some, if not all, Polyzoa, the metamorphosis occurs entirely after fixation as a rapid series of developmental changes which occur ad hoc and are not prepared for by preceding changes. In Amphioxus there is no metamorphosis though the larvae changes are most remarkable and extensive, but the larval life is a long one and the development very gradual, the new organs coming into function as soon as they are formed.

In most Mollusca there is also a prolonged and important larval life, marked by very interesting stages of structure (trochosphere, veliger, &c.), but it is not usual to speak of a metamorphosis for the changes are gradual, each organ developing with great rapidity and coming into function at once. In certain forms, however, a metamorphosis occurs, e.g. in the glocophase larva of Anodonta, which embeds itself in the skin of a fish and there metamorphoses into the adult.

In the Echinodermata there is also a particular stage in the larval history, when the ciliary locomotive apparatus breaks up and is absorbed and the animal takes to its creeping life. This is the larval metamorphosis, which precedes larval development by changes to the complete establishment of the adult radial symmetry. The metamorphosis belongs therefore to our first

**METAPHOR—METAPHYSICS**

Fig. 8.—A ventral view of a dipnoan with carrying the body of the young starfish.

On the true order of the Aristotelian treatises see Aristot.
Philosophy” or “Theology,” which deals with being as being (Metaph. 1, 1, σερνεί ξηστήσις τις ήθελε το δο & υ πο θα το ην γενεύσα καθ' αύθη). From this phrase is derived the later term “Ontology” (q.v.). The misapprehension of the significance of some men and some views, come instead of the term “metaphysics,” e.g., for that which is concerned with the supernatural, not only by the schoolmen but even as late as 17th-century English writers, and within narrower limits the term has been dangerously ambiguous even in the hands of modern philosophers (see below). In the widest sense it may include both the “first philosophy” of Aristotle, and the theory of knowledge (in what sense can there be true knowledge?), i.e., both ontology and epistemology (q.v.), and this is perhaps the most convenient use of the term; Kant, on the other hand, would represent metaphysics as being “nothing more than the inventory of all that is given to us by pure reason, systematically arranged” (i.e., epistemology). The earliest “metaphysicians” concerned themselves with the nature of being (ontology), seeking for the unity which they postulated behind the multiplicity of phenomena (see IONIAN SCHOOL OF PHILOSOPHY and articles on the separate thinkers); later thinkers tended to inquire rather into the nature of knowledge as the necessary pre-requisite of ontological investigation. The extent to which these two attitudes have been combined or separated is discussed in the ensuing article which deals with the various schools of modern metaphysics in relation to the principles of the Aristotelian “first philosophy.”

1.—THE SCIENCE OF BEING

Side by side with psychology, the science of mind, and with logic, the science of reasoning, metaphysics is tending gradually to reassert its ancient Aristotelian position as the science of being in general. Not long ago, in England at all events, metaphysics was merged in psychology. But with the decline of dogmatic belief and the spread of religious doubt—as the special sciences also grow more general, and the natural sciences become more expansive about being and force, even the teleology—men begin to wonder again about the nature and origin of things, just as it was the decay of polytheism in Greek religion and his own discoveries in natural science which impelled Aristotle to metaphysical questions. There is, however, a certain difference in the way of approaching things. Aristotle emphasized being as being, without always sufficiently asking whether the things whose existence he asserted are really knowable. We, on the contrary, mainly through the influence of Descartes, rather ask what are the things we know, and therefore find less speculative about being and force, even the teleology, and in consequence come to treat metaphysics in relation to psychology and logic, from which epistemology is an offshoot.

To this pressing question then—What is the world as we know it?—three kinds of definite answers are returned: those of materialism, idealism and realism, according to the emphasis laid by metaphysicians on body, on mind, or on both. Metaphysical materialism is the view that everything known is body or matter; but while according to ancient materialists soul is only another body, according to modern materialists mind without body, there is no such distinction. Metaphysical idealism is the view that everything known is mind, or some mental state or other, which some idealists suppose to require a substantial soul, others not; while all agree that body has no different being apart from mind. Metaphysical realism is the intermediate view that everything known is either body or soul, neither of which alone exhausts the universe of being. Aristotle, the founder of metaphysics as a distinct science, was also the founder of metaphysical realism, and still remains its main authority. His view was that all things are substances, in the sense of distinct individuals, each of which has a being of its own different from any other, whereas an attribute has only the being of its substance (Met. Z 1–3; Post. An. 1. 4); that bodies in nature are obviously natural substances, and as obviously not the only kind of substance; and that there is supernatural substance, e.g., God, the perfect, imperishable being, thinking, but without matter, and therefore not a body.

At the present day realism is despised on the ground that its differentiation of body and soul, natural and supernatural, ignores the unity of being. Indeed, in order to oppose this unity of being to the realistic duality, both materialists and idealists describe themselves as monists, and call realists dualists by way of disparagement. But we cannot classify metaphysics by the antithesis of monism and dualism without making confusion worse confounded. Not to mention that it has led to another variety, calling itself pluralism, it confuses materialism and idealism. Extremes meet; and those who believe only in this, and those who believe only in mind, have an equal right to the equivocal term “monist.” Moreover, there is no real opposition between monism and dualism, for there can very well be one kind of being, without being all body or all soul; and as a matter of fact, Aristotelian realism is both a monism of substance and a dualism of body and soul.

It is in any case unfair to decide questions by disparaging terms, and to argue as if the whole choice were between materialist or idealist—between nothingness and everything. For so far as this it would also hide the truth of things, which requires two different kinds of substance, body and soul. The strength of materialism consists in recognizing nature without explaining it away, its weakness in its utter inability to explain consciousness either in its nature or in its origin. On the other hand, it is the virtue of idealism to emphasize the fact of consciousness, but its vice to exaggerate it, with the consequence of resorting to every kind of paradox to deny the obvious and get rid of bodies. There are in reality two species of substances or, better, two distinct things. Some who are impenetrably resisting, and those which are conscious substances and it is impossible to reduce bodies and souls to one another, because resistance is incompatible with the attributes of spirit, and consciousness inexplicable by the attributes of body. So far true metaphysics is a dualism of body and soul. But this very dualism is also monism: both bodies and souls are substances, as Aristotle said; and we can go farther than Aristotle. Men are apt to dwell too much on the co-existence and too little on the inclusiveness of substances. The fact is that many substances are often in one; e.g., many bodies in the one body, and body and soul in the one soul. We shall return, then, to the clearer and more authoritative division, and proceed to discuss materialism, idealism and realism in their order.

2.—MATERIALISM

1. Materialism Proper.—Materialism in its modern sense is the view that all we know is body, of which mind is an attribute or function. Several causes, beginning towards the end of the 18th century, gradually led up to the materialism of Molière, Vogt and Büchner, which flourished in the middle of the 19th century. The first cause was the rapid progress of natural science, e.g., the chemistry of Lavoisier, the zoology of Lamarck, the astronomy of Laplace and the geology of Lyell. These advances in natural science, which pointed to a unity and gradual evolution in nature, were accompanied by a growth in commerce, manufactures and industrialism; the same kind of spirit showed itself in the revolutionary upheaval of 1848, and in the materialistic publications which immediately followed, while these
publications have reacted on the industrial socialism of our own time. Meanwhile, philosophic forces to counteract materialism were weak. Realism was at a low ebb. Idealism was receding for the moment. Hegelianism had made itself unpopular, and its confusion of God, nature and man had led to differences within the school itself (see HEGEL). These causes, scientific, industrial and philosophical, led to the domination of materialism in the middle of the 19th century in Germany, or rather to its revival; for in its main position, that matter and motion are everything and eternal, it was a repetition of the materialism of the 18th century in France. Thus Karl Christopher Vogt (q.v.) repeated the saying of the French physicist Cabanis, "The brain is the stomach to digestion, or the liver to the secretion of bile," in the form, "Thought stands in the same relation to the brain as the bile to the liver or the urine to the kidneys." But the new materialism was not mere repetition. J. Moleschott (1822-1893) made a diligent use of the science of his day in his Kreislauf des Lebens (1852). Starting from Lavoir's discovery, he held that life is metabolism, a perpetual circulation of matter from the inorganic to the organic world; and back again, and he urged this metabolism against the hypothesis of vital force which had impelled all living beings to be a soul, though to plants only in the sense of a vegetative, not a sensitive, activity, and in Moleschott's time many scientific men still accepted some sort of vital principle, not exactly soul, yet over and above bodily forces in organisms. Moleschott, like Lotze, not only resisted the whole hypothesis of a vital principle, but also, on the basis of Lavoir's discovery that respiration is combustion, argued that the heat so produced is the only force developed in the organism, and that matter therefore rules man. He put the whole materialistic view of the world into the following form: Without matter no force, without force no matter. L. Büchner (q.v.) himself said that he owed to Moleschott the first impulse to composing his important work Kraft und Stoff (1855), which became a kind of textbook of materialism. Passing from Moleschott to Lyell's view of the evolution of the earth's crust and later to Darwin's theory of natural selection and environment, he reached the general inference that, not God but evolution of matter, is the cause of the order of the world; that life is a combination of matter which in favourable circumstances is spontaneously generated; that there is no vital principle, because all forces, both vital and non-vital, are movements; that movement and evolution proceed from life to consciousness; that it is foolish for man to believe that the earth was made for him, in the face of the difficulties he encounters in inhabiting it; that there is no God, no final cause, no immortality, no freedom, no substance of the soul; and that mind, like light or heat, electricity or magnetism, or any other physical fact, is a movement of matter. Sometimes he spoke of mind as an effect of matter; but, though his expressions may be careless, nothing is to be made of the difference, for he called it movement and effect indifferently in the same context. His definitely expressed view was that psychical activity is "nothing but a radiation through the cells of the grey substance of the brain of a motion set up by external stimuli." E. Haeckel belongs to a slightly later time than the materialists hitherto mentioned. His book Die Welträthel (Eng. trans. Biology and Philosophy) identifies substance with body. Starting like his predecessors with the indestructibility of matter, Haeckel makes more than they do of the conservation of energy, and merges the persistence of matter and energy in one universal law of substance, which, on the ground that body is subject to eternal transformation, is also the universal law of evolution. His strong point consists in inferring the fact of evolution of some sort from the consideration of the evidence of comparative anatomy, palaeontology and embryology. On the strength of the consience of arguments for evolution in the organic world, he carries back the process in the whole world, until he comes to a cosmology which recalls the rash hypotheses of the Presocratics.

He supposes that all organisms have developed from the simple cell, and that this has its origin by spontaneous generation, to explain which he propounds the "carbon-theory," that protoplasm comes from inorganic carboue, which condense first into centripetal face and Lyell's theory of the evolution of the solar system, but also supposes that the affinities, pointed out by Lothar Meyer and Mendeleeff, between groups of chemical elements prove an evolution of these elements from a primitive substance which condenses first into central forces and then into masses, which when they exceed the mean consistency become ponderables, and when they fall below it become imponderables. Here he stops; according to him substance is eternal; the force is temporary; and God is the eternal force or energy of substance. What, then, is the origin of mind or soul? Haeckel answers that it has no origin, because sensation is an inherent property of all substance. He supposes that actinium and trypois, as rudimentary sense and will, are the very causes of condensation; that they belong to pyknatoms, to ponderables and imponderables, to chemical atoms and molecules. Hence, when he returns to organisms, it does not surprise us that he assigns to ova and spermatzoa cell-souls, to the impregnated ovum germ-soul, to plants tissue-souls, to animals nerve-souls; or that he regards man's body and soul as born together in the fecundated egg, and gradually evolved the bodies and souls of lower animals. It appears to his imagination that the affinity of two atoms of hydrogen to one of oxygen, the attraction of the spermatozon to the ovum, and the elective affinity of a pair of lovers are all alike in the sense of a "soul" moving.

But has Haeckel solved the problems of mind? When he applies sensation and will to nature, and through plants to the lowest animals, he considers their sensation and will to be rudimentary and unconscious. Consciousness, according to his own admission, is not found even in all animals, although it is present not only in the highest vertebrates—men, mammals, birds—but also in ants, spiders, the higher crabs and molluscs. He has indeed thought, in accordance with the law of substance, that consciousness must be evolved from unconsciousness with the development of sense organs and a central nervous organ. At the same time he admits, firstly, that to mark the barrier between unconscious and conscious is difficult; secondly, that it is impossible to trace the first beginning of consciousness in the lower animals; and, thirdly, that "however certain we are of the fact of this natural evolution of consciousness, we are, unfortunately, not yet in a position to enter more deeply into the question" (Riddle of the Universe, 191). Thus in presence of the problem which is the crux of the whole question of consciousness he makes gratuitous hypothesis that everything has mind, and then gives up the origin of conscious mind after all. He is certain, however, that the law of substance somehow proves that conscious soul is a mere function of brain, that soul is a function of all substances, and that God is the force or energy, or soul or spirit, of nature. He, in fact, returns to a certain hylozoism (q.v.), which has tended to revive from time to time in the history of thought. He believes that mind and soul are inherent attributes of all bodies. Curiously enough, he supposes that by making mind a universal attribute of matter he has made his philosophy not materialism, but panmaterialism. It is really both: monistic, because it reduces substance to one kind; materialistic, because it identifies that one kind of substance with body or matter, and reduces mind to an attribute of matter. It makes no difference to attribute mind to all matter, so long as it is attributed as an attribute. It is at least as materialistic to say that unconscious mind is an attribute of nature as to say that conscious mind is an attribute of brain; and this is the position of Haeckel. Materialists seem to dread the word "materialism." Büchner also entertains us with the notion that we must replace the word "material" by another word, "substantial" (q.v.) and substitute "monism" for it (Last Words on Materialism, 273). His reason, however, is different: it is that a philosophy, not of matter as such, but of the unity of force and matter, is not materialism. But if a philosophy makes force an attribute of matter only, as his does, it will recognize nothing but matter possessing force, and will therefore be materialism as well as monism, and in short materialistic monism. The point is that neither Büchner nor Haeckel could on their assumptions recognize any force but force of
2. Materialistic Tendencies.—Besides these direct instances of materialism, there are philosophers to whom the scientific tendencies of the age have given a materialistic tendency. In Germany, for example, Eugen Dühring (q.v.) was a realist, whose intention is to prove against Kant a knowledge of the thing in itself by attributing time, space, and categories generally to the real world. But, under the influence of Trendelenburg's attempt to reconcile thought and being by assigning motion to both, his Wirklichkeitstheosophie, in a similar effort after a unity of being, lands him in the contention that matter is absolute being, the support of all reality underlying all bodily and mental states. So Avenarius (q.v.) was no materialist, but only an empiricist anxious to reclaim man's natural view of the world from philosophic incubations, yet when his Empiriokriticismus ends in nothing but environment, nervous system, and statements dependent on them, without soul, though within experience, he comes near to materialism, as Wundt has remarked. In it there is only positivism and not materialism, for his refusal to frame a metaphysical theory. Comte tells us that man first gets over theology, then over metaphysics, and finally rests in positivism. Yet in getting over theology he ceases to believe in God, and in getting over metaphysics he ceases to believe in soul. As Paul Janet truly remarked, positivism contains an unconscious metaphysics in rejecting final causes and an immaterial soul. Now, when in surrendering theology and metaphysics we have also to surrender God and the soul, we are not free from materialism. Positivism, however, shelters itself beneath the vague "unconscious" (unbewusst) (q.v.) and has thus managed to have not only an influence of positivism, but also, what is more important, the synthetic philosophy of Herbert Spencer. The point of this philosophy is not materialism, but realism. The author himself says that it is transfigured realism—which is realism in asserting objective existence as separate from subjective existence, but anti-realism in denying that objective existence is to be known. In his Principles of Psychology he twice quotes his point that "what we are conscious of as properties of matter, even down to its weight and resistance, are but subjective affections produced by objective agencies which are unknown and unknowable." This is, then, his transfigured realism, which, as far as what is known goes, is idealism, but as far as what exists goes, realism—of a sort. His First Principles, his book on metaphysics, is founded on this same point, that what we know is phenomena produced by an unknown noumenal power. He himself identifies phenomena, appearance, effect or impression produced on consciousness through any of the senses. He divides phenomena into impressions and ideas, vivid and faint, object and subject, non ego and ego, outer and inner, physical and psychical, matter and spirit; all of which are expressions of the same antithesis among phenomena. He holds that all the time, space, motion, matter known to us are phenomena; and that force, the ultimate of ultimates, is, as known to us, a phenomenon, "an affection of consciousness." If so, then all we know are these phenomena, affections of consciousness, subjective affections, but produced by an unknown power. So far as this main point of transfigured realism is steadily maintained, it is a compound of idealism and realism, but not materialism. But it is not maintained, on the side either of phenomena or of noumena; and hence its tendency to materialism.

In the first place, the term "phenomenon" is ambiguous, sometimes meaning "something known," and at others, "something unknown to us," by reason of the unknown power. Spencer himself finds to the laws of all phenomena. He finds that throughout the universe there is an unceasing redistribution of matter and motion, and that this redistribution constitutes evolution. When there is a predominant integration of motion and disintegration of matter, he calls it a "syntropic" or one-sided action. In that case, there is a difference between the phenomenon and the absolute affirmation, from the infinite to the definite, exemplified by the solar system with different bodies evolving into an order. He supposes that this evolution does not remain static, but becomes organic. In accordance with Lamarck's hypothesis, he supposes that evolution of organisms by hereditary adaptation to the environment (which happens according to necessity and even the possibility of an evolution of life, which, according to him, is the discontinuous adjustment of internal to external environment, he says, is analogous to how the mind obeyed the same law of evolution, and exemplifies integration by the adaptation by the development of the five senses, and determination by the development of the order of consciousness. He holds that with the development of animal life and the result of motion, the tendencies of mental life, that consciousness arises in the course of the living being's adaptation to its environment, and that there is a development of relation from reflex action through instinct and memory up to reason. He therefore holds that through a brilliant adaptation by the determination of the race is in a sense inherited by the individual; which is true in the sense that animal organisms become hereditarily better adapted to perform mental operations, though no proof that any of knowledge become a priori.

Now, Spencer has clearly, though unconsciously, changed the meaning of the term "phenomenon," from subjective affection of consciousness to any fact of nature, in regarding all the consciousness, organic, mental, social and ethical, as an evolution of phenomena. The greater part of the process is a change in the facts and in more consciousness produced in all that part of space, and the phenomena evolved must must move with the physical, not with conscious affections, but, as they develop, are causes which gradually produce life and consciousness. Moreover, evolution is defined as an "integument" (unbewusst) of matter and spirit, and yet mental, social and moral developments are also called evolution, so that, in accordance with the definition, they are also integral, not merely of matter and motion, but of consciousness, then to a change in social institutions, and finally into a change in moral motives. He also admits himself that mental activity and developments in matter and motion are chiefly only indirectly. But here he becomes hopelessly inconsistent, because he had already said, in defining it, that "evolution is an original production of motion and concomitant dissipation of motion" (First Principles, §145). However, with all the author's discrepancies, the general effect left on the reader's mind is that throughout the universe there is an unceasing change of matter and motion, that evolution is always such a change, that it begins with phenomena in the sense of physical facts, gradually issues in life and consciousness, and ends with phenomena in the sense of subjective affections of consciousness.

Moreover, in the second place, having declared the noumenal power, which causes phenomena, or conscious affections, to be unknowable, and having left anybody who pleased to make it a god and an object of worship, he proceeds to describe it as if it were known force, and known in its respect, and to that extent, which supposes that the law of evolution is deducible from the law of persistent force, and includes in force what is now called energy. Then he declares the evolved force to be a product of motion, which special emphasis on resistance, he tells us that "the force of which we assert persistence is that Absolute Force of which we are indefinitely conscious as the necessary correlate of the force we know" (First Principles, p. 62). Finally, in his Principles of Psychology, he assigns to us, in addition to our definite consciousness of our subjective affections, an indefinite consciousness of everything out of consciousness, of something which resists, of objective existence. Thus it turns out that the objective agency, the noumenal power, the absolute force, declared unknown and unknowable, is known after all to exist, persist, resist and cause our subjective affections or phenomena. It is not to think that the noumena looks very like body or matter. Lastly, when a theory of the world supposes a noumenal power, a resistant and persistent force, which results in an evolution, defined as an integration of motion and disintegration of matter, the result will be a resulted in an organic nature and organic nature, further results without break in consciousness, reason, society and morals, then such a theory will be construed as materialistically as that of Haeckel by the reader, who is not disposed to the "multiple endures the interpretation, and by adhering consistently to
Spencer's own materialistic definition of evolution; otherwise there will be a break at least in the life line of mind. If everything knowable is an example of a transformation of matter and motion, then everything knowable is an example of a transformation of matter and motion. As an exponent of universal evolution Haeckel is more consistent than Spencer.

Huxley (1825-1895) developed views very like those of Spencer, and similarly materialistic without being materialistic, because inconsistentable is an example of a transformation of matter, and reduced consciousness to a mere collateral product ("epiphenomenon") of cerebral operations without any power of influencing them. Matter, according to him, impresses the afferent nervous system, this the brain, this the effluent nervous system, while consciousness remains a mere spectator. "In man, as in brutes," he said, "there is no proof that any state of consciousness is the cause of change in the action of the matter of the organ upon itself," so that "we are conscious automatons." But, in spite of these materialistic tendencies, he followed Hume in reducing matter and everything knowable to phenomena of consciousness; and, supposing that nothing is knowable beyond phenomena, concluded that we can neither affirm nor deny that anything exists beyond, but ought to take up an attitude which the ancient sceptics called Aphasia, but he dubbed by the new name of Agnosticism. Thus Huxley first reduced consciousness to a product of matter, and then matter to a phenomenon of consciousness. By combining materialism with idealism he made consciousness a product of itself. Tyndall (1820-1893), on the contrary, came still closer to materialism and avoided it. In his Belfast address (1874), while admitting that matter as understood by Democritus is insufficient, because atoms without sensation cannot be imagined to produce sensation, he did, nevertheless, think properly understood is "the promise and potency of all terrestrial life." In thus endowing all matter with sensation like Haeckel he was not avoiding materialism, but in the very words of Haeckel, as well as in the conclusions, he did not identify mind with matter, but regarded them as concomitant.

All these materialistic tendencies seem to have one explanation. They emanate from scientists who rightly try to rise from science to metaphysics, but, as Bacon says, build a universal philosophy on a few experiments. The study of evolution, without considering how many conditions are required for the "integration of matter and the dissipation of motion" to begin, and the undoubted discoveries which have resulted from the study of inorganic and organic evolution, have made men to expect too much from this one law of Nature. This tendency especially prevails in biology, which is so far off the general principles of natural philosophy that its votaries are often ignorant of the real nature of body as matter and force. The close dependency of all mental operations on brain also tempts them to the conclusion that brain is not only an organ, but the whole organ of conscious mind. It appears also that Darwin, having extended his theory of evolution as far as the national and moral nature of man, in the Descent of Man, ended in his Anthropology by the same method as his predecessors, and thus confuted the whole basis of any materialistic conception that it is impossible to think of anything being to that of an agnostic. Not that he was a materialist, and shortly before his death, in a conversation with Büchner, he maintained his agnosticism against his opponent's atheism. Still, his agnosticism meant that, though he did not assert that there is no God, he did assert that we cannot know whether there is or is not. To the evolutionary biologist brain is apt to appear to be the crowning object of knowledge. On the other hand, scientific men, such as Herschel, Maxwell and Stokes, who aplicated the laws of mathematics to mechanics, and therefore from the universal laws of motion, have the opposite tendency, because they perceive that nature is not its own explanation. In order to exert force, or at all events that force of reciprocal pressure which we best understand, and on which, in impact, the third law of motion was founded, there are always at least two bodies, enduring, triply extended, mobile, each inert, mutually impenetrable or resistant, different yet similar; and in order to have produced any effect but equilibrium, some bodies must at some time have differed either in mass or in velocity; otherwise forces would simply have neutralized one another. Why do bodies exist, with all these conditions? It appears to be yet different—that is, in so harmonious an order? Natural science has no answer: natural theology has an answer. This essence of bodies, this resemblance in difference, this prevailing order of Nature, is the deepest proof of God; and it cannot be the result of evolution, because it is the condition of natural force, and therefore of natural evolution. A second argument for God is the prevailing goodness or adaptation of Nature to the ends of conscious beings, which might conceivably be explained by Lamarckian evolution, but has not yet been explained, and if it were, would not be inconsistent with a divine design in evolution. Further, the very existence of conscious beings is the best proof of the distinct or substantial being of the soul, existing in man with body, in God as pure spirit. It seems hopeless to expect that natural science, even with the aid of evolution, can explain by mere body the origin and nature of this fact of consciousness. If so, materialism is not the whole truth of metaphysics.

3.—THE RISE OF METAPHYSICAL IDEALISM

1. Descartes to Leibnitz.—Metaphysical arises from psychological idealism, and always retains more or less of an epistemological character. Psychological idealism assumes without proof that we perceive nothing but mental objects, and metaphysical idealism draws the logical and hypothetical conclusion that all we can know from these mental objects of sense is mental objects of knowledge. But at first this logical conclusion was not drawn. Descartes, the founder of psychological idealism, having proceeded from the conscious fact, cogito ergo sum, to the non sequitur that I am a soul, and all a soul can perceive is its ideas, therefore everything, neither body or soul, can exist alone. Descartes' conclusion that from these mental ideas I can (by the grace of God) infer things which are extended substances or bodies, as well as thinking substances or souls. He was a psychological idealist and a metaphysical realist. This illogicality could not last. Even the Cartesian school, as it came more and more to feel the difficulty of explaining the interaction of body and mind, and, and, indeed, any efficient causation whatever, gradually tended to the hypothesis that the real cause is God, who, on the occasion of changes in body, causes corresponding changes in mind, and vice versa. This occasionalism is not idealism, but its emphasis on the will of God gave it an idealistic tendency. Thereupon Spinoza advanced a pantheism which supposed that bodies and souls are not, as Descartes thought, different substances, but merely attributes—the one the extension and the other the thought of one substance, Nature or God. Taking the Aristotelian theory that a substance is a thing in itself, not in Aristotle's sense of any individual existing differently from anything else, but in the novel meaning of something existing alone, he concluded, logically enough from this understanding, that there can be only one substance, and that, as no finite body or soul can exist alone, the very finite is merely a mode of one of the attributes of the one infinite substance which alone can exist by itself. Spinozism, however, though it tramples down the barrier between body and soul, is not yet metaphysical idealism, because it does not reduce extension to thought, but only says that the same substance is at once extended and thinking—a position more akin to materialism. At the same time Spinoza maintained a parallelism between extension and thinking so close as to say that the order of ideas is the same as the order of things, so that any mode of extension is the same as any mode of thought, and vice versa, under the attribute of extension and under the attribute of thought (see H. H. Joachim's Study of the Ethics of Spinoza, 1907, p. 72). It remained, however, for Schelling to convert this parallelism into identity by identifying motion with the intelligence of God, and so to transform the pantheism of Spinoza into pantheistic idealism. Leibnitz, again, having become equally dissatisfied with Cartesianism, Spinozism and the Epicurean realism of Gassendi, in the latter part of his life came still nearer than Spinoza to metaphysical idealism in his monadology, or half-Pythagorean, half-Brunistic analysis of bodies into monads, or units, or simple substances, indivisible and unextended, but endowed with perception and appetite.

He gradually fell under the dominion of two false assumptions. On the one hand, essentially a mathematician, he supposed that
unity is indivisibility, whereas everything known to be one is merely undivided or individual, and that there must be simple because there are compound substances, although composition only requires something by the simplest of bodies. On the other hand, another idea of the mechanics of his day, which had hardly disinguished between inertia, or the inability of a body to change itself, and resistance or the ability of bodies to oppose one another, he concluded that there must be passive resistance, and his attempt to recognize that in collision the mutual resistance of moving bodies is a force, or active power, of changing their movements in opposite directions. From these two arbitrary hypotheses about corporeal motion, he concluded that particles are indivisibly simple elements, and that if it offers only passive resistance, he concluded that behind bodies there must be units, or monads, which would be at once substantial, simple, and passive. He further concluded that if the monads are "incorporeal automata," not interacting like bodies, but each receiving what was passing in the other, and acting in consequence by appetite, or self-acting. Such mentally endowed substances might be called souls; but, as he distinguished between perception and apperception or consciousness, and considered that perceptions are often unconscious, he preferred to divide monads into unconscious entities of the sort of bodily, sentient souls or animal and rational souls, or spirits, of men; while he further concluded that all these are derivative monads created by God, the monad of monads. All derivative monads, he allowed, are accompanied by their own self-perception; but monads composed of groups of monads are by a central monad. Further, he explained the old Cartesian difficulty of the relation of body and mind by transforming the Spinozian parallelism of extension and thought into a parallelism between the monads and the motions of the monads, or motions always preceding from motions, and perceptions from perceptions; bodies acting according to efficient causes, and souls according to efficient ideas and opinions of one body or soul without actually doing so. Finally, he explained the consciousness of these two series, as well as that between the perceptions of different monads, by supposing a pre-established harmony ordained by the primitive monad, God.

Up to this point, then, Leibnitz opened one of the chief avenues to metaphysical idealism, the resolution of the reality of the immaterial, the analysis of bodies into mental elements. His theory of bodies involved an idealistic analysis neither into bodily atoms nor into mathematical units, but into mentally endowed simple substances. There remained, however, his theory of the nature of bodies; and here he hesitated between two alternatives. According to one alternative, which consistently flowed from the psychological idealism of Descartes, as well as from his own monadism, he suggested that bodies are real phenomena; phenomena, because they are aggregates of monads, which derive their unity only from appearing together in the monads; the monads, however, are not real phenomena and result from real monads. In support of this view, he said that bodies are not substances, though substantialia; that their apparent motion and resistance are results of the passions of their monads; that their primary matter is nothing but passive power of their monads; that the series of efficient causes between them is merely phenomenal. According to this alternative, then, there is nothing but mental monads and mental phenomena; and Leibniz is a metaphysical idealist. According to the other alternative, however, he suggested that at least organic bodies are compound or corporeal substances, which are not phenomena; but something realizing or rather substantiating phenomena, and not mere aggregates of monads, but something substantial beyond their monads, because an organic body, though composed of monads, has a real unity (unio reals). From this point of view he believed that the real unity of a body is a vinculum substantialia, which gives it its real continuity and is the principle of its actions; that its primary matter is its own principle of resistance; and that it has not only this passive, but also an active, power of its own. He suggested that this theory of the substantial unity of a body might explain substantiation, by supposing that, while the monads and phenomena of bodies united, there is a kind of bond and constancy of the body of which the monads are the atoms.

He feared also whether we can explain the mystery of the Incarnation, and other substances, unless real bonds or unions are added to monads and phenomena. According to this alternative, these organic bodies are compound or corporeal substances, between monads and phenomena; and Leibnitz is a metaphysical realist. He held to this belief in the substantiability of bodies by his Christianity, by the influence of Aristotle, of scholasticism and of Cartesianism, as well as by his own mechanism. But the strange thing is that at the very end of his life and at the very same time, in 1714-1716, he was writing the idealistic alternative to Remond de Montmor and Dangcourt, and the realistic alternative to Father des Bosse. He must have died in doubt. We cannot, therefore, agree with many recent idealists who regard Leibnitz as one of themselves, though it is true that, when stripped of its realism, his metaphysics easily passed into the metaphysical idealisms of Lotze and of Fechner. It is true, also, that on its idealistic side the philosophy of Leibnitz is the source of many current views of psychophysical parallelism as well as of the phenomenalism of bodies, and of the analysis of bodies into mental elements.

2. Locke to Hume.—Meanwhile in England, Locke, though differing from Descartes about the origin of ideas, followed him in the illogical combination of psychological idealism with metaphysical realism. He thought that we perceive nothing but ideas both of primary and of secondary qualities, and yet that somehow we are able to infer that, while our ideas of secondary qualities are not, those of primary qualities are, like forms, the qualities of external things. Berkeley saw the inconsistency of this position, and, in associating himself with Locke and Hume and all we know is nothing but ideas in "mind, spirit, soul, or myself," has the merit of having made, as Paulsen remarks, "epistemological idealism the basis of metaphysical idealism." According to him, a body such as the sun is my idea, your idea, ideas of other minds, and always an idea of God's mind; and when we have sensible ideas of the sun, what causes them to arise in our different minds is no single physical substance, the sun, nor the will of God's spirit. Hume saw that in making all the force of perception ideas Berkeley had given as little reason for inferring substantial souls as substances. Berkeley, therefore concluded that all we know from the data of psychological idealism is impressions or sensations, ideas, and associations of ideas, making us believe without proof in substances and causes, together with "a certain unknown, inexplicable something as the cause of our perceptions." We have here, in this sceptical idealism, the source of the characteristically English form of idealism still to be read in the writings of Mill and Spencer, and still the starting-point of more recent works, such as Pearson's Grammar of Science and James's Principles of Psychology.

Kantianism and Fichtianism. As the result of his ideas, influenced by Leibnitz and partly raised by Hume, Kant elaborated his transcendental or critical idealism, which if not, as he thought, the prolegomena to all future metaphysics, is still the starting-point of most metaphysical idealists. Kantianism consists of four main positions, which it will be well to lay out, as follows:—

a. As to the origin of knowledge, Kant's position is that sense, outer and inner, affected by things in themselves, receives mere sensations or sensible ideas (Vorstellungen) as the matter which sense itself places in the a priori forms of space and time; that thereupon understanding, by means of the synthetic unity of apperception, "I think"—an act of spontaneity beyond sense, in all consciousness one and the same, and combining all my ideas as mine in one universal consciousness—and under a priori categories, or fundamental notions, such as substance and attribute, cause and effect, &c., unites groups of sensations or sensible ideas into objects and events, aubodies, one ball of fire, another of water, the sunrises, the sunsets, and so forth. Sense and understanding, requiring both sense and understanding, are partly a posteriori and partly a priori, and constitute a knowledge of objects which, being sensations combined by synthetic unity under a priori forms, are more than mere sensations, but less than things in themselves. This first position is psychological idealism in a new form and supported by new reasons; for, if experience derives its matter from mental sensations and its forms from mental synthesis, it follows that there is no matter but mental objects of sense, which, according to Kant, are sensible ideas having no existence outside our thought, not things in themselves. Kantianism and Fichtianism.

b. As to the known world, Kant's position was the logical deduction that from such phenomena of experience all we can know by logical reason is similar phenomena of actual or possible experience; and therefore that the known world, whether bodily or mental, is not a Cartesian world of bodies and souls, nor a Spinozistic world of one substance, nor a Leibnizian world of monadic substances.
created by God, but a world of sensations, such as Hume supposed, only combined, not by association, but by synthetic understanding into knowledge of objects of experience, which are phenomenal substances and causes—a world of phenomena not noumena. This second position is a new form of metaphysical idealism, containing the supposition, which lies at the foundation of later German phenomenology, of a world of objects of experience, which are phenomenal substances and causes—a world of phenomena not noumena.

As to existence, Kant's position is the wholly illogical one that, though all known things are phenomena, there are things in themselves, or noumena; things which are said to cause sensations of outer sense and to receive sensations of inner sense, though they are beyond the category of causality which is defined as one of the notions uniting phenomenal things, which things are assumed to exist and have three causal attributes, though declared unknowable by any logical use of reason, because logical reason is limited by the mental matter and form of experience to phenomena; and all this according to Kant himself. This third position is a relic of ancient metaphysical realism; although it must be remembered that Kant does not go to the length of Descartes and Locke, who supposed that from mere ideas we could know bodies and souls, but suggests that knowledge of the things in themselves is not heterogeneous (ungleichartig).

In this form we shall find the thing in itself revived by A. Riehl, in a reason beyond knowledge, Kant's position is this: that, in spite of its logical inability to transcend phenomena, reason in its pure, or a priori, use, contains necessary a priori "ideals" (Ideen), and practical reason, in order to account for moral responsibility as well as for the existence of objects, or noumena, corresponding to these "ideals"; postulates of a real free-will to practice morality, of a real immortality of soul to perfect it, and of a real God to crown it with happiness.

The fourth position is the coping-stone of Kant's metaphysics. It is quite inconsistent with its foundation and structure. Kant first deduced that from the experience of mental phenomena all logical use of reason is limited to mental phenomena, and then maintained that to explain moral responsibility practical reason postulates the existence of a thing in itself, and a posteriori the existence of things in themselves, or noumena, corresponding to these "ideals"; postulates of a real free-will to practice morality, of a real immortality of soul to perfect it, and of a real God to crown it with happiness.

Fichte now set himself in the Wissenschaftslehre (1794) to make transcendental idealism into a system of metaphysical idealism without Kant's inconsistencies and relics of realism.

His point was that there are no things in themselves different from minds or acting on them; that man is no product of things; nor does his thinking arise from passive sensations caused by things; nor is the end of his existence attainable in a world of things; but that he is the absolute free activity constructing his own world, which is only his own determination, his self-imposed limit, and means to his duty which allies him with God. In order to prove this novel conclusion he started afresh from the Cartesian "I think" in the Kantian form of the synthetic unity of apperception acting by a priori categories; but instead of allowing, with all previous metaphysicians, that the ego passively receives sensations from something different, and not contending with himself with Kant's view that the Ego, by synthetically combining the matter of sensations with a priori forms, produces its objects, he boldly asserted that the Ego, in its synthetic unity, entirely constructs things; that its act of spontaneity is not mere synthesis of passive sensations, but construction of sensations into an object within itself; and that therefore understanding makes as well as shapes Nature.

This construction, or self-determination, is what Fichte called positing (setzen). According to him, the Ego posits first itself (theses); secondly, the non-Ego, the other, opposite to itself (antithesis); and, thirdly, this non-Ego within itself (synthesis), so that all of these are the only possibilities (thesis, antithesis, synthesis). But if the Ego is conscious of this self-determining activity, but forgets itself, the non-Ego seems to be something independent, a foreign limit, a thing in itself, or per se. Hence it is a logical contradiction that the Ego posits things per se as only existing for itself, a nomenon in the sense of a product of its own thinking. Further, according to Fichte, on the one hand the Ego posits itself in its pure form as noumenon; this is the principal fact about theoretical reason; on the other hand, the Ego posits itself as determining the non-Ego—no subject, no object; this is the principal fact about practical reason. Hence he concludes that practical reason, which determines both, and is both with will, which Kant had distinguished; for he held that the Ego, in positing the non-Ego, posits both its own limit and its opposite, which things, as things, require will.

The conclusion of his epistemology is that we start with ourselves positing subjective sensations—e.g. sweet, red—and refer them as accidents to matter in space, which, though mental, is objective, because its production is grounded on a law of all reason.

The metaphysics resulting from this epistemology is that the so-called thing in itself is not a cause of our sensations, but a product of one's own thinking, a determination of the Ego, a thing known only by the Ego, which is the only thinkable and only existent idealism of Kant by identifying the thing with the object, and by interpreting nomenon, in Kant's sense of something to be determined from within, to exist not in accordance with the idea, but in the new meaning of a thought, a product of reason. This change led to another. Kant had said that the synthetic unity "I think" is in all consciousness of the self, and that the non-Ego is the opposite of this consciousness, or things known. Fichte transformed this unity of the conscious self into a unity of all conscious selves, or a common consciousness; and this change enabled him to explain the thing being produced by pure reason, containing that it is not the different objects of different thinkers, but the one object of a pure Ego or consciousness common to them all. According to Kant, the objective is valid for all consciousnesses; according to Fichte it is valid for the Ego.

Thus the complete metaphysical idealism of Fichte's Wissenschaftslehre formed out of the incomplete metaphysical idealism of Kant's Kritik is the theory on its epistemological side that the Ego posits the non-Ego as a thing in itself, and yet as only a thing existing for itself and on its own account, that in consequence all reality is the Ego and its own determinations, which are objective, or valid for all, as determinations, not of you or of me, but of a non-Ego, or the self-conception of the consciousness of a non-Ego. Lastly, Fichte called this system realism, in so far as it posits the thing in itself as another thing; idealism, in so far as it posits it as a nomenon which is a product of its own thinking; and on the whole real idealism or ideal realism.

God does not seem to find much place in the Wissenschaftslehre, where mankind is the absolute and nature mankind's product, and where God neither could be an absolute Ego which posits objects in the non-Ego to infinity without ever completing the process, nor could be even known to exist apart from the moral order which is man's destination. Hence in his Philosophical Journal in 1795 Fichte produced a scathing essay of Schelling by an essay of his own, in which he uses the famous words, "The living moral order is God; we need no other God, and can comprehend no other." Having, however, in consequence, lost his professorship and his婚后, his new religious and political activity was decided that God is not mere moral order, but also reason and will, yet without consciousness and personality; that not mankind but God is the absolute, that we are only its direct manifestations, free but finite spirits destined by God to positt in ourselves nature as the material of duty, but blessed when we relapse into the absolute; that Nature, therefore, is the direct manifestation of God, and that man, and not God, determines Nature: this is the final outcome of Fichte's pure idealism.

Fichte completed the process from psychological and epistemological to metaphysical idealism, which it has been necessary to
recall from its beginnings in France, England and Germany, in order to understand modern idealism. The assertion of absolute substance by Spinoza incited Schelling and Hegel. The analysis of body into humors and his own liberal metaphysics expanded the mental in the universal. In this way, Kant's conception of noumena was the absolute product of synthesis. They rightly revolted against the inconsistencies of Kant's third and fourth positions about the existence of unknown but postulated things in themselves, hidden from theoretical, but revealed to practical, reason. In a way they returned to the older opinions of Aristotle, which had come down to Descartes and Locke, that reason in going beyond sense knows more things than phenomena; yet they would not hear of external bodies, or of bodies at all. No realists, they came nearer to Spinozistic pantheism and to Leibnizian monadism, but only on their idealistic side; for they would not allow that extension and body are different from thinking and mind. Their idealism was Fichte, on account of his definite reduction of the noumenal to the mental. This was indeed the very point—the knowability of a noumenal mental world. At the same time it soon appeared that they could not agree among themselves when they came to ask what it is, but in attempting to define it seemed to have gone through the whole gamut of mind. Schelling and Hegel thought it was infinite reason; Schopenhauer, unconscious will; Hartmann, unconscious intelligence and will; Lotze, the activity or life of the divine spirit; Fechner, followed by Paulsen, a world of spiritual actualities comprised in the one spiritual actuality, God, in whom we live and move and have our being.

1. Of these noumenal idealisms the earliest in time and the nearest to Fichte's philosophy was the panlongism, begun by Schelling (1775-1854), completed by his disciple Hegel (1770-1831), and then modified by the master himself. Starting from Fichte's "Wissenschaftslehre," Schelling accepted the whole process of mental construction, and the deduction that noumena are knowable products of universal reason, the Absolute Ego. But from the first he went beyond Fichte, and had no doubt that the Absolute is God, as he thought, is universal reason, and Nature a product of universal reason, a direct manifestation, not of man, but of God. How is this Absolute known? According to Schelling it is known by intellectual intuition. Kant had attributed to God, in distinction from man's understanding, an intellectual intuition of things. Fichte had attributed to man an intellectual intuition of himself as the Absolute Ego. Schelling attributes to man an intellectual intuition of the Absolute; and as there is, according to him, but one universal reason, the common intelligence of God and man, this intellectual intuition at once gives man an immediate knowledge of God, and identifies man with God himself.

On Schelling's idealistic pantheism, or the hypothesis that there is nothing but one absolute reason identifying the opposites of subjectivity and objectivity, Hegel based his panlongism. But, while he fully recognized his indebtedness to his master, he differed from him profoundly in one fundamental respect. He rightly objected that the system was wanting in logical proof. He rightly, therefore, rejected the supposed intellectual intuition of the Absolute. He rightly contended that, if we are to know anything beyond sense, we must know it by a process of logical reason. But, unfortunately, he did not mean the logical inferences described in the Organon and the Novum organum. He meant a new "speculative" method, dialectic, founded on an assumption which he had already learnt from Schelling, namely, that things which are different but similar can have the same attribute, and therefore be also the same. With this powerful instrument of dialectic in hand, he attempted to show how absolute reason differentiates itself into subjective and objective, ideal and real, and yet is the identity of both—an identity of opposites, as Schelling had said. By the same dialectic Hegel was able to justify the gradual transformation of transcendent into noumenal idealism by Fichte and Schelling. If things different but similar have the same attributes, and are thereby the same, then in the first place the Kantian categories, though thoughts of mental origin and therefore confined to mind, are nevertheless applicable
The plain answer is to contest the whole assumption. Different things, however, must have only different attributes, can never be the same. God created man in His own image, and the world in the image of the Divine Idea; but I am not God, and the transitory sun is not the same as God's eternal idea of it. The creatures, however like, are not the same as the Creator and His thoughts. Each is a distinct thing, as Aristotle said. Reality is not Reason. It is strange that the underlying assumption of panphilosophy was not at once corrected in this plain way. Nevertheless, objection was soon taken to the unsatisfactoriness of the system reared upon it. Schelling himself, as soon as he saw his own formulæ exposed in the logic of the other dialectic, with his disciple Fichte, he began to realize of himself, and brought some powerful objections against both the conclusions and the method of Hegel. Schelling perceived that Hegel, in reducing everything to infinite mind, absorbed man's free but finite personality in God, and, in declaring that everything real is rational, failed to explain evil and sin: indeed, the English reader of T. H. Green's Prolegomena to Ethics can see how awkward is the Hegelian transition from "one spiritual principle" to different men's individual freedom of choice between good and evil. Again, Schelling urged that besides the rational element there must be something else; that there is in nature, as nature naturans, a blank intellectual idea belonging to itself, and that even God Himself as the Absolute cannot be pure thought, because in order to think He must have an existence which cannot be merely His thought of it, and therefore pure being is the prior concept of all intelligence and spiritual nature. Schelling's Hegelian dialectic on the ground that, although reason by itself can apprehend notions or essences, and even that of God, it cannot determine the existence either of one or of the other, of which an apprehension of which experience is required. He now distinguished two philosophies: negative philosophy starting from notions, and positive philosophy starting from being; the former a philosophy of conditions, the latter a philosophy of the absolute; only the former, had only supplied the logic of negative philosophy; and it must be confessed that the most which could be extracted from the Hegelian dialectic would be some connexion of thoughts without proving any existence of corresponding things. Schelling was right; but he had too much affinity with Hegelian assumptions, e.g. the panlogical confusion of the essences of things with the notions of reason, to meet the objection of the existence of a divinity which is, outside of all things, a free and unlimited will, and which at the same time lies on the activity of will, he resembled Fichte. His theory of the nature of will was his own, and arrived at from a voluntaristic psychology leading to a voluntaristic metaphysics of his own. His psychological starting-point was the unproved assumption that the only force of which we are immediately aware is will; his metaphysical goal was the consistent conclusion that in that case the only force we can know, as the noumenal essence of which all else is phenomenal appearance, is will. By this noumenal will he did not mean the holy and merely divine will as identical with our Spirit, or rather with the Infinite Spirit, or Absolute Reason, which alone exists. The crux of all metaphysical idealism is the difficulty of reconciling the unity of the object with the plurality of subjects. Hegel's assumption of identity in difference at once enabled him to deal with the whole difficulty by holding that different subjects are yet one subject, and any one object, e.g. the sun, is at once different from, and identical with, the one subject which is also many. By the rough magic of this modern Prospero the universe of being is not, and yet is, thought, idea, spirit, reason, God. So elastic a solution established a dominant Hegelian school, which is now practically extinct, in Germany, and from Germany spread Hegelianism to France, England, America, and, in fact, diffused it over the civilized world to such an extent that it is still a widespread fashion outside Germany to believe that the world of being is a world of thought.

3. The First to modify the pure voluntarism of Schopenhauer was E. von Hartmann, who (Die Philosophie des Unbewussten, 1869, 1st ed.), advanced the view that the world as noumenal is both unconscious intelligence and unconscious will, thus founding a panpantheism which forms the basis of reconciliation between a voluntaristic and pantheistic of Schopenhauer. In his tract titled Schelling's positive Philosophie als Einheit von Hegel und Schopenhauer (1869) he further showed that, in his later philosophy, Schelling had already combined reason and will in the Absolute. Indeed, Fichte had previously characterized the life of the Absolute by reason and will without consciousness; and, before Fichte, Leibnitz had asserted that the elements of Nature are monads with unconscious perception and appetite. Hartmann has an affinity with all these predecessors, and with Spinoza, whom he agrees that there is but one substance unaltered by the plurality of what are only modes. Following, however, in the footsteps of Schelling, he idealizes the one extended and thinking substance into one mental being; but he thinks that its essence consists in unconscious intelligence and will, of which all individual intelligent wills are only activities. The merit of this fresh noumenal idealism consists in its correction of the one-sidedness of Schopenhauer; intelligence is necessary to will. But Hartmann's criticism does not go far enough. He ends by outdoing the paradox of Schopenhauer, concluding that Nature in itself is intelligent will, but unconscious, a sort of immanent unconscious God.

As with his master, his reasons for this view are derived, not from a direct proof that unconscious Nature has the mental attributes of a substantial person, but from the assumption that every mental feeling, like Leibnitz, he proceeds from the fact that our perceptions are
sensible phenomena. But while he was in fundamental agreement with the first two positions of Kant, he differed from the third; he did not believe that the causes of sensible phenomena can be unknown things in themselves. What then are they? Lotze retained the Leibnizian fallacy that ultimate causes are necessary, which led to the Leibnitzian analysis of material bodies into immaterial monads, indivisible and therefore unextended, and to the theory of monadic souls and entelechies. Indeed, from the time of Leibnitz such attempts either to analyse or to construct matter had become a fashion. Lotze agreed with Leibnitz that the things which cause phenomena are immaterial elements, but added that they are not simple substances, self-acting, as Leibniz thought, or preserving themselves against disturbance, as Herbart thought, but are interacting modifications of the one substance of God.

In the first place, he resolved the doubt of Leibnitz about bodies by deciding entirely against his realistic alternative that an organic body is a substantia realisans phaenomena, and for his idealistic alternative that every body is a phenomenon and not a substance at all, and that the immaterial elements without accepting their self-action. He believed in reciprocal action; and the very essence of his metaphysics consists in supposing some interaction of the immaterial elements, which produce effects on one another and are causally connected as one of them. According to the mechanics of Newton, when two bodies collide each makes the other move equally and instantaneously. He illustrated this in concrete by the interaction of bodies exchanged motion as men do money. Now Lotze took this abstract language literally, and had no difficulty in showing that, as an attribute is not separated from its substance, this supposed communication of motion docs not really take place; nothing passes. But instead of returning to the concrete fact of the equivalence of momentum, by which each body moving makes the other move oppositely, he denied that bodies do reciprocally act on one another, and even that bodies as mutually resisting substances are the subject agents in collision. Having thus rejected all body mechanism, he had to suppose that reciprocal action somehow takes place between immaterial elements. This brought him to another difference from Leibnitz as well as from Newton. According to Leibnitz, while each immaterial element is a monadic substance and self-acting secondary cause, God is the primary cause of all. According to Lotze, the connexion required by reciprocity requires also that the whole of every reciprocal action should take place within one substance; the immaterial elements act on one another merely as the modifications of that substance interacting within itself, and that one substance is God, who thus becomes not merely the subject agent in collision, but the object agent as well. Nothing passes. But still, as in his criticisms of the antithesis of monadic substances, he flew to the Spinozistic unity of substance, which, he argued, if we are to attribute to him, the one substance, God, is not extended at all, and is not merely thinking, but is a thinking, willing and acting spirit.

Lotze's metaphysics is thus distinguished from the theism of Newton and Leibnitz by its pantheism, and from the pantheism of Spinoza by its idealism. It is an idealistic pantheism, which is a denial of all bodily mechanism, a reduction of everything bodily to phenomena, and an assertion that all real action is the activity of God. At the same time it is a curiously attempted to restore mechanism and reconcile it with teleology by using the word "mechanism" in a new meaning, according to which God performs His own reciprocal actions within Himself by uniform laws, which are also means to divine ends. It is also an attempt to reconcile this divine mechanism with freedom. In his Metaphysik (1879), as in his earlier Mikrokosmos (1856-1864), Lotze vindicated the contingency of freedom by assigning to God a miraculous power of unconditional commencement, whereby not only at the very beginning but in the course of nature there may be new beginnings, which are not effects of previous causes, though they are modifications of substance according to law. Thus his pantheistic is also a teleological idealism, which in its emphasis on free activity and moral order recalls Leibnitz and Fichte, but in its emphasis on the infinity of God has more affinity to Spinoza, Schelling and Hegel. Hence his philosophy, like the Hegelian, continually torments one with the difficulty that its sacrifice of the distinct being of
all individual substances to the universality of God entails the sacrifice of the individual personality of men. Our bodies were reduced by Lotze to the general ruck of phenomenal appearances. Our souls he tried his best to endow with a quasi-existence, arguing that the unity of consciousness requires an indivisible subject, which is distinct from the plurality of the body but interacting with it, is in a way a centre of independent activities, and is so far a substance, or rather able to produce the appearance of a substance. But at the end of his *Metaphysik* from the conclusion that everything beyond phenomena is divine interaction, he drew the consistent corollary that individual souls are simply actions of the one genuine being. His final view was that certain actions of the divine substance are during consciousness gifted with knowledge of themselves as active centres, but during unconsciousness are non-existent. If so, we are not persons with a permanent being of our own distinct from that of God. But in a philosophy which reduces everything to phenomenal appearance except the self-interacting substance of God, there is no room for either the bodies or the souls of finite substances or human persons.

5. Fechner (1801–1887) affords a conspicuous instance of the idealistic tendency to mysterize nature in his Panpsychism, or that form of noumenal idealism which holds that the universe is a vast communion of spirits, souls of men, of animals, of plants, of earth and other planets, of the sun, all embraced as different members in the soul of the world, the highest spirit—God, in whom we live and move and have our being; that the bodily and the spiritual, or the physical and the psychical, are everywhere parallel processes which never meet to interact; but that the difference between them is only a difference between the outer and inner aspects of one identical psychophysical process; and yet that both sides are not equally real, because while psychical and physical are identical, the psychical is what a thing really is as seen from within, the physical is what it appears to be to a spectator outside; or spirit is the self-appearance of matter, matter the appearance of one spirit to another. Fechner's panpsychism has a certain affinity both to Stahl's animism and to the hylozoism of materialists such as Haeckel. But, while it differs from both in denying the reality of body, it differs from the former in extending conscious soul not only to plants, as Stahl did, but to all Nature; and it differs from the latter in the different consequences drawn by materialism and idealism from this universal animism. According to Haeckel, matter is the universal substance, spirit its universal attribute. According to Fechner, spirit is the universal reality, matter the universal appearance of spirit to spirit; and they are identical because spirit is the reality which appears. Hence Fechner describes himself as a twist fallen from Schelling's tree. Schelling's adherent Oken by his *Lehrbuch der Naturphilosophie* conveyed to his mind the life-long impression that God is the universe and Nature God's appearance. At the same time, while accepting the Schellingian parallelistic identity of all things in God, Fechner was restrained by his accurate knowledge of physics from the extravagant construction of Nature, which had failed in the hands of Schelling and Hegel. Besides, he was deeply impressed by the fact of man's personality and by the problem of his personal immortality, which brought him back through Schelling to Leibnitz, whose *Monadologie* throughout maintains the plurality of monadical souls and the omnipresence of perception, sketches in a few sections (§§ 23, 78–51) a panpsychic parallelism, though without identity, between bodily motions and psychic perceptions, and, what is most remarkable, already uses the conservation of energy to argue that physical energy pursues its course in bodies without interacting with souls, and that motions produce motions, perceptions produce perceptions. Leibnitz thus influenced Fechner, as in other ways he influenced Lotze. Both, however, used this influence freely; and, whereas Lotze used the Leibnitzian argument from indivisibility, in which he found indivisible elements and souls, Fechner used the Leibnitzian hypotheses of universal perception and parallelism of motions and perceptions, in the light of the Schellingian identification of physical and psychical, to evolve a world-view (Weltansicht) containing something which was neither Leibnitz nor Schelling.

Fechner's first point was his panpsychism. Emphasizing the many real analogies between the physical and psychical, he sought much stronger evidences that all the mental operations of men and animals require a nervous system, he flew to the paradox that soul is not limited to men and animals, but extends to all other to the sun, to the world itself, of which, according to him, God is the world-soul. In this doctrine of universal animation he was like Leibnitz, yet very different. Whereas Leibnitz confined a non-existent soul to its immediate body, Fechner extended consciousness to the whole world; and accordingly, the soul of the world pursues to the whole world, in which the Schellingian becomes the "Entelechies," *Leibnitz* extended consciousness to the whole world; and accordingly, the soul of the world pursues to the whole world, in which the Schellingian becomes the "Entelechies," the substance of the whole, and "Entelechies" is a word of the same meaning. Fechner, in the spirit of Schelling, identified God with the soul of the world. Fechner's second point was that, throughout the animated universe, physical processes and psychic processes are in constant interaction. In his panpsychic parallelism he was again like Leibnitz, and he developed his predecessor's view, that the conservation of energy prevents interaction, into the supposition that alongside the physical there is a parallel psychical conservation of energy. Here, again, he went much further than Leibnitz, but along with Schelling, in identifying the physical and the psychical as outer and inner sides of the same thing, in which the Schellingian becomes the "Entelechies." According to Fechner's third point he carried him beyond all his predecessors, containing in it the doctrine of his 'world-view.' He advanced the ingenious suggestion that, as body is in body and all perceives in its own way, so soul perceives in its own way in the world-soul. By this means he explained immortality and individuated personality. His fourth point was connected with this inclusion of perception in the highest arts as in the highest. It is his so-called "synchronological view." Fechner and Lotze, both deeply affected by the Leibnitzian hypothesis of indivisible monads, supposed that man's soul is seated at a central point in the brain, where, by the supposition of the thing, is necessary to explain the unity of consciousness. Fechner's supposition was that the unity of consciousness belongs to the unity of the whole body; that the seat of the soul is the living body; that the soul changes its place as it affects or parts a process rises along the "threshold of consciousness"; and that soul is not substance but the single psychological life which has its physical manifestation in the single bodily life. Applying this "synchronological view," he took the inclusion of soul in soul, he deduced the conclusion that, as here the nature of one's soul is to unite one's little body, so hereafter its essence will be to unite a greater body, while God's spirit unites the whole world by His omnipresence; and he pertinently asked, in opposition to the "punctal" view, whether God's soul is centred in a point. Lastly, the whole of this "world-view," was developed by Fechner in early life, under the influence of his religious convictions, which led him out of the narrow field of Christianity which teach us that we are children of God, that this natural body will become a spiritual body, and that, though we are disintegrated into that spiritual body, we still remain as individuals; and in De vivisco, movemus, et sumus. It is important to notice that Fechner maintained this "world-view" in a little book, *Das Buchlein vom Leben nach dem Tode*, which he originally published in 1849. In 1849 the government condemned the book and the author was ordered to withdraw it, and his name was also placed on the *index*. The work, however, was republished in his own name in 1866, and again in 1887, as a sketch of his *Weltansicht*. Afterwards in *Nanna* (1845) he discussed the supposed souls of plants, and in *Zedawesta* (1851) the supposed souls of the earth and the rest of the world. Then in 1855 he published his *Altonenlehre*, partly founded on his physics, but mainly on his metaphysics. Under the influence of Leibnitz, Boscovich, Kant and Fichte he supposed that bodys were atoms, which are not bodies, but centres of forces of attraction and repulsion; that impenetrability is a result of repulsive force; and that force itself is only law—taking as an instance that Newton's laws of attraction and repulsion in his process we do not understand, and neglecting that Newtonian force of pressure and impact whose process we do understand from the collision of bodies already extended and resisting. But, in thus adapting to his own purposes the Fichtean analysis of物质, he entirely ignored the Fichtean conclusions to his own metaphysics, which required that the supposed centres of force are not Leibnitzian monads, as the second metaphysics he afterwards supposed, but are elements of a system which in outer aspect is bodily and in inner aspect is spiritual, and obeying laws of spirit. At the same time his synchronological view prevented him from adapting to his own purposes Newton's view that every soul always corresponds to a unity of a physical manifold. Thus his metaphysics is Leibnitzian, like that of Lotze, and yet is opposed to the most characteristic feature of monadology—the percipient intrinsic monad.

In 1860 appeared Fechner's *Elemente der Psychophysik*, a work which deeply affected subsequent psychology, and almost revolutionized our conception of body and soul, and our ideas of mental relations generally. It becomes necessary, therefore, to determine
how far Fechner derived his psychophysics from experience, how far from fallacies of inference, from his romantic imagination and from his theosophic metaphysics, which indeed coloured his whole book on psychophysics. At the very outset he started with his previous maxim, that sensations are many, and that the psychical is parallelism with the physical.

He now compared the spiritual and bodily sides of a man to the concave and convex sides of a circle, as inner and outer sides of the same process, which is psychical as viewed from within and physical as viewed from without. He maintained, much as he did before, that physical and psychical energy do not interfere, but that the psychical, like a mathematical quantity, a function of the physical, depending on the latter for its values, and the psychical in no manner determines the physical. According to law, we may conclude from one to the other, but without one ever being cause of the other. By his psychophysics he meant the exact doctrine of the relations of dependence of sensations as thus defined, and which is in accordance with the principle of causality, as his aim was not to frame the doctrine of the relations of the spiritual and psychical, but to determine the relations between the physical stimuli and the so-called "intensity" of sensations. He generalized Weber's law (q.e.), in the form that sensation generally increases in intensity as the stimulus increases by a constant function of the previous or increases in an arithmetical progression as the stimulus increases in a geometrical ratio; or increases by the same amount as the stimulus increases by the same multiple; or increases as the logarithm of the stimulus increases. There are more explanations of moderate sensations, concomitant variations between stimuli and sensations, not only in "quality," as in the intervals of sounds, which were understood long ago, but also in "intensity" by the latter than by the former. They do not distinguish the law of the subjective stimulus given by Weber, the inverse square of the physical stimulus, and that of the objective stimulus given by Fechner's law. The rules of induction from concomitant variations, we are logically bound to infer the realistic conclusion that outer physical stimuli increase inner sensations, and inner sensations increase outer stimuli. The conclusion is certainly desired for Fechner, the very opposite conclusion followed from the pre-suppositions of his parallelistic metaphysics, and from the Leibnitian view of the conservation of energy, which he was the first in our time to assert that man and the animal kingdom is a concomitant, and a psychical effect, on the ground that physical energy must be exactly replaced by physical energy.

Having satisfied himself in what he called "outer psychics," he then proceeded to resolve the neural process and neglected to pass to what he called "inner psychics," or the theory of the relation between nervous and psychical processes. He rightly argued against the old theory that the continuity of nervous process, that the train is interrupted by mental processes of thought and will: there is a nervous process for every mental process. But two questions then arose. What is the relation between nervous process and sensation? What causes sensation? The first question he answered from his imagination by supposing that, while the external world is stimulus of the nervous process, the nervous process is the immediate stimulus of the sense, and that the sensation is produced by the previous impression of the nervous system in the nervous system, when Weber's law proves only that it increases by a constant fraction of the previous stimulus in the external world. The second question he answered from his knowledge of psychophysical metaphysics, by declaring that within the organism there is only an apparent dependency of sensation on nervous process without causation because the nervous process is physical but the sensation psychical. There is, he says, the psychical accompaniment, the action of the external stimulus on the nervous system to the reaction of the organism on the external world is one series, while the conscious process beginning with sensation is only parallel and as it were, high and dry. What then is the cause of the sensation? Huxley, it will be remembered, in similar circumstances, answered this question by degrading consciousness to an epiphenomenon, or by product of the physical process. Fechner was saved from this absurdity, but only to fall into the greater absurdity of his own panpsychism. Having long assumed that the whole world is animated throughout, and that there are always two parallel series, physical and psychical, he now concluded that such processes as are causing a physical nervous process, a psychical accompaniment of the stimulus is causing the sensation, which, according to him, is the psychical accompaniment of the nervous process; and that, as in the parallel series, so in the nervous, the psychical differing only as outer and inner, this identity holds both of stimulus and its psychical accompaniment and of nervous process and its accompanying sensation. Accordingly, he calls these and all other processes, his as well as other organisms, "psychical energies, physical and psychical, differing only as outer and inner aspects of the same energy, he called this "psychophysical energy." In his "Theorie der Erscheinungen," p. 91, he said: "The idea of psychical and physical energies, physical and psychical process are the same, it is the psychical which is the reality of which the nervous is mere appearance; and so everywhere, spirit is the reality, the body the appearance of spirit to spirit. Finally, he supposed that one spirit is in another, and all in the highest spirit, God. By this means also he explained unconsciousness. In point of fact, many stimuli are beneath the "threshold" of a man's conscious. Leibnitz, in the "Neuen Essays," ii, had also said that his high idea of spirituality, which he had about the physical and psychical, was very unconscious, and had further suggested that a perception of which we are, is composed of a quantity of "petites perceptions" of which we are not conscious. Proceeding on this suggestion, and misled by his psychological and theosophical metaphysics, Fechner held that a conscious sensation, like its stimulus, consists of units, or elements, by summation and increments of which consciousness is built up. Inasmuch as unconsciousness, according to this unnecessary assumption, emerges from an integration of unconscious shocks or tremors. But by the hypothesis of the inclusion of spirit in spirit, he was further able to frame the doctrine that one spirit is the unconscious spirit, while everything whatever is in the consciousness of the highest spirit of God, who is the whole reality of which the spirits are parts, while the so-called physical world is merely outer appearance of one spirit to another.

Fechner first confused physics and metaphysics in psychophysics, and next proceeded to confuse them again in his work on evolution ("Neue Theorie der Schaffungs- und Entwicklungsgeschichte der Organismen," 1873). He perceived that Darwinism attributed too much to accident, and was also powerless to explain the origin of life and of consciousness. But his substitute was his own hypothesis of parallelism, that the one and the other was produced, as it were, from a "cosmogonic" or original condition of the world as a living organism into the inorganic, by the principle of tendency to stability, to unity. But he put his "cosmogonic" theory, as he puts on its physical side, always was a living body; and on its psychical side, Fechner's aristeism and stereism, and, so far from life arising from the lifeless, and consciousness from unconsciousness, the life and consciousness of the whole world are the product of its unconsciousness. He erected a psychological doctrine of secondary automatism, while we ourselves are developed from our own mother-earth by differentiation. By thus supposing a psychical basis to evolution, Fechner, anticipating Wundt, substituted a psychical development of organs for Darwinian accidental variation. The difficulty of such speculations is to prove that things apparently dead and mindless are living souls. Their interest to the metaphysician is in the opposition to physics on the one hand and to theology on the other. Shall we resign our traditional belief that the greatest part of the world is mere body, but that its general adaptability to conscious organisms proves its creation and government by God, and take to the new hypothesis, which, by a transfer of design from God to Nature, supposes that everything physical is alive, and conducts itself by psychical impulses of its own? Fechner himself went even further, and together with design transferred God Himself to Nature. This is the subject of his latest metaphysical work, "Die Tagesansicht gegenüber der Nachtansicht" (1879). The "day-view" (Fechner's) is the view that God is the psychophysical all-embracing spirit of the universe; the "night-view" (Wundt's) is the world view of Hegel and Lotze in its pantheistic tendency. But it does not, like theirs, sacrifice our personality; because, according to Fechner, the one divine consciousness includes us as a larger circle includes smaller circles. By supposing the consciousness of one spirit in another, Fechner's "day-view" also puts Nature in a different position; neither with Hegel sublimating it to the thought of God's mind, nor with Lotze degrading it to the phenomena of our physical nature. But he also transferred the former appearance of one spirit to another spirit in the highest of spirits.

We have dwelt on this curious metaphysics of Fechner because it contains the master-key to the philosophy of the present moment. When the later reaction to Kant arose against both Hegelianism and materialism, the nearly contemporary appearance of Fechner's Psychophysik began to attract experimental psychologists by its real as well as its apparent exactness, and both psychologists and metaphysicians by its novel way of putting the relations between the physical and the psychical in man and in the world. Fechner saw psychology deriving advantage from the methods, as well as the results, of his experiments, and in 1879 the first psychological laboratory was erected by Wundt at Leipzig. But he had also to endure countless objections to his mathematical statement of Weber's law to his unnecessary assumption of units of sensation, and to his unjustifiable transfer of the law from physical to physiological stimuli of sensations, involving in his opinion his parallelistic view of body and mind. Among psychologists Helmholtz, Mach, Brentano, Hering, Delboeuf, were all more or less against him. Sigwart in his Logic also opposed the parallelistic view itself; and James has criticized it from the point of view that the soul selects out of the possibilities of the brain means to its own ends. Nevertheless, largely under the influence of the exaggeration
of the conservation of energy, many psychologists—Wundt, Paulsen, Richl, Joll, Ebbinghaus, Münsterberg, and in England Lewes, Clifford, Romanes, Stout—have accepted Fechner's psychophysical parallelism, as far at least as men and animals are concerned. Most stop here, but some go with Fechner to the full length of his metaphysical parallelism of the physical and psychical, as psychophysical, throughout the whole world. Things extended from Germany to Denmark, where it was embraced by Höolding, and to England, where it was accepted by Romanes, and in a more qualified manner as "a working hypothesis" by Stout. But the most thorough and most eloquent of Fechner's metaphysical disciples was F. Paulsen (q.v.), who spread panpsychism far and wide in his Einleitung in die Philosophie.

Here reappear all the characteristic points of Fechner's "world-view"—the panpsychism, the universal parallelism with the identification of physical and psychical, the inclusion of spirit with the soul. In spirit, in the synchronological view of spirit, and this "day-view" that all reality is spirit, and body the appearance of spirit to spirit. But Paulsen tries to supply something wanting in Fechner. The originality of Paulsen consists in trying to supply an epistemological explanation of the metaphysics of Fechner, by reconciling him with Kant and Schopenhauer. He borrows from Kant's "idealism" the hypothesis of a spontaneous activity of the soul, on the condition that this activity begins from within and arises from understanding; and he accepts from Kant's metaphysical idealism the consequence that everything we perceive, experience and know about physical nature, and the bodies of which it consists, is conditioned by a corresponding thing existing within ourselves. Thus arises a different theory of human nature and soul, and so does not accept the Kantian conclusion that things in themselves, in the sense of things beyond phenomena, are all unknowable. On the contrary, his contention is that of Fechner—that all knowable things are inner psychical realities beneath outer physical appearances—the invisible symbolized by the visible. Kant, however, had no epistemological foundation for his contention, because according to him it was not even outer, but inner senses give more appearance, from which we could not know either body in itself, or soul in itself. Parting, then, from Kant, Paulsen resorts to a paradox which he shares with Fechner and Wundt. He admits, indeed, Kant's hypothesis that by inner sense we are conscious only of mental states, but he contends that this very consciousness is a knowledge of a thing in itself. He agrees with Fechner and Wundt that there is no substantial soul, and that soul is nothing but the mental states, or rather their unity—thus identifying it with Kant's synthetic unity. On this assumption he deduces that in being conscious of our mental states we are conscious of them as appearing to us, but not as in itself, and therefore can infer similar souls, other psychical unities, which are also things in themselves.

What is the essence of this psychical reality which we thus indirectly and mediately know? Here he appeals to Schopenhauer's doctrine that will of some sort is the fundamental fact of mental life. Taking, then, will to be the essential thing in itself of all knowables, he deduces that the inner psychical things in themselves beyond ourselves are also essentially "will." Combining with this the central dogma of Fechner that spirit extends throughout the world of bodily appearance, he concludes that the realities of the world are "will," that bodies are mere appearances of "will," and that there is one universal all-embracing spirit which is "will." His ultimate metaphysics, then, is this: Everything is spirit, and spirit is "will." Lastly, by "will" he does not mean "rational desire," which is its proper meaning, but inapplicable to Nature; nor unconscious irrational will, which is Schopenhauer's forced meaning; nor unconscious intelligent will, which is Haeckel's more primitive, though inapplicable to Nature. His "will" is instinct, impulsive feeling, a "will to live," not indeed unconscious, but often subconscious, without idea, with only a fleeting end and a vague purpose. Thus, in short, what he calls, after K. E. von Baer, Zitelsträbigkeit, How persistent is ancient animism! Empedocles, Plato and Aristotel; Telesto, Bruno and Campanella; Leibniz; the idealists, Schopenhauer and Hartmann, Fechner and Paulsen; and the materialist Haeckel—all have agreed in a kind of accord to Nature. So prone are men to exaggerate adaptation into aim! So prone are men to transfer to the physical the providence God! (see Bacon, De augmentis, iii, 4, sub fin.).

Nominal idealism is not dead in Germany. It died down for a time in the decline of Hegelianism, and the rise of materialism. It has, however, passionately declared in its last hours. The panpsychism of Schelling and Hegel survives in its influence. So still more does the pantheism of Schopenhauer. The three most vital idealisms of this kind at the moment are the panpneumatism of Hartmann, combining Hegel with Schopenhauer; the pantheologism of Lotze, revising Leibnitz; and the panpsychism of Paulsen, continuing Fechner, but with the addition of an epistemology combining Kant with Schopenhauer. All these systems of metaphysics, differ as they may, agree that things are known to exist beyond sensible phenomena, but yet are mental realities of some kind. Meanwhile, the natural substances of Aristotelian realism are regarded with common aversion.

5.—PHENOMENAL IDEALISM IN GERMANY

Phenomenal idealism is the metaphysics which deduces that, as we begin by perceiving nothing but mental phenomena of sense, so all we know at last from these data is also phenomena of sense, actual or possible. So far it is in general agreement not only with Hume, but also with Kant in his first two positions. But it follows Fichte in his revolt against the unknown thing in itself. On the other hand, as the speculative systems of phenomenal idealism, starting from Fichte, succeeded one another, like ghosts who "come like shadows, so depart," without producing conviction, and often in flagrant opposition to the truths of natural science, and when, in consequence, a wave of materialism threatened to submerge mind altogether by reducing it to a function of matter, many philosophers began to despair of the ambitious attempts which had been made to prove that there is a whole world of mind beyond phenomena, as the nominalists had supposed. Thus they were thrown back on the limits of human knowledge described by Kant, but purged of the unknown thing in itself by Fichte. Phenomenal idealism is, therefore, the Kantian contention that Nature, as known to science, is phenomena of experience. Unfortunately, the word "phenomenon" is equivocal (see Mind, xiv, 309). Sometimes it is used for any positive fact, as distinguished from its cause. But sometimes it means what appears, or can appear, to the senses, as distinguished from what does not appear, but can be inferred to exist. Now, Kant and his followers start from this second and narrower meaning, and usually narrow it still more by assuming that what appears to the senses is as mental as the sensation, being unidentifiable from it or from the idea of it, and that an appearance is a mental idea (Vorstellung) of sense; and then they conclude that we can know by inference nothing but such mental appearances, actual and possible, and therefore nothing beyond sensory experience. When, on the other hand, the objects of science are properly described as phenomena, what is meant is not thisittance of sensible appearances, but positive facts of all kinds, whether perceptible or imperceptible, whether capable of being experienced or of being inferred from, but beyond, experience, e.g. the farther side of the moon, which is known to exist, and thus to Kant, that Nature as known to science is phenomena means one thing in Kantism and another thing in science. In the former it means that Nature is mental phenomena, actual and possible, of sensory experience; in the latter it means that Nature is positive facts, either experienced or inferred. It is most important also to notice that Kantism denies, but science asserts, the logical power of reason to infer actual things beyond experience. But the phenomenal idealists have not, any more than Kant, noticed the ambiguity of the term "phenomenon," they fancy that, in saying that all we know is phenomena in the Kantian sense, and that Nature as known to science is phenomena, they are describing all the positive facts that science knows; and they follow Kant in supposing that there is no logical necessity of actual things beyond experience.

1. The Reaction to Kant.—The reaction to Kant ("Zurück zu Kant") was begun by O. Liebmann in Kautz und die Epigenon (1865). Immediately afterwards, in 1866, appeared Lange's Geschichte des Materialismus. In 1870 J. B. Meyer published his Kants Psychologie, and in 1871 H. Cohen his more important Geschichte des Idealismus. Lange (q.v.) by his History of Materialism has exercised a profound influence, which is due partly to its apparent success in answering materialism by Kantian arguments, and partly to
its ingenious attempt to give to Kantism itself a consistency, which, however, has only succeeded in producing a new philosophy of Neo-Kantism, differing from Kantism in modifying the a priori and rejecting the thing in itself. Lange to some extent modified the transcendentalism of Kant’s theory of the origin of knowledge. A priori forms, according to Kant, are contributions of the mental powers of sense, understanding, and reason; but, according to Lange, they are rooted in “the physico-psychical organization.” This modification was the beginning of a gradual lessening of the antithesis of a priori to a posteriori, until at last the a priori forms of Kant have been transmuted into “auxiliary conceptions,” or “postulates of experience.” But this modification made no difference to the Kantian and Neo-Kantian deduction from the epistemological to the metaphysical. Lange entirely agreed with Kant that a priori forms can have no validity beyond experience when he says: “Kant is at any rate so far justified as the principle of intuition in space and time a priori is in us, and it was a service to all time when he in this first great example, show that what we possess a priori, just because it arises out of the disposition of our mind, beyond our experience has no longer any claim to validity” (Hist. of Materialism, trans. E. C. Thomas, ii. 203). Hence he deduced that whatever we know from sensations arranged in such a priori forms are objects of our own experience and mental phenomena. Hence also his answer to materialism. Science, says the materialist, proves that all known things are material phenomena. Yes, rejoins Lange, but Kant has proved that material are merely mental phenomena; so that the answer to the psychological reality, and the more surely he is playing into the hands of the idealist— an answer which would be complete if it did not turn on the equivocation of the word “phenomenon,” which in science means any positive fact, and not a mere appearance, much less a mental appearance, to sense and sensory experience. Having, however, made a deduction, which is at all events consistent, that on Kantian assumptions all we know is mental phenomena, Lange proceeded to reduce the rest of Kantism to consistency. But his ardent love of consistency led him far away from Kant in the only way he succeeded consistently from the assumption, that whatever we think beyond mental phenomena is ideal, to the logical conclusion that in practical matters our moral responsibilities cannot prove the reality of a noumenal freedom, because, as on Kant’s assumption we know ourselves from inner sense only as phenomena, we can prove only our phenomenal freedom. Lange thus transmuted inconsistent Kantism into a consistent Neo-Kantism, consisting of these reformed positions: (1) we start with sensations in a priori forms; (2) all things known from these data are mental phenomena of experience; (3) everything beyond is idea, without any corresponding reality being knowable. "The intelligible world," he concluded, "is a world of poetry." Our reflection is that there is a great difference between the essence and the consistency of Kant’s philosophy. Its essence, as stated by Kant, was to reduce the logical use of reason to mental phenomena of experience in speculation, in order to extend the practical use of reason to the real noumena, or things in themselves, required for morality. Its consistency, as deduced by Lange, was to reduce all use of reason, speculative and practical, to its logical use of proceeding from the assumed mental data of outer and inner sense, arranged a priori, to mental phenomena of experience, beyond which we can conceive ideas but postulate nothing. As H. Valentin (p. 322) tells us to a profound Kantian of the new school, says: "Critical scepticism is the proper result of the Kantian theory of knowledge.”

There is only one Neo-Kantian way out of this dilemma, but it is to alter the assumptions of common psychology. This is the alternative of A. Riehl, who in Der philosophische Kriseitsrieh (1876, &c.) proposes the non-Kantian hypothesis that, though things in themselves are unknowable through phenomena, they are knowable by empirical intuition, and therefore also by empirical thought starting from intuition. Like all true followers of Kant, Riehl prefers epistemology to metaphysics; yet in reality he founds a metaphysics on epistemology, which he calls “critical realism,” so far as it asserts a knowledge of things beyond phenomena, and "critical monism," so far as it holds that these things are unlike both physical and psychical phenomena, but are nevertheless the common basis of both. He accepts the Kantian postulate of unity of consciousness as the a priori synthesis, and that therefore all that natural science knows about matter moving in space is merely phenomena of outer sense; because, he says, that from these data we could not infer things in themselves by reason. But he denies that the sensation of phenomena or appearances implies the things which appear. Sensory knowledge, he says, "is the knowledge of the things which are in the world of phenomena, but he proposes to extend it to the realm of things of the external world as objective in the Kantian sense of universally valid. He interprets the external world to be the common root of physical phenomena, which he rightly relies on the numerous passages, neglected by Lange, in which Kant regards things in themselves as neither phenomena nor ideas, but things existing beyond both. But his main reliance is on the passage in the Kritik, where Kant, speaking of the Cartesian difficulty of communication between body and soul, suggests that, however body and soul appear to be different in the phenomena of outer and inner sense, what lies as thing in itself the basis of the phenomena of both may perhaps be not so heterogeneous. Riehl elaborates this broad suggestion into the metaphysical theory that the single basis of physical and psychical phenomena is necessarily non-psychical, not simply not psychical, to give the metaphysical meaning to "critical monism," he accepts to a certain extent the psychophysical philosophy of Fechner. He agrees with Fechner that physical perception, sense and mental and psychical processes of mind are really the same psychical processes. The mind of the one hand to an observer and on the other hand to one’s own consciousness; and that physical phenomena only produce physical sensations to that the awareness of this causes, and not that physical stimuli produce sensations. But whereas Fechner and Paulsen hold that all physical processes are universally accompanied by psychical processes which are the real causes of psychical sensations. Riehl rejects this paradox of universal parallelism in order to fall into the equally paradoxical hypothesis that something or other, which is neither physical nor psychical, causes both the physical phenomena of space, time and consciousness, and the psychical phenomena of mind to arise in us as its common effects. In making a direct perception of such a non-descriptive thing, he shows to what straits idealists are driven in the endeavour to supplement Kant’s doctrine of knowledge to phenomena by some sort of knowledge of things.

2. The Reaction to Hume.—When the Neo-Kantians, led by Lange, had modified Kant’s hypothesis of a priori forms, and retracted Kant’s admission and postulation of things in themselves beyond phenomena and ideas, and that without proceeding further in the direction of Fichte and the noumenal idealists, there was not enough left of Kant to distinguish him essentially from Hume. For what does it matter to metaphysics whether by association sensations suggest ideas, and so give rise to ideas of substance and causation a posteriori, or only by the unity of consciousness combines sensations by a priori notions of substance and causation into objects which are merely mental phenomena of experience, when it is at once allowed by the followers of Hume and Kant alike that reason in any logical use has no power of inferring things beyond the experience of the reasoner? In either case, the effective power of inference, which makes us rational beings, is gone. Naturally then the reaction to Kant was followed by a second reaction to Hume, partly under the name of “Positivism,” which has attracted a number of adherents, such as C. Goring (1841-1879), author of an Incomplet System der Kritischen Philosophie (1847-1853) and E. Lias (p. 73), and partly under the name of “physical phenomenology” of E. Mach.

Ernst Mach (p. 74) is a conspicuous instance of a confusion of physics and psychology ending in a scepticism like that of Hume. He tells us how from his youth he pursued physical and psychological studies, how at the age of fifteen he read Kant’s Prolegomena, and later rejected the thing in itself, and came to the conclusion that the world with his ego is one mass of sensations. For a time, under the influence of Fechner’s Psychophysik, he thought that Nature has two sides, a physical and a psychological, and added that all atoms have feeling. But the progress of his physical work, which taught him, as he thought, to distinguish between what we see and what we
mentally supply, he soon passed from this noumenalism to a "universal physical phenomenology." It retains some relics of Fechner's influence; first, the theory of identity, according to which the difference between the physical and psychical is not a dualism, but everything is at once both; and secondly, the substitution of mathematical dependence for physical causality; that, whereas Fechner only denied causality between physical and psychical, Mach rejects the entire distinction between causality and dependence, on the ground that "the law of causality simply asserts that the phenomena of Nature are dependent on one another." He comes near to Hume's substitution of succession of phenomena for real causality. He holds, like Hume, that nothing is real except our sensations and complexes of sensory elements; that the ego is not a definite, unalterable, sharply bounded unity, but its continuity alone is important; and that we know no real causes at all, much less real causes of our sensations; or, as he expresses it, bodies do not produce sensations, but complexes of sensations form bodies. If he has any originality, it consists in substituting for the association of ideas the "economy of thinking," by which he means that all theoretical conceptions of physics, such as atoms, molecules, energy, &c., are mere helps to facilitate our consideration of things. But he limits this power of mind beyond sensations to mere ideas, and like Hume, and also like Lange, holds at last that, though we may form ideas beyond sensations or phenomena, we cannot know things. Hence, he was led to this scepticism, which is contained in his well-known scientific work Die Mechanik in ihrer Entwicklung (1883; ed. 1908) as well as in his psychological work on the Analysis of Sensations (Beiträge zur Analyse der Empfindungen, 1886), we find two main causes, both psychological and epistemological; namely, his views on sense and on inference. In the first place, he displays in its most naked form the common but unproved idealistic paradox of a sense of sensations, according to which touch apprehends not pressure but a sensation of pressure, sight apprehends not colour but a sensation of colour, and there is no difference between the sensory operation and the sensible object apprehended by any sense, even within the sentient organism. Hence, according to him, sensations are not apprehensions of sensible objects (e.g. pressures felt) from which we infer similar objects beyond sense (e.g. similar pressures of outside things), but are the actual elements out of which everything known is made; as if sensations were like chemical elements. Within the limits of the supposed sensory elements he accords more than many psychologists do to sense; because, following the nativists, Johannes Müller and Helmholtz, he includes sensations of time and space, which, however, are not to be regarded as "pure intuitions" in the style of Kant. But here again he identifies time and space with the sensations of them (Zeit-empfindungen and Raumempfindungen). On the assumption, then, that time and space are not objects, but systems, of sensations, he concludes that a body in time and space is "a relatively constant sum of touch-and-light-sensations, joined to the same time-and-space-sensations," that each man's own body is included in his sensations, and that to explain sensations by motions would only be to explain one set of sensations from another. In short, sensations are elements and bodies complexes of these elements. Secondly, his theory of inference contains the admission that we infer beyond sensations: he remarks that the space of the geometer is beyond space-sensations, and the time of the physicist does not coincide with time-sensations, because it uses measurements such as the rotation of the earth and the vibrations of the pendulum. But by inference beyond sense he does not mean a process of concluding from sensible things to similar things, e.g. from tangible pressures to other similar pressures in the external world. Inference, according to him, is merely mental completion of sensations; and this mental completion has two characteristics: it only forms ideas, and it proceeds by an "economy of thought." In the course of his learned studies on the history of mechanics he became deeply impressed with Galileo's appeals to simplicity as a test of truth, and converted what is at best only one characteristic of thinking into its essence. According to him, whatever inferences we make, certain or uncertain, are mere economies of thought, adapting ideas to sensations, and filling out the gaps of experience by ideas; whatever we infer, whether bodies, or molecules, or atoms, or space, or time, is immediately affected by the conditions of thought; and "bodies or things are comperative mental symbols for groups of sensations—symbols which do not exist outside thought." Moreover, he applies the same scepticism to cause and effect. "In Nature," says he, "there is no cause and no effect."] He thinks that repetitions of similar conjunctions occur in Nature, the connexion of cause and effect only in abstraction. He refers to Hume as recognizing no causality but only a customary and habitual succession, but adds that Kant rightly recognizes the mere delection cannot meet the necessity of the conjunction. But in reality his theory is his theory of association nor Kant's of an a priori notion of understanding under which a given case is subsumed. He thinks that there is a notion of understanding (Verstehensbegriff), under which every new experience is subsumed, but that it has been developed by former experience, instinctively, and by the development of the race, as part of the economy of thinking. "Cause and effect are therefore," he concludes, "thought-things of economical function (Gedankenverwendung in ökonomischer Funktion)." His philosophy, therefore, is that all known things and sensations and complexes of sensory elements, are subsumed by an economy of thinking which cannot carry us beyond ideas to real things, or beyond relations of dependency to real causes. It is important to understand that Mach had developed this economical view of thought in 1872, more than ten years before the appearance of his work on the history of mechanics Kirchhoff. as he tells us in the preface, where he adds that at a later date similar views were expressed by Kirchhoff in his Vorlesungen über mathematische Physik (1874). Kirchhoff asserted that the whole object of mechanics is "to describe the motions occurring in Nature complete as it can be, in a manner," which involves the denial of force as a cause, and the assertion that all we know about force is that the acceleration of one mass depends on that of another, as in mathematics a function depends on a variable; and that even Newton's third law of motion is merely a description of the fact that two material points determine in one another, without reciprocally causing, opposite accelerations. It is evident that Kirchhoff's descriptive is the same as Mach's economical view. "When I say," says Mach, "that a body A exerts a force on a body B, I mean that B, on coming into contraries, produces accelerations and complexes of sensory elements, in the acceleration with respect to A." In a word, Mach and Kirchhoff assert that force is not a cause, convert Newtonian reciprocal action into mere interdependency, and, in old terminology, reduce mechanics from a natural philosophy of causes to a natural history of mere facts. Now, Mach applies these preconceived opinions to "mechanics in its development," with the result that, though he shows much skill in mathematical mechanics, he misrepresents its development precisely at the critical point of the discovery of Newton's third law of motion.

The true order of discovery, however, was as follows:—

(a) Sir Christopher Wren made many experiments before the Royal Society, which were afterwards repeated in a corrected form by Sir Isaac Newton in the Principia, experimentally proving that bodies of accelerated comparative weights, when suspended and impelled against one another, forced one another back by impressing on one another opposite changes of velocity inversely as their weights and therefore masses; that is, by impressing on one another equal and opposite changes of momentum.

(b) Wallis showed that such bodies reduce one another to a joint mass with a common velocity equal to their joint moment divided by their mutual mass.

(c) Wren and Huygens further proved that the law of equal action and reaction, already experimentally established by the former, was deducible from the conservation of the velocity of the common centre of gravity, which is the same as the common centre of masses, that is, deducible from the fact that their common centre
of gravity does not change its state of motion or rest by the actions of the bodies between themselves; and they further extended the law to bodies, qua elastic.

Metaphysics

Aristotelianists, in their deduction from the original laws of motion, and adding further instances from attractive forces of magnetism and gravity, induced the third law of motion as a general law of all forces.

This order of discovery shows that the third law was generalized far beyond the limits of any of its discoverers. In his short paper on "The Elasticity of Weights and Masses," it is not material points or mass-points. It shows that the bodies impact on one another opposite changes of velocity inversely as their weights or masses; and that in doing so they are always by mutual interaction of mutual inertial velocities to begin with, apart from the subsequent effects of elasticity.

(c) Newton in the Principia, repeating and correcting Wren's elastic hypothesis, and adding further instances from attractive forces of magnetism and gravity, induced the third law of motion as a general law of all forces.

Of this discovery shows that the third law was generalized far beyond the limits of any of its discoverers. In his short paper on "The Elasticity of Weights and Masses," it is not material points or mass-points. It shows that the bodies impact on one another opposite changes of velocity inversely as their weights or masses; and that in doing so they are always by mutual interaction of mutual inertial velocities to begin with, apart from the subsequent effects of elasticity.

The two bodies therefore do not penetrate one another, but begin by acting on one another with a force sufficient, instead of penetrating one another, to cause them to form a joint mass with a common velocity. Bodies then are triply extended substances, each occupying enough space to prevent mutual penetration. The laws of consciousness of individual consciousnesses, resistance cause one another to form a joint mass with a common velocity when they collide. This foundation of bodies is a factor inter-reaction forces causing one another in collision to form a joint mass with a common velocity; and the evidence of the third law disappears; for in the case of attractive forces, we know nothing of their modus operandi except by the attraction. The mutual interaction of Newton's will only be of mutual velocities, not of their common velocity, whatever they may do afterwards in consequence of their elasticities. The two bodies therefore do not penetrate one another, but begin by acting on one another with a force sufficient, instead of penetrating one another, to cause them to form a joint mass with a common velocity. Bodies then are triply extended substances, each occupying enough space to prevent mutual penetration.

He has therefore lost sight of the truths that bodies are triply extended, mutually impenetrable substances, and by this cause which reduce one another to a joint mass with a common velocity, and causally connected, and causally connected to other minds.

He has therefore lost sight of the truths that bodies are triply extended, mutually impenetrable substances, and by this cause which reduce one another to a joint mass with a common velocity, and causally connected, and causally connected to other minds.

In Great Britain Mach's scepticism was welcomed by Karl Pearson to support an idealistic phenomenology derived from Hume, and by Ward to support opposition to Wundt's experimentalism. However, phenomenology in metaphysics can take place, and natural science itself is in some danger, until the true history of the evidence of the laws of mechanics.

It is not easy to give a conclusion that what we know is not material points determining one another's opposite accelerations, but bodies by force of impenetrable force causing one another to keep apart. Mechanics is a natural philosophy of causes.

3. Dualism within Experience.—Besides those philosophies which are reactions to Kant or to Hume, there are a number of other modern systems which start with the common hypothesis that knowledge is experience. The consequence is that whatever is true of experience they transfer to all knowledge. One of the characteristics of actual experience is that its object is, or has been, present to an experiencing subject; and of possible experience that it can be present. As a matter of fact, this characteristic differentiates experience from inference. By inference we know that things, such as the farther side of the moon, which not only are not present to the consciousness, but are remote or impossible of presence, are objects of knowledge, being objects of experience, are, or have been, or can be, present to an experiencing subject. Hence it is common nowadays to hold that there is indeed a difference between knower and known, ego and non-ego, subject and object, but that they are inseparable; or that all known things are objects and subjects inseparably connected in experience. This view, however, is held in different forms; and two opposite forms have arisen in Germany, "immanent philosophy" and "empirio-criticism," the former nearer to Kant, the latter to Hume.

Immanent Philosophy is the hypothesis that the world is not transcendent, but immanent. Its adherents are the view of this are Anton von Leclay, who expresses it in the formula "Denn es einen Seins gedacht Phraseology, W. von Schuppe, who says that every fragment of the pretended transcendent belongs to the immanent. But the best known representative of Immanent Philosophy is W. Schuppe, who, in his Erkennnissrheoretische Logik der Erfahrung (1849), gives the view the wider scope by the contention that the real world is the common content or object of common consciousness, according to him, as according to Fichte, is one and the same in all individual conscious entities, and their understandings not only differ in having each its own content, in which Schuppe includes each individual's body as well as the rest of the things which come within the consciousness of each; but they also as plainly agree, e.g. in all admitting one sun. Now, the point of Schuppe is that, so far as they agree, individual consciousnesses are not merely similar, but the same in essence; and this supposed one and the same piece of consciousness in all individuals is consciousness in general (Becusstein überhaupt). While in this identification he follows Fichte, in other respects he is more like Kant's "immanent" philosophy. This common content is partly a posteriori, or consisting of given data of sense experience. Though the content of understanding, which, being valid for all objects, are contributed by the common consciousness. He differs, however, from Kant in the intransitive relation which will not allow that the given data are received from things in themselves, but also because, like Mach, he agrees with the materialist that the data already contain a spatial determinancy and a temporal determinancy, which he regards as a posteriori elements of the given, not like Kant, as a priori forms of sense. He allows, in no a priori forms except categories of the understanding, and these he reduces, considering that the most important of them the categories of understanding, which in his view are necessary to the judgments that the various data which make up a total impression (Gesammeindruck, Totalindruck) are each different from the others, together identical with the total ideality of the actual world, which is the data of the common consciousness, and coexistence. At the same time, true to the hypothesis of "immanence," he rigidly confines these categories to the given data, which avoid the inconsistent tendency of Kant to transfer causality from a necessary relation between phenomena to a necessary relation between phenomena and things in themselves as their causes. Hence he strictly confines true judgment and knowledge to the consciousness of the identity or difference, and the casual relations of the given content of the common consciousness. From this epistemology he derives the metaphysical conclusion that the things we know are indeed independent of my consciousness and of the space and time in which we are conscious. The argument that bodies are triply extended, mutually impenetrable substances, and by this cause which reduces one another to a joint mass with a common velocity, and causally connected, and causally connected to other minds.

The "empirio-criticism" of M. Avenarius (1854) is the hypothesis of the insubstantiality of subject and object, and, to use his own phraseology, of ego and environment, in purely empirical, or posteriori, form. It is like "immanent philosophy," Empirio-Criticism, in opposing experience to the transcendent; but it replaces "immanent experience" of the transcendent by "pure reason," prior. It opposes "pure experience" to "pure reason," while it agrees with Kant's limitation of knowledge to experience. Avenarius held a view of knowledge very like that of Mach's view of the mind as thinking. One of the fundamental postulates of philosophy, as we have seen, is the "critical" or "transcendent" view of the mind, as "demythologized" or "unmythologized," as the "Kritik der reinen Erfahrung" (1876), he based his views on the principle of least action, contending that, as in Nature there is a minimum or maximum production of the least or greatest effect, in those determinations of a general belief tends in the easiest direction. In illustration of this tendency, he pointed out that mind tends to assimilate a new impression to a posteriori form; and generalization to bring as many impressions under as few general concepts as possible, as far as it generalizes from pure experience of the given. Now is there any objection to this economical view of thought, as long as we admit that Avenarius with difference and causality, the least action thought is the least action neither more nor less than necessary to the point, which is the reality of things. Afterwards, in his Kritik der reinen Erfahrung (1888-1890), Avenarius aimed at giving a description of pure experience which he identified with the nature view of the world held by all unprejudiced persons. What, then, is this pure experience? "Every human individual," says he,
“originally accepts over against him an environment with manifold parts, other individuals making manifold statements, and what is stated in some way as being an environment.”

This definition, under the environment are what he means by pure experience. At first this starting-point looks like dualistic realism, but in reality the author only meant dualism within experience. He takes “ego” to be a part of “ego” and “world” into which we are inserted. He freely assumes that all there exists of man is a counterpart (Gegenbild) of ourselves as central part (Centralbild)

“We cannot,” he adds, “think ourselves as central part away.

He went so far as to assert that, in the experience of all human beings in the world, all one means is that there was besides oneself no other central part to whom one’s counterparts might also be counterparts. The consequence is that all the world as well as our own E and C are concretely dependent on one another. This division of values brings us to the second point of his philosophy, his theory of how he put the so-called “vital series,” by which he assayed to explain all life, action and thought. A vital series he supposed to begin with something C against the maintenance by C, and then the recovery by C of its maintenance-value, in accordance with the principle of least action. Further series that are dependent on the first vital series of C is sometimes of this simple kind, at other times it is complicated by the addition of a dependent vital series in E, by which, in his fondness for too general and far-reaching solutions, he explains conscious action and thought. (Thus, if a pain is an E-value directly on a disturbance in C, and a pleasure another E-value directly dependent on a recovery of C, it will follow that a transition from pain to pleasure is a postulate of the essential concretion of environment, Avemarius held that this empirical-critical supposition, which according to him is also the natural view of pure experiences, contains no opposition of physical and psychical, of an outer physical and an inner psychical world—an opposition which seemed to him to be a division of the inseparable. He considered that the whole hypothesis that an outer physical things cause a change in one’s central nervous system, which again causes another change in the psychic system of the body, is a radical error of psychical theory. He held that E and C are concretely dependent on one another, and that the natural view of the universe, and is due to what he called “introduction,” or the hypothesis which encloses soul and its faculties in the body, and, being created by a microcosmic antithesis and a macrocosmic one are the only way to explain how an outer physical stimulus can impart something into an inner psychic soul. He concluded therefore, having disposed of this fallacy of introduction, he returned to the natural view and the empirical co-ordination of ego and environment, as central part and counterpart, in E-values, C-values and E-values.

It is curious that Avemarius should have brought forward this artificial hypothesis as the natural view of the world, without reflecting that on the one hand the majority of mankind believes that the environment (R exists), has existed, and will exist, without being a counterpart of any living being as central part (C); and that on the other hand it is so far from being natural to man to believe that sensation and thought (E) are different from, and merely dependent on, his body (C), that throughout the Homeric poems, though soul and body are very often the same, as a rule, mind is regarded as a purely bodily organism. It is indeed difficult to assign any rational place to the empirico-criticism of Avemarius. It is materialistics without being materialistic; it is realistic without being realistic. One of the most universal of all assumptions of all psychological systems is that psychological makes it almost too indefinite to classify among philosophical systems. But its main point is the essential co-ordination of ego and environment, as central part and counterpart, in experience.

It is therefore nearly connected with “immanent philosophy,” Schuppe, indeed, wrote an article in the "Vierteljahrschrift" of Avemarius to prove their essential agreement. At the same time Schopenhauer, one could not understand the uselessness and insignificance of the article by a priori categories could hardly be accepted by Avemarius as pure experience, or as a natural view of the world.

4 Voluntaristic Phenomenology of Wundt. — Wundt’s metaphysics will form an appropriate conclusion of this sketch of German idealism, because his patient industry and eclectic spirit have fitted him to assimilate many of the views of his predecessors. Wundt proves that all idealisms are in a way one. He starts as a phenomenalist, from which knowledge is experience containing subject and object in inseparable relation, and he reduces the correlative of von Kant’s ‘ideal’ to a scientific philosophy comprehending the universe in the simplest possible manner. Again he agrees with the reaction both to Hume and to Kant in limiting knowledge to mental phenomena, and has affinities with Mach as well as with Lange. His main sympathies are with the Neo-Kantians, and especially with Lange in modifying the a priori, and in extending the power of reason beyond phenomena to an ideal world; and yet the cry of his phenomenalism is not “back to Kant,” but “beyond Kant,” and the same in many details he is with noumenalists; with Fechner in psychophysics, in psychophysical parallelism, in the independence of the physical and the psychical chains of causality, in reducing physical and psychical to a difference of aspects, in substituting impulse for accident in organic evolution, and in wishing to recognize a gradation of individual spiritual beings; with Schopenhauer and Hartmann in voluntarism; and even with Schelling and Hegel in their endeavour, albeit on an artificial method, to bring experience under notions, and to unite subject and object in one concrete reality. He has, with a practical relation to realism, built his whole philosophy on four psychological positions: his phenomenalist theory of unitary experience, his voluntarism, his actualistic theory of soul, and his psychological theory of parallelism. They are positions also which deeply affect, not only the psychological, but also the metaphysical idealisms of our time, in Germany, and in the whole civilized world.

i. His first position is his phenomenalistic theory of unitary experience. According to him, we begin with an experience of ideas, in which object and idea are originally identical. This is a complete division of subjective and objective factors; and especially in natural science we so far abstract the objects as to believe them at last to be independent things: but it is the office of psychology to warn us against this popular dualism, and to teach us that there is only a duality of psychical and physical, which are divisible, not separable, factors of one and the same content of our immediate experience; and experience is our whole knowledge of metaphysical deduction from this psychological view is that all we know is mental phenomena, “the whole outer world exists for us only in our ideas,” and all that our reason can logically do beyond these phenomena is to frame transcendental idealism.

ii. His second position is his voluntarism. He agrees with Schopenhauer that will is the fundamental form of the spiritual. He does not mean that he is going to pretend that we derive our idea of will from sensation, and feeling, and in feeling, and as will. Moreover, he contends that we can neither have idea without will, nor will without idea and feeling; that idea alone wants activity; that will alone wants content; that will is identifying and activity (vorstellende Tätigkeit), which always includes motives.
and ends and consequently ideas. He is therefore a Scholastic, and like his younger contemporary Paulsen, in calling will funda-
mental he includes impulse (Triebe). Accordingly he divides will into two species: on the one hand, simple volition, or impulse, which in itself has no active consciousness attached, but in which an end is arrived at, and therefore an idea, e.g. the impulse of a beast arising from hunger and sight of prey; on the other hand, complex volition issuing in a volition of ends (Zweck-Denken) is a volition of ends, the adop-
tion of a motive, with or without choice. Like other German voluntarists, he impugns "impulsive will" to the whole organic world. He follows Fechner closely in his answer to Darwin. If he supposes the will to be a bottomless cauldron, then impulses becoming habits produce structural changes, which are transmitted by heredity; and as an impulse thus gradually becomes secondarily active, so in the first instance it is active in itself, in their turn become secondarily automatic, and so on. As now he supposes feeling even in "impulsive will" to be directed to an end, he deduces the conclusion that in organic evolution the pursuit of final ends precedes and is the origin of mechanism. But at what a cost! He has endowed all the plants in the world with motives, feelings directed to an end, and ideas, all of which, according to him, are required for impulse! He apparently forgets that mere feelings often produce actions, as when one writes with pain. But even so, have plants even those lowest impulses from feelings of pain or pleasure? Wundt, however, having gone so far, treats the problem without his colleague. Wundt and Fechner in endowing the material universe with will or any other mental operation, because his phenomenalism already reduces inorganic nature to mere objects of experiencing subjects. Wundt also, because he does not suppose a new kind of principle which was anticipated by the paradox of Descartes: that will is required to give assent to anything perceived (Principia philosophiae, i. 34). Wundt supposes not only that all organisms have outer will, the will to act, but that also inner will—the will to think. Now there is a will to think, and Aristotle pointed out that thinking is in our power whenever one pleases, whereas sense depends on extension and duration (Metaphysics, 9. 8). So also, Wundt supposes that all willing is thinking. What is the source of this paradox? It is a confusion of impulse with will, and activity with both. He supposes that all agency, and therefore the agency of thinking, is in the same way an actualistic construction of all knowledge, requiring will directed to the end of duty. Wundt, in consequence, thinking with Kant that "appreciation is a spontaneous activity, and with Fichte that the act of the will is merely the act of the consciousness, he supposes that thinking is in all organisms, and therefore inner will. Further, on his own account, he identifies appreciation with the process of attention, and regards it as a spontaneous activity. In accordance with his general position, he identifies to all association of ideas, to all imagination and understanding. According to him, then, attention, even involuntary attention, requires inner will; and all the functions imparted by Hume to association, as well as those imparted to understanding by Kant, require appreciation, and therefore inner will. At the same time he does not suppose that they all require the same kind of will. In accordance with his previous division of outer will into impulsive and decisive, he restricts the will as the collection of passive appreciation and active appreciation. Apperception in general thus becomes activity of inner will, constituting the process of attention, and outer will as the impulsive will, requiring in Wundt, and active in the form of decisive will required for understanding and judgment. Now, beneath these confusing phrases the point to be regarded is that, in Wundt's opinion, though we can receive sensation from the outer world, we can apprehend nothing at all from the inner world. This exaggeration of the real fact of the will to think ignores throughout the position of little man in the great world and at the mercy of things which drive him perforce to sense and from sense to feeling and active consciousness, and at the same time to im- press upon us that without an inner will and consciousness, we have no interest in something else of no importance. "The Dean is dead (Pray, what is Trumps?)? Yet many psychologists accept the universality of this will to believe, and among them James, who is so near to Wundt's researches in pure psychology, it is built up of practical interests. We should rather say "far too much." Wundt, however, goes still farther. According to him, that which acts in all organisms, that which acts in all thinking, that which divides unitary experience into subject and object, the source of self-consciousness, the unity of our mental life, "the most decisive of our ideas," 241 is a will. And thus, to his whole voluntarism means, that while the inorganic world is mere object, all organization is conveyed will, and all thinking is apperceptive. But it must be remembered that these conceptions of the will are based on the assumption of some sort of volun-
tarity, impulse, and rational desire, all under the one word "will," as well as by omitting the involuntary activity of intelligence under the name of voluntary. And so it is that much of Wundt's volun-
tarism is a substitute for direct assertion of the whole universal voluntarism of Schopenhauer and Hartmann, but believes in individual wills, and a gradation of wills, in the universal. And so actually, he supposes our personal individual will is a collective will of simpler voluntary units, and it thinks that this conclusion is proved by the continuance of actions in animals after parts of the brain have been removed. In a similar way he supposes our wills are included in the collective will of society. He does not, however, think with Schuppe that there is one common consciousness, but only that there is a collective consciousness and a collective will; not perceiving that then the sun—in his view a mere object in the experience of every member of the collection—would be only a collective sun. Lastly, he believes that reason forms the "ideal" of God as world-
will, a will that exists without grammatical subject. On the whole, his volun-
tarism, though like that of Schopenhauer and Hartmann, is not the same; not Schopenhauer's, because the ideating will of Wundt's philosophy is not a universal irrational will; and not Hartmann's, because his views of the realm of the irrational, of phenomenalism, is supposed to extend through the world of organisms, the whole inorganic world remains a mere object of unitary experience.

In his third position is his actualistic theory of soul, which he shares with Fichte, Hegel, Fechner and Paulsen. When Fichte had rejected the Kantian soul in itself and developed the Kantian active will in a connoted view, Wundt had a more considered view, and so he puts forward an actualistic view of con-
structive activity. Fechner added that the soul is the whole spiritual process manifested in the whole unitary bodily process without being a substance. Wundt accepts Fichte's theory of the actuality, and Fechner's concept of the organic soul. Taking substance entirely in the sense of substrate, he argues that there is no evidence of a substantial substrate beneath mental operations; that there is nothing except unitary experience constituting the soul. Ideas, he says, are not in the soul, but that soul in short is not substantia, but actus. He does not see that this unity is only apparent, for men think not always, and will not always. Nor does he see that a man is conscious not of idea, feeling, will, experience, but of something conceiving, feeling, willing and experiencing, which he gradually learns to call himself, and that he is never conscious of doing all this "mining" without his their, without their giving the will, which is sometimes a cause of a psychic process, nor vice versa. Precisely like Fechner, he holds that there is a physical causality and energy and there is a psychic causality and energy, parallels which never meet, but approximate. This view he opposes to his own phenomenalism, that his body is only an object abstracted from his unitary experience, which is all that really is of him.

iv. Henceforth his fourth point is his psychological theory of parallelism of physical and psychical reduced to identity in unitary experi-
ence. Here his philosophy is Fechnerian phenomenlized. He accepts Fechner's extension of Weber's law of the external stimuli of psychical parallelism remarking that the "physiological inter-
pretation is entirely hypothetical." He accepts physiological parallelism in the sense that every psychical process has a physical accompaniment, every physiological function has a psychical parallelism, that parallelism is cause of a psychical process, nor vice versa. Precisely like Fechner, he holds that there is a physical causality and energy and there is a psychic causality and energy, parallels which never meet, but approximate. This view he opposes to his own phenomenalism, that his body is only an object abstracted from his unitary experience, which is all that really is of him.

PHENOMENAL IDEALISM

METAPHYSICS
my body, is merely an object abstracted from an idea of my experience; and what is really known is only what is actually seen, not separable, into body and soul, physical and psychical factors of one and the same unitary experience. Wundt is confined by his starting-point to his deduction that what we can only call the phenomena, ideas regarded as objects and subjects of experience.

With these four positions in hand, Wundt’s philosophy consecutively follows, beginning with his psychology. He begins by the most natural approach, that of the sensations, but he insists that these always exist in a psychical compound, from which they can be discovered only by analysis and abstraction; and his paradox that the sensations, being abstract ideas, are not sensations at all, but objects and subjects of an essential and more fundamental kind. Further, Wundt declares that the psychical compound of sensations, with which, according to him, we actually start, is not a complex sensation, but a compound idea; so that I expect to believe the statements of D, F, A, and have only a compound idea of the chord—as if the hearing of music were merely a series of ideas! Wundt, however, has a strong objection against substituting compound idea for sensation and accepts Lotze’s hypothesis of local signs, and adds a hypothesis of temporal signs. He supposes that we have no sensations of space and time, as the nativists suppose, but that, while local signs give us spatial ideas, feelings of expectation are temporal signs giving us temporal ideas, and that these ideas enter into the psychical compound, which is our actual starting-point. It follows that every psychical compound into which we start, and which contains at most one idea, and, as time at any rate accompanies all our sensations, it follows that every psychical compound of sensations, containing as it does, always temporal, if not also spatial, ideas, must be a compound idea, and, as time and space are complex, only a compound idea, a compound sensation, a compound idea, a compound sensation. The next question is, how complicated? Wundt’s answer is that inner impulsive will, in the form of passive apperception, forms compound ideas by association; so that all our psychical phenomena, that is, our psychical phenomena, the ordinary associations of the ordinary sensations of our own sensations, and to the ordinary associations, which descend from Hume, an association which he calls fusion (Verschmelzung), and supposes that it is a fundamental process of fusing sensations with spatial and temporal ideas into a compound idea. But he also recognizes association by similarity, or assimilation, or “apperception” in Herbart’s more confined sense of the word, and association by contiguity, or correlation. Recognizing, then, three kinds of association in all, he supposes that they are the first processes, by which inner will, in the form of passive apperception, generates ideas from sense. So he supposes, as a further development of Hume’s. But he does not agree with Hume that mind is nothing but sensations, ideas, and associations, but with Kant, that there are higher combinations. According to him, inner decisive will, rising to active apperception, proceeds to what he calls “apperceptive combinations” (Apperceptionsvorstellungen); first to simple combinations of relating and comparing, and then to complex combinations of synthesis and analysis in imagination and understanding; in complex combinations of aggregates of ideas (Gesammtvorstellungen), and then at last analysis, by dividing an aggregate idea into subject and predicate, forms a judgment (see further Logic). The meaning of this is that an idea is true, when it is not ever confused to a jumble of ideas. Wundt, indeed, is aware of the consequences. If judgment is an analysis of an aggregate idea into subject and predicate, follows, as he says, “as judgment, logic, so is the most logical method of the study of the members of any aggregate of ideas to one another” (System der Philosophie, 66, 1st ed.). He cannot allow any inference of things beyound for substantiating compound idea for sensation.

In his logic, and especially in his epistemology, Wundt appears as a mediator between Hume and Kant, but with more leaning to the latter. While he regards association as lying at the basis of all knowledge, he does not think it sufficient. He accepts Kant’s transcendentalism, as he regards it, that is, the transcendental idealism. Wundt makes a reservation to his own transcendentalism. Between Hume’s and Kant’s a priori hypothesis he proposes a logical theory of the order of notions beyond experience. He explains that the arrangement of facts requires “general supplementary notions (Hilfsbegriffe), which are not contained in experience itself, but are gained by a process of logical treatment of this experience.” Of these supplementary notions, he holds that they are not, as Kant supposed, a logical causality, coming from the necessity of thought that all our experiences shall be arranged according to ground and consequent. That seems most logical, an abstract, or concept, or proposition of appearance, as Hume said and Kant allowed, is also Wundt’s provision of a point. How then do we arrive at causality? Not, says Wundt, by association, as Hume said, but by thinking: not, however, by a purely intellectual process, but by projecting, he thinks, the logical principle of ground and consequent (which Leibnitz had called the principle of sufficient reason) as a causal law to empirical appearances. Now, Wundt is aware that this is not always possible, for he holds that the logical principle of ground belongs generally to the connexion of thoughts, the causal law to the combination of empirical appearances. Nevertheless he believes that, with regard to a logical principle of ground and consequent, we can apply the logical principle as causal law to this combination, and say that one appearance is the cause of another, thus adding a notion of causality not contained in the ideality of associations.

He quotes as an instance that Newton in this way added to the planetary appearances contained in Kepler’s laws the gravitation principle. He says, in effect, that we can add the notion of cause from any logical ground beyond experience, any more than he did the third law of motion. Wundt does not realize that, though we can often use a logical (principium cognoscendi) as a causality principle (principium causae) for deductive effects, we can do so only when we have previously inferred from experience that such a cause does produce that kind of effect (see Logic). Otherwise, logical ground remains logical ground, as in any non-physical, such as the familiar one from “All men are mortal,” which causes me to know that I shall die, without telling me the cause of death. Wundt, however, having satisfied himself of the power of mere logical thought beyond experience, goes on to further apply his hypothesis, and supposes that, in dealing with the physical world, logical thinking having added to experience the “supplementary notion” of a causal law, which vary together, adds also the “supplementary notion” of substance as substratum of the connected appearances. But, using substance as he does always in the Kantian sense of permanent individuality, and again in the Humean sense of separate enduring appearances, and adding this Kantian sense of any distinct thing, he proceeds to make distinctions between the applications of causality and of substance. Even in the physical, he confines substance to matter, or what Aristotle calls “material substantia,” the aggregate of our compound phenomena, passive, and limits substantial causality to potential energy, while he supposes that actual causality is a relation not of substances but of events. On this false abstraction Sigwart has made an excellent criticism in an appendix at the end of his Logic, where he remarks that we cannot isolate events from the substances of which they are attributes. Motions do not cause motions; one body moving causes another body to move: what we call causation is really substance. Secondly, when Wundt comes to the psychical, he naturally infers from his narrow Kantian definition of substance that there is no proof of a “spiritual.” Wundt has, however, made another mistake, not in the logical, or mental operations, and falsly thinks that he has proved that there is no substance mentally operating in the Aristotelian sense. Thirdly, on the grounds that logical thinking adds the notion of substance, as substrata, to experience of the physical, but not of the psychical, and that the most proper being of mind is will, he concludes that wills are not active substances, but substance-generating activities (“richtige Substanzen sondern substanzerzeugende Thätigkeit,” System, 429).

What kind of metaphysics, then, follows from this compound of psychology and epistemology? As with Kant against Hume, so with Wundt against Mach and Avenarius, the world we know will contain something more than mere complexes of entities, and more than the bare experience: with Wundt it will be a world of real causes and some substantiae, constituted only by experience and partly by logical thinking, or active inner will. But as with Kant, so with Wundt, this world will be only the richer, not the wider, for these notions of understanding; because they are only contributed to the original experience, and, being mentally contributed, only the more surely confine knowledge to experience of mental phenomena. Hence, according to Wundt, the world we know is still unitary experience, distinguished, not separated, into subject and object, aggregates of ideas analysed by judgment and combined by inference, an object of idea elaborated into causes and substances by logical thinking, at most a world of our ideas composed out of our sensations, and arranged under our categories of our understanding by our inner wills, or a world of our ideating wills; but nothing else. It is Wundt’s own statement of his solution of the epistemological problem “that on the one hand the whole outer world exists for us only in our ideas, and that on the other hand a consciousness without objects of idea is an empty abstraction which possesses no actuality” (System, 212–213). There remains his theory of reason. His pupil, Oswald Külpe (1862–1936), in a monograph on the basis of unitary experience, says in his Einleitung in die Philosophie (1895; 4th ed. 1907) that Wundt in his System derives the right of metaphysics to transcend experience from similar procedure
within the limits of the special sciences. This is Wundt's view, but only in the sense that reason passes from idealism to "ideas," whether in the special sciences or in metaphysics. Reason, as in most modern psychologies and idealisms, is introduced by Wundt, after all sorts of operations, too late; and, when at length introduced, it is described as going beyond ideas and notions to "ideas" (Ideen), as an ideal continuation of series of thoughts beyond given experience—nothing more. Reason, according to Wundt, is like pure reason according to Kant; except that Wundt, receiving Kantism through Neo-Kantism, thinks that reason arrives at ideals not a priori, but by way of preceding operations, and consciousness has abolished the thing in itself, will not follow Kant in his inconsistent passage from pure to practical reason in order to postulate a reality corresponding to "ideas" beyond experience. Wundt, in fact, agrees with Lange: that reason transcends experience of phenomena only to conceive "ideas." This being so, he finds in mathematics two kinds of transcendence—real, where the transcendent, though not actual in experience, can become partly so, e.g., the divisibility of magnitudes; imaginary, where it cannot, e.g., n-dimensions. He supposes in metaphysics "all contains the impenetrable truth of the Kantian psychology, and ontological "ideals." He supposes real as well as imaginary transcendence in cosmological "ideas;" the former as to the forms of space and time, the latter as to content, e.g., atoms. But he limits psychological and ontological "ideals" entirely to imaginary transcendence. The result is that he confines metaphysical transcendence to "a process into the imaginary" as regards the substantial and causal content of cosmological "ideals," and altogether as regards psychological and ontological "ideals." Thus, according to him, in the first place reason forms a cosmological "ideal" of a multitude of simple units related; secondly, it forms a psychological "ideal" of a multitude of wills, or substance-generating activities, which communicate with one another by ideas so that wills ideas in will, while together they constitute a collective will, and it goes on to form the moral ideal of humanity (das sittliche Menschheitsideal); and, thirdly, it forms an ontological "ideal" of God as ground of this moral "ideal," and thence of all being as means to this end, and an "ideal" of God as world-will, of which the world is development, and in which individual wills participate each in its sphere. Herein, says Wundt, lies Kant's transcendental idealism, and the proposition that the moral order of the world is the single real proof of the existence of God (System, 405; cf. 439). "Only," he adds, "the expression proof is here not admissible. Rational 'ideals' are in general not provable." As the same limit is applied by him to all transcendent rational "ideals," and especially to those which refer to the content of the notion of the world, and, like all psychological and ontological "ideals," belong to the imaginary transcendence, his conclusion is that reason, in transcending experience, logically conceives "ideals," but never logically infers corresponding realities.

The conclusion that reason in transcending experience can show a necessity of these "ideals" is the only conclusion which could follow from Wundt's phenomenalism in psychology, logic, and epistemology. If knowledge is experience of ideas distinguished by inner will of apprehension into subject and object in inseparable connexion, if the starting-point is ideas, if judgment is analysis of an aggregate idea, if inference is a mediate reference of the members of an aggregate of ideas to one another, then, as Wundt says, all we can know, and all reason can logically infer from such data, is in our ideas, and consciousness without an object of idea is an abstraction; so that reason, in transcending experience, can show the necessity of ideas and "ideals," but infer no corresponding reality beyond, whether in nature, or in Man, or in God. Wundt, starting from a psychology of unitary experience, deduces a consistent metaphysics of no inference of things transcending experience through-out—or rather until he came to the very last sentence of his System der Philosophie (1889), where he suddenly passes from a necessity of "ideals" (Ideen), to a necessity of "faith" (Glauben), without "knowledge" (Wissen). He forgets apparently that faith is a belief in things beyond ideas and ideals, which is impossible in his psychology of judgment and logic of inference. The fact is that his System may easily seem to prove more than it does. He describes it as idealism in the form of ideal realism, because it recognizes an ideating will requiring substance as substratum or matter for outer relations of phenomena. But when we look for the evidence of any such will beyond ourselves and our experience, we find Wundt offering nothing but an ontological "ideal" of reason, and a moral "ideal" requiring a religious "ideal," but without any power of inferring a corresponding reality. The System then ends with the necessity of "ideals" of a transcending world-will, which provides no ground for the necessity of any belief whatever in the being of God, or indeed in any being at all beyond our own unitary experience.

Wundt, however, afterwards wrote an Einleitung in die Philosophie (1905; 4th ed. 1906), in which he speaks of realism in the form of ideal realism as the philosophy of the future. It is not to be idealism which resolves everything into spirit, but realism which gives the spiritual and the material each to own place in harmony with scientific consciousness. It is not to be dualistic but monistic realism, because matter is not separate from spirit. It is not to be materialistic but ideal realism, because the physical and the psychical are inseparable parallels inexplicable by one another. It is to be monistic ideal realism, like that of Fichte and Hegel; not, however, like theirs idealistic in method, a Phantastisches Begriffgebäude, but realistic in method, a Wissenschaftliche Philosophie. It is to be ideal realism, as in the System. It is not to be a species of idealism, as in the System—but of realism. How are we to understand this change of front? We can only explain it by supposing that Wundt wishes to believe that, beyond the "ideal," there really is proof of a transcendent, ideating, substance-generating will of God; and that he is approaching the noumenal voluntarism of his younger contemporary Paulsen. But to make such a conversion from phenomenalism plausible, it is necessary to be silent about his whole psychology, logic, and epistemology, and the consequent limitation of knowledge to experience, and of reason to ideas and "ideals," without any power of inferring corresponding things.

What a pity it is that Wundt had committed himself by his psychology to phenomenalism, to unitary experience, and to the limitation of judgment and reason to ideas and ideals! For his phenomenalism prevents him from consistently saying the truth inferred by reason—that there is a world beyond experience, a world of Nature, and a will of God, real as well as ideal. To understand Wundt is to discover what a mess modern psychology has made to metaphysics. To understand phenomenal idealism in Germany is to discover what a narrow world is to be known from the transcendental idealism of Kant shorn of Kant's inconsistencies. To understand noumenal idealism in Germany and the rise of metaphysical idealism in modern times is to discover that psychological is the origin of all metaphysical idealism. If we perceive only what is mental, all that we know is only mental. But who has proved that psychological starting-point? Who has proved that, when I scent an odour in my nostrils, I apprehend not odour but a sensation of odour; and so for the other senses? Sensation, as Aristotle said, is not of itself: it is the apprehension of a sensible object in the organism: I perceive pressure, heat, colour, sound, flavour, odour, in my five senses. Having felt reciprocal pressures in touch, I infer similar pressures between myself and the external world.

6.—ENGLISH IDEALISM

1. The Followers of Hume's Phenomenalism.—Compared with the great systems of the Germans, English idealism in the 19th century shows but little originality. It has been largely borrowed either from previous English or from later German idealism, and what originality it has possessed has been mainly shown in that spirit of eclectic compromise which is so dear to the English mind. The predominant influence, on the whole,
has been the phenomenon of Hume, with its slender store of sensations, ideas and associations, and its conclusion that all we know is sensations without any known thinkers or any other known things. This phenomenalism was developed by James Mill (1773-1836) and J. S. Mill (1806-1873), and has since been continued by A. Bain. It also became the basis of the philosophies of Huxley and of Spencer on their phenomenalistic side. It is true that Spencer's "transfigured realism" contains much that was not dreamt of by Hume. Spencer widens the empirical theory of the origin of knowledge by his brilliant hypothesis of inherited organized tendencies, which has influenced all later psychology and epistemology, and tends to a kind of compromise between Hume and Kant. He describes his belief in an unknowable absolute as "carrying a step farther the doctrine put into shape by Hamilton and Mansel." He develops this belief in an absolute in connexion with his own theory of evolution into something different both from the idealism of Hume and the realism of Hamilton, and rather falling under the head of materialism. Nevertheless, as he believes all the time that everything knowable throughout the whole world of evolution is phenomena in the sense of subjective affections of consciousness, and as he applies Hume's distinction of impressions and ideas as a distinction of vivid and faint states of consciousness to the distinction of empirical and spiritual, inner and outer phenomena, his philosophy of the world as knowable remains within the limits of phenomenalism. Nothing could be more like Hume than his final statement that what we are conscious of is subjective affections produced by objective agencies unknown and unknowable. The "anti-realism," which takes the lion's share in "transfigured realism," is simply a development of the phenomenalism of Hume. Hume was also at the bottom of the philosophies of G. H. Lewes, who held that there is nothing but feelings, and of F. H. Clifford. Nor is Hume yet dethroned, as we see from the works of Karl Pearson and of William James, who, though an American, has exercised a considerable influence on English thought. The most flourishing time of phenomenalism, however, was during the lifetime of J. S. Mill. It was counteracted to some extent by the study at the universities of the deductive logic of Aristotle and the inductive logic of Bacon, by parts of Mill's own logic, and by the natural realism of Reid, Stewart, and Hamilton, which met Hume's scepticism by ascerting a direct perception of the external world. But natural realism, as finally interpreted by Hamilton, was too dogmatic, too unsystematic, and too confused with elements derived from Kantian idealism to withstand the brilliant criticism of Mill's "Examination of Sir William Hamilton's Philosophy" (1862), a work which for a time almost persuaded us that Nature as we know it from sensations is nothing but permanent possibilities of sensation, and oneself only a series of states of consciousness.

2. The Influence of Kant and Hegel.—Nevertheless, there have never been wanting more soaring spirits who, shocked at the narrowness of the popular phenomenalism of Hume, have tried to find a wider idealism. They have, as a rule, sought it in Germany. Before the beginning of the 19th century, Kant had made his way to England in a translation of some of his works, and in an account of the "Elements of the Critical Philosophy" by A. F. W. Willich, both published in 1798. After a period of struggle, the influence of Kant gradually extended, and, as we see in the writings of Coleridge and Carlyle, of Hamilton and Mansel, of Green and Caird, of Laurie, Martinou and others, the authors of the English thought almost equal to that of Hume (see Impressionism). Both the appeal to the English love of experience, and Kant had these advantages over Hume: that within the narrow circle of sensible phenomena his theory of understanding gave to experience a fuller content, and that beyond phenomena, however inconsistently, his theory of reason postulated the reality of God, freedom and immortality. Other and wider German philosophies gradually followed that of Kant to England. Coleridge (1772-1834) not only called attention to Kant's distinction between understanding and reason, but also introduced his countrymen to the noumenal idealism of Schelling, in his "Biographia Literaria" (1817). He says that Schelling's "Naturephilosophie und System des transcendenten Idealismus" he first found a general coincidence with much that he had toiled out for himself, and he repeated some of the main tenets of Schelling. Carlyle (1795-1881) laid more emphasis on Fichte. At the height of his career, when between 1840 and 1845 many of Fichte's works were being translated in the Catholic Series, he called attention to Fichte's later view that all earthly things are but as a venturesome appearance under which the Divine idea of the world is the reality. Extravagant as this noumenalism is, it was perhaps the only philosophy which was possible in Germany. Among other followers of German idealism were J. F. Ferrier (q.v.), who adopted the hypothesis of Schelling and Hegel that there is one absolute intelligence (see his "Lectures and Philosophical Remains," 1866, i. 1-33; ii. 545-568), and J. Hutchinson Stirling (q.v.). About the same time Benjamin Jowett (q.v.) had been studying the philosophy of Hegel; but, being a man endowed with much love of truth but with little belief in first principles, he was too wise to take for a principle Hegel's assumption that different things are the same. He had, however, an immense influence in the universities of Cambridge and Oxford. Green and E. Caird (q.v.). Both proceeded to take Hegelianism seriously, and between them spread a kind of Hegelian orthodoxy in metaphysics and in theology throughout Great Britain. Green ("Prolegomena to Ethics," 1853) T. H. Green, tried to effect a harmony of Kant and Hegel by proceeding from the epistemology of the former to the metaphysics of the latter. Taken for granted the Kantian hypothesis of a sense of sensations requiring synthesis by understanding, and the Kantian conclusion that Nature as known consists of phenomena united by categories as objects of experience, Green argued, in accordance with the essential nature of that knowledge, in order to unite the manifold of sensations by relations into related phenomena, requires unifying intelligence, or what Kant called synthetic unity of apperception, which cannot itself be sensation, because it arranges sensations; and he argued, in accordance with Kant's second position, that therefore Nature itself as known requires unifying intelligence to constitute the relations of its phenomena, and to make it a connected world of experience. When Green said that "Nature is the system of related appearances, and related appearances are not empirical at all..." he was speaking as a pure Kantian, who could be answered only by the Aristotelian position that Nature consists of related bodies beyond appearances, and by the realistic supposition that there is a tactical sense of related bodies, of the inter-resisting members of the organism, from which reason infers similar related bodies beyond sense. But now, whatever opinion we may have about Nature, at all events, as Green saw, it does not come into existence in the process by which this person or that begins to think. Nature is not my nature, nor your nature, but one. From this fact of unity of Nature and of everything in Nature, combined with the two previous positions accepted, namely Nature put out from Kant, Green proceeded to argue, altogether beyond Kant, that Nature, being one, and also requiring unifying intelligence, requires one intelligence, an eternal intelligence, a single spiritual principle, prior to, and the condition of, our individual knowledge. According to him, therefore, Nature is one system of phenomena united by relations as objects of experience, one system of related appearances, one system of one eternal intelligence which reproduces itself in us. The "true account" of the world in our minds is "the concrete whole, which may be described indifferently as an eternal intelligence realized in the related facts of the world, or as a system of related facts rendered possible by such an intelligence, partially and gradually reproduces itself in us, communicating piecemeal, but in inseparable correlation, understanding and the facts understood, experience and the experienced world." Nobody can mistake the Schellingian and Hegelian nature of this system. It is the Hegelian view that the world is a system of absolute reason. But it is
not a Kantian view; and it is necessary to correct two confusions of Kant and Hegel, which have been imported with Hegelianism by Green and Caird. Ferrier was aware that in Kant's system "there is no common nature in all intelligence" (Lectures, ii. 368). Green, on the other hand, in deducing his own conclusion that the world is, or is a system of, one eternal intelligence, incautiously put it forward as "what may be called broadly the Kantian view" (Prolegomena, § 36), and added that he follows Kant "in maintaining that a single active conscious principle, by whatever name it be called, is necessary to constitute such a world, as the condition under which alone phenomena, i.e. the outer objects of sense, can be apprehended" (ibid. § 38). He admitted, however, that Kant also asserted, beyond this single universe of a single principle, a world of unknowable things in themselves, which is a Kantian not a Hegelian world. But Caird endeavoured to break down even this second barrier between Kant and Hegel. According to Caird, Kant reduces the inaccessible thing in itself (which he at first speaks of as affecting our sensibility) to a noumenon which is projected by reason itself (Essays, ii. 495); and in the Transcendental Dialectic, which forms the last of the two introductions to the "critical philosophy, as an intuitive understanding "whose thought," says Caird, "is one with the existence of the objects it knows" (ibid. 412, 413). Kant, then, as interpreted by English Hegelians, already believed, before Hegel, that there is one intelligence common to all individuals, and that a noumenon is a thought of this common intelligence, "an ideal of reason"; so that Kant was trying to be a Hegelian, holding that the world has no being beyond the thoughts of one intelligence. But history repeats itself; and these same two interpretations of Kant had already been made in the lifetime of Kant by Fichte, in the two introductions to the "critical philosophy," as in the "critical philosophy, in the Philosophical Journal in 1797. Now, the curious fact is that Kant himself wrote a most indignant letter, dated 7th August 1799 (Kant's Werke, ed. Hartenstein, viii. 600-601), on purpose to repudiate all connexion with Fichte. ('Fichte 'Wissenschaftslehre,' he said, is a completely untenable system, and a metaphysics of fruitless speculations, in which he disclaimed any participation; his own Kritik he refused to regard as a prodigious article to be construed by the Fichtian or any other standpoint, declaring that it is to be understood according to the laws of his own, and he went so far as to assert that his own criticism of the critical philosophy is so satisfactory to the reason, theoretical and practical, as to be incapable of improvement, and for all future ages indispensable for the highest ends of humanity. After this letter it cannot be doubted that Kant not only differed wholly from Fichte, both about the synthetic unity of apperception and about the thing in itself, but also to be construed literally throughout. When he said that the act of consciousness "I think," is "in aliam Bewussstsein ein und dasselbe", he meant, as the whole context shows, not that it is one in all thinkers, but only that it accompanies all my other ideas and is one and the same in all my consciousness, while it is different in different thinkers. Though again in the Transcendental Dialect he spoke of pure reason conceiving "ideas" of noumena, he did not mean that a noumenon is nothing but a thought arising only through thinking, or projected by reason, but meant that pure reason can only conceive the "idea" while, over and above the "ideal" of pure reason, a noumenon is a real thing, a thing in itself, which is not indeed known, but whose existence is postulated by practical reason in the three instances of God, freedom, and immortality. Consequently, Kant's explanation of the unity of a thing is that there is always one thing in itself in us many phenomena, which as understood by us are objectively valid for all our consciousnesses. What Kant never said and what his whole philosophy prevented his saying, was that a single thing is a single thought of a single consciousness; either of men, as in Fichte's philosophy, or of God and man, as in Hegel's. The passage from Kant to Hegel attempted by Green, and the harmony of Kant and Hegel attempted by Green and Caird, are unhistorical, and have caused much confusion of thought. The success, therefore, of the works of Green and Caird must stand or fall by their Hegelianism, which has indeed secured many adherents, partly metaphysical and partly theological. Among the former we may mention W. Wallace, the translator of most of Hegel's Encyclopädie, who had previously learnt Hegelianism from Ferrier; W. H. Fairbrother, who has written a faithful account of The Philosophy of Thomas Hill Green (1860); R. L. Nettleship, D. G. Ritchie, J. H. Muirhead, J. S. Mackenzie, and J. M. E. T'Aggar, who closes his acute Studies in Hegelian Cosmology (1901) with "the possibility of finding, above all knowledge and volition, one all-embracing unity, which is not only true, but good; because all truth and all goodness are but distorted shadows of its absolute perfection—" (Das Unbegreifliche, weis der Begriff selb ist'"

There are still to be mentioned two English Hegelians, who have not confused Kant and Hegel as Green did: namely, Simon Somerville Laurie (1829-1890) and F. H. Bradley (b. 1836), fellow of Merton College, Oxford. Laurie wrote Metaphysics, nova et vetus, a Return to Dualism, which makes particular inferences about outer objects, and his attack on Green is expressed towards the end of his book, where he says: "the more recent argument for God which shows, that there is a self-distinguishing one basis to which nature as a mere process of explanation is adjoined, is simply the old argument of the necessity for a First Cause dressed up in new clothes. Not by any means an argument to be despised, in short of which the whole metaphysical and inadequate analytic knowledge of mankind. His aim is to remedy this defect by psychology, under the conviction that a true metaphysics is at bottom psychology, and a true psychology fundamentally metaphysical. As psychology is therefore the proper ground of "attitude" and reason. His theory of "attitude," by which he supposes that we become conscious of objects outside ourselves, as opposed to dualism, and is indeed so natural realism as to suggest that, like Ferrier, he starts from Hamilton to end in Hegel. As, however, he does not suppose that we have a direct perception of something resisting the organism, such as Hamilton and Hume suppose, it becomes necesssary for him to co-ordinate a consciousness of objects outside itself, e.g. a stone or a stick, a man or a moon. He carries its operation before reason still farther, supposing that "attitude" negates B, C, D, etc., putting "Fire burns wood," not the way of fire burns wood, but: that a man goes farther by reason. Then, he thinks," that "attitude" gives us consciousness of an object, but without knowledge, and knowledge begins only after this. His system is thus to bring him into contact with the German idealists: he accepts from Kant the hypothesis of the synthesis and a priori categories, and he begins from this hypothesis that will be necessary to reason, from Schelling and Hegel. The hypothesis of the synthesis of the pure consciousness by a priori categories, synthetic predicates a priori, or, as he also calls them, "dialectic presupposes." Of these the most important cause, of which his theory, in short, is that by this a priori category and a priori reason are in sequence, which interchange is stating that an effect may be caused by several alternatives, then negating all but one, next concluding that this one as necessary result cause, and finally obtaining the necessity of the causal nexus by conceiving the causal nexus into identity, e.g. instead of "Fire burns wood," putting "Fire is combustible," etc., as a consequence. Lastly, while he agrees with Kant about a priori categories, he differs about the point where he gets it. Kant and Hegel, in their hypotheses, concluded that we can know nothing beyond by their means. But Laurie, applying them to "attitudes" of objects outside, considers that, though they are "reason-born," yet make us know the objects outside themselves, that they are the farthest point of his dualism, which suggests a realistic theory of knowledge, different in process from Hamilton's, but with the same result. Not so: Laurie, like Hegelian idealists, and in joint, did, to argue that they reason true not only of things but of things; and for the same reason, that things and thoughts are the same. At first in his psychology he speaks of the "attitude
and the rational perception of an outside object. But in his metaphysics founded thereon he interprets the outside object as meaning an object outside you and me, but not self-subsistent; not outside universal reason, but only ‘Beint reason.’ He quotes with approval Schelling’s phrase, ‘Nature is visible Intelligence and Intelligence visible Nature.’ He agrees with Hegel that there are two fundamental identities, the identity of all reason, and the identity of all reason and all being. Hence he explains, what is a duality for us is only a ‘quasi-duality’ from an ordinary standpoint. But his dualism, as Hegelian dualism, is merely the distinction of subject and object within idealism. Lawrence’s metaphysics is an attempt to supply a psychological propaedeutic to Hegelian metaphysics.

Bradley’s Appearance and Reality (1893) is a more original performance. It proceeds on the opposite method of making metaphysics independent of psychology. ‘Metaphysics,’ says he, ‘has no direct interest in the origin of ideas’ (244) and ‘we have nothing to do here with the psychological origin of the perception’ (35). This metaphysical method, which we have already seen attempted by Lotze, is the true method, for we know more about things than about the beginnings of our knowledge. Bradley is right to go straight to reality, and right also to inquire for the absolute, in order to take care that his metaphysical view is comprehensive enough to be true of the world as a whole. He is unconsciously returning to the metaphysics of Aristotle in spirit; yet he differs from it toto coelo in the logic of his method. Bradley harmonizes the suggestion of Spinoza that there are two fundamental identities, reason and being, with the ordinary understanding, and (as we may add) as Aristotle understood them (though with important qualifications) are self-contradictory, and are therefore not reality but appearances. If they were really contradictory they would be non-existent. However, he illustrates their supposed contradictoriness by examples, such as one substance with many attributes, and motion from place to place in one time. But he fails to show that a substance is one and many in the same respect, and that motion requires a body to be in two places at the same moment of one time. There is no contradiction (as Aristotle in part) between a man being determined by many attributes, as rational, six-foot-high, white, and a father, and yet being one whole substance distinct from any other, including his own son; nor is there any contradiction between his body being in bed at 8:15 and at breakfast at 8:45 within the same hour. Bradley’s supposed contradictions are really mere differences. So far he reminds one of Herbart, who founded his ‘realistic’ metaphysics on similar misunderstandings; except that, while Herbart concluded that the world consists of a number of simple ‘reals,’ each with a simple quality but unknown, Bradley concludes that reality is one absolute substance which has attributes and relations which are determined in an unknown manner. If his starting-point recalls Herbart his method of arriving at the absolute recalls Spinoza. In his Table of Contents, ch. xiii., on the General Nature of Reality, he says, in true Spinozistic vein, ‘The Real is one substantially. Plurality of Reals is not possible.’ In the text he explains that, if there were a plurality of reals, they would have to be beings independent of each other, and yet, as a plurality related to each other—and this again seems to him to be a contradiction. Throughout the rest of the work he often repeats that a thing related to itself cannot be related to something distinct from it if ‘independent’ means ‘existing alone’ and unrelated the same thing could not be at once related and independent; and, taking substance as independent in that sense, Spinoza concluded that there could only be one substance. But this is not the sense in which a plurality of things would have to be independent in order to exist, or to be substances in the Aristotelian sense. ‘Independent’ (επιτέχνη), or ‘self-subsistent’ (καθαρέ) means ‘existing apart,’ i.e. existing differently: it does not mean ‘existing alone,’ solitary, unrelated. This existing apart is the infinite, or the infinite, or the infinite, in one substance, is the infinite, or the infinite, in one substance, or in one substance. It is a sense in which they can all be related to each other, as I am not you, but I am addressing you. There is no contradiction, then, though Bradley supposes one, between a thing being an individual, independent, self-subsistent substance, existing apart as a distinct thing, and being also related to other things. Accordingly, the many things of this world are not self-discreet, as Bradley says, but are distinct and relative substances, as Aristotle said. The argument, therefore, for one substance in Spinoza’s Ethics, and for one absolute, the Real, which is one substantially, in Bradley’s Appearance and Reality, breaks down, so far as it is designed to prove that there is only one substance, or only one Real. Bradley, however, having satisfied himself, like Spinoza, by an abuse of the word ‘independent,’ that ‘the finite is self-discreet,’ goes on to ask what the one Real, the absolute, is; and, as he passed from Herbert to Spinoza, so now he passes from Spinoza to Kant. Spinoza answered realistically that the one substance is both extended and thinking. Bradley answers idealistically that the one Real is personal God, and experience, because all we know is tertium.

‘This absolute,’ says he, ‘is experience, because that is really what we mean when we predicate or speak of anything.’ But in order to identify the absolute with experience he is obliged, as he before abused the words ‘contradictory’ and ‘independent,’ so now to abuse the word ‘experience.’ ‘Experience,’ says he, ‘may mean experience only direct, or indirect also. Direct experience I understand to be confined to the given simply, to the merely felt or presented. But indirect experience includes all fact that is constructed from the basis of the ‘this’ and the ‘mine.’ It is all that is taken to exist beyond the bare moment,’ (248). It is to substitute indirect experience for all inference, and to maintain that when, starting from any ‘direct experience,’ I infer the back of the moon, which is always turned away from me, I nevertheless have experience of it; nay, that it is experience. Having thus confused contradiction and difference, independence and solitariness, experience and inference, Bradley is able to deduce finally that reality is not different substances, experienced and inferred, as Aristotle thought it, but is one absolute super-personal experience, to which the so-called plurality of things, including all bodies, all souls, and even all the works of God, is presented as appearance, as ordinarily understood, self-contradictory, but, as appearing to one spiritual reality, somehow reconciled. But how?

3. Other German Influences.—Brief reference only can be made to four other English idealists who have quarried in the rich mines of German idealism: G. H. Lewes, W. K. Clifford, G. J. Romanes and Karl Pearson. Lewes (q.v.), starting from the phenomenonalism of Hume, fell under the spell of Kant and his successors, and produced a compromise between G.H.Lewes. Hume and Kant which recalls some of the later German phenomenals which have been described (see his Essay Towards a Realism, his Logical and Psychological, his The Shaping of Philosophical Thought). Hume, the author of the Kritik which saved the ‘metempirical,’ he yet sympathized so far with Hegel’s noumenalism as to accept the identification of cause and effect, though he interpreted the hypothesis phenomenally by saying that cause and effect are two aspects of the same phenomenon. But his main sympathy was with Fechner, the gist of whose ‘inner psychophysics’ he adopted, without, however, the hypothesis that what is conscious in us is conscious in the all-embracing spirit of God. His phenomenalism also compelled him to give a more modified adhesion to Reid and his successors of the Scottish School, and the work of Fechner regarded every composite body as the appearance of a spirit; so that when, for example, molecular motion of air is said to cause a sensation of sound in me, it is really a spirit appearing as air which causes the sensation in my spirit. This noumenalism would not do for Lewes, who says that air is a group of qualities, and qualities are feelings, and motion is a mode of feeling. What, then, could he make of the external stimulus? He was obliged by his phenomenalism to say that it is only one feeling causing another in me. He ingeniously suggested that the external agent is one feeling regarded objectively, and the internal effect another feeling regarded subjectively; and therefore, to quote his own words, ‘to say that it is a molecular movement which produces a sensation of sound, is equivalent to saying that a sensation of sight produces a sensation of hearing.’ Accordingly,
his final conclusion is that "existence"—the absolute—is known to us in feeling," and the external changes are symbolized as motion, because that is the mode of feeling into which all others are translated when objectively considered: objective consideration being the attitude of looking at the phenomena, whereas subjective consideration is the attitude of any other sensible response." He does not say what happens when we use vision alone and still infer that an external stimulus causes the internal sensation. But his metaphysics is an interesting example of a phenomenalist, sympathizing with noumenalists so different as Hegel and Fechner, and yet maintaining his phenomenalism. In this feature the phenomenalism of Lewes is the English parallel to the German phenomenalism of Wundt. At the same time, and under the derivative influence of Wundt, rather than the more original inspiration of Fechner, W. K. Clifford (q.v.) was working out the hypothesis of psychophysical parallelism to a conclusion different from that of Lewes, and more allied to that of Leibnitz, the prime originator of all these hypotheses. Clifford advanced the hypothesis that the supposed unconscious units of feeling, or psychical atoms, are the "mind-stuff" out of which everything physical and psychical is composed, and are also things in themselves, such as Kant supposed when he threw out the hint that after all "the Ding-an-sich might be of the same nature as mind" (see "Mind," 1876, p. 66). As a matter of fact, this "mind-stuff" of Clifford is far more like the "petites perceptions" of Leibnitz, from which it is indirectly derived. This hypothesis Clifford connected with the hypothesis of psychophysical parallelism. He maintained that the physical and the psychical are two orders which are parallel without interference; that the physical or objective order is merely phenomena, or groups of feelings, or "objects," while the psychical or subjective order is both a stream of feelings of which we are conscious in ourselves, and similar streams which we infer beyond ourselves, or, as he came to call them, "ejects"; that, if we regard the psychical as an independent universe as a whole, and the psychical and the objective as parallel streams of feelings through the whole of the organic world and beyond it to the inorganic world, as a "quasi mental fact"; that at bottom both orders, the physical phenomena and the psychical streams, are reducible to feelings; and that therefore there is no reason against supposing that they are made out of the same "mind-stuff," which is the thing-in-itself. The resemblance of this noumenal idealism to that of Fechner is unmistakable. The difference is that Clifford considers "mind-stuff" to be unconscious, and denies that there is any evidence of consciousness apart from a nervous system. He agrees with Bois-Reymond that the "Gottessubstanz" is the universe as a vast brain animated by conscious mind. He disagrees with Fechner's hypothesis of a world-soul, the highest spirit, God, who embraces all psychophysical processes. Curiously enough, his follower G. J. Romanes (q.v.) took the one step needed to bring Cliffordism completely back to Fechnerism. In his Rede Lecture on "Mind and Motion" (1885), he said that Clifford's deduction, that the universe, although entirely composed of "mind-stuff," is mindless itself, did not follow from his premises. Afterwards, when the lecture was published in "Mind and Motion and Monism" (1893), this work also contained a chapter on "The World as an Eject," in which Romanes again contended against Clifford that the world does admit of being regarded as an eject, that is, as a mind beyond one's own. At the same time, he refused to regard this "world-eject" as personal, because personality implies limitation. He concludes that the integrating principle of the whole—the Spirit, as it were, of the Universe—must be something akin to, but immeasurably superior to, the "psychism" of man. Nothing can be more curious than the way in which a school of English philosophers, which originally started from Hume, the most sceptical of phenomenalists, thus gradually passed over to Leibnitz and Fechner, the originator of panpsychistic noumenalism. The Spirit of the Universe contemplated by Romanes is identical with the World-soul contemplated by Fechner.

Karl Pearson (The Grammar of Science, 1892, 2nd enlarged ed., 1900), starting from Hume's phenomenal idealism, has developed views closely allied to Mach's universal physical phenomenology. What Hume called repeated sequence Pearson calls "routine" of perceptions, and, like his master, holds that cause is an antecedent hypothesis in a routine of perceptions; while he also acknowledges that his account of the "particular" victory of the German philosophy over Stuart Mill's definition of matter as "a permanent possibility of sensations." His views, in his chapter on the Laws of Motion, that the physicist forms a conceptional model of the universe by aid of corpuses, that these corpuses are only symbols for the component parts of perceptual bodies, and that force is a measure of motion, and not its cause, are the views of Mach. At the end of this chapter he says that the only published work from the perusal of which he received any help in working out his "theories" is Mach's Die Mechanik in ihrer Entwicklung (1883). Mach began his main work on corpuscles in 1872, and Kirchhoff in 1874. But they may very well have been developed independently in Germany and in England from their common source in Hume. Their point is to stretch Hume's phenomenalism so as to embrace all science, by contending that mechanism is not at the bottom of phenomena, but is only the conceptual shorthand by aid of which men of science can briefly describe phenomena, and that all science is description and not explanation. These are the views of Mach and Pearson, and are far removed from the latter's remonstrance. Nor can we find any difference, except the manner in which Hume takes up a position of agnosticism between Clifford's assertion of "mind-stuff" and Mach's denial of things in themselves.

James Ward (q.v.), in Naturalism and Agnosticism (1899), starts from the same phenomenalistic views of Mach and Kirchhoff about mechanics; he proceeds to the hypothesis of duality within experience, which we have traced in the phenomenalisms of Schuppe, Avenarius and Wundt, and to the hypothesis of one consciousness, which appears variously in the German idealisms, not of Kant, as Ward thinks, but of Fichte, Schelling, T. B. Masterson, and Schuppe; and therefore arrives at the noumenalistic conclusion that Nature is God's Spirit. Though this work evinces a thoroughly English love of compromise, yet it is not merely eclectic, but is animated throughout by the inspiration of his "old teacher, Lotze." Lotze, as we saw, rejected bodily mechanism, reduced known bodies to phenomena, and concluded that reality is the life of God. Ward on the whole follows this triple scheme, but modifies it by new arguments founded on later German phenomenalism.

Under the first head he attacks mechanisms precisely as Mach had done (see above): if this attack had been consistently carried out it would have carried him no further than Mach. Under the second head, according to Ward, as according to Wundt, knowledge of the external object is not reducible to the dual of objective or perceptual reality, phenomenon, in the unity of experience, and not believe, as realists do, that either subject or object is distinct from this unity: moreover, experience requires "conation," because it is to interesting objects that the subject attends; conation is required for all synthesis, associative and intellectual; thinking is doing; presentation, feeling, conation are one inseparable whole; and the unity of the subject is due to activity and not to a substrate. But, in opposition to Wundt and in common with Schuppe, he believes that experience is (1) experience of the individual, and (2) experience of the race, which is but an extension of individual experience, and is variously called, in the course of the discussion, universal, collective, conceptual, rational experience, consciousness in general, absolute consciousness, intelligence, and even, after Caird, "a perfect intelligence." He regards this universal experience as the result entirely of intersubjective intercourse, and concludes that its subject is not numerically distinct from the subject of individual experience, but is one and continuous with that of its conations dependent on the perceptions of individual experience. He infers the corollary that universal experience contains the same duality of subjective and objective factors without duality. He thinks that it is the origin of the idea of causality; and he refers to the "substance," which he attributes to the interaction of active subjects with their environment and to their intercourse with each other. He applies universal experience, as Schuppe does, to explain the relation of the subject, and its interaction with the universe. But universal experience, holding that the one sun, and the whole world of intersubjective intercourse, or the "trans-subjective world," though "independent of the individual put in place as such," is "not independent of the universal experience, but the expression of that experience" (ii. 196-197). He applies universal experience
to explain how we come, falsely in his opinion, to believe that the object of experience is an independent thing; and he uses three arguments, respectively to show that since the sun is not present to himself and Wundt. He supposes first, that we falsely conclude from the sun being independent of each to being independent of all; secondly, that the world is composed of individual substances, and falsely conclude that anything experienced in him and therefore one's own subject, while the sun remains outside; and thirdly, that by "reification" of abstractions, natural science having abstracted the object of experience, falsely brings back a subjective abstrac-
tion, the sun or the subject, is an independent thing. What, then, could we know from this "duality in experience"? He hardly has a formal theory of inference, but implies through-out his argument that experience and abstractions depend upon some intermediate fact, such as qualities or phenomena, in order to conclude with ideas, not facts. When we combine his view of Nature under the first head that which is the object of experience, the single ideas, with his view of knowledge under the second head that knowledge is experience and experience, individual or universal, is of duality of subject and object in the unity of experience, it follows that all we could know from the data would be one experience of the race, one subject consisting of individual subjects, and in Nature single objects in the unity of this universal experience; and beyond we should be able to form conceptions dependent on the perceptions of individual experience in the unity of universal experience which is all. There can be no doubt that Mach, Schuppe and Wundt drew the right phenomenological conclusions from such phenomenalistic data. Not even Schuppe refers to a Neo-Kantian ideology, on the contrary, that "from a world of spirits to a Supreme Spirit is a possible step." He had definitely confined universal experience to the one experience of the race. But perhaps Carnie's phrase a perfect integration and a perfect independence, to be joined on to Nature, that this last world of universal experience is not mere mankind, but God Himself. Under the third head, however, his guide is Lotze. The argument may be shortly put thus: an object, the Nature which is the object of experience, contains all natural science, but phenomena at but phenomena and ideas; as mass is not substance, and force is not cause; as activity is not in the physical but in the psychical world; as the laws of Nature are not facts but teleological conceptions, and Nature is teleological, as well not mechanical but kine-
matical; as the category of causality is to be referred to "conation"; as, in short, "mind is active and matter inert," what then? One subject in universal experience, one subject in the subject of experience, you would suppose, and that Nature as a whole is its one object. Not so, according to Wundt; but "God as the living unity of all" and "no longer things, but the creative acts of the one Supreme." What then, is the relation of God to the one universal experience, the experience of the race, which was under the second head the unity in duality of all knowledge? He does not say. But instead of any longer identifying the experience of the race and universal experience, he concludes his book by saying "our reason is confronted and determined by universal reason. This is his way of destroying Naturalism and Agnosticism.

4. Personal Idealism.—The various forms of idealism which have been described naturally led in England, even among idealists themselves, to a reaction against all systems which involve the denial of personality. English moral philosophy cannot long tolerate a metaphysics which by merging all minds in one would destroy personality, personal causation and moral responsibility, as James Martineau well said. A new school, therefore, arose of which the protagonist was Andrew Seth Pringle-Pattison (b. 1856; professor of logic and metaphysics at Edinburgh University from 1886) in his Scottish Philosophy (1885), and Hegelianism and Personalism (1887).

"In one sense," he says, in another passage, "the real self is one and indivisible, and is unique in each individual. This is the unequivocal testimony of consciousness." What makes his vindication of conscious personality all the more interesting, is that he begins in such a context with the Hegelianism being as he does with Hegel that self-consciousness is the highest fact, the ultimate category of thought through which alone the universe is comprehended, and yet he introduces "action" as the great fact of existence. He agrees also that there is no object without a self, difficult to see exactly where he begins to differ from Hegel; but at any rate he believes in different self-conscious persons; he does not agree with the Hegelian method. He believes in both, the personal experience of one's own self-consciousness; and, though he is not very clear on the subject, he would have to admit that a thing, such as the sun, is a different object in each person's conscious experience. He has a systematic method, much as by the eclectic notion of reconciling all philosophies. F. C. S. Schiller (b. 1864, fellow of Corpus Christi College, Oxford), in Riddles of the Sphinx (1891), is a more systematic thinker. He rejects the difference between matter and spirit. He agrees with Leibnitz in the analysis of the material into the immaterial, but with Lotze in holding that the many immaterial elements coexist and interact. At the same time he differs from Lotze's conclusion that the various mental states are not parts, but merely "states of the substance is activity; differing from both Leibnitz and Lotze herein, and still more in not allowing the existence of the many beings, which is absolutely necessary. Lotze's position is a view that the world is a plurality of many coexisting and inter-
acting centres of experience, while will is the most fundamental form of experience. In connexion with these views reference should be made to a number of the essays of the editor. W. G. T. Ladd (g.s.) also believes in a "larger all-inclusive self," and goes so far as the paradox that perfect personality is only reconcilable with one infinite being. While Royce is Hegelian, Ladd presents "in a new form" Schiller, that the universal of the experience, on the other hand, in his psychological works shows that the tendency of recent psychology is to personality, interpreted ideal-
istically, so as to ascribe to personality the" the ideal self, that is, and personality means. By a curious coincidence, however, comes at the time of the appearance of the Essays on Personal Idealism, an American writer, G. H. Howison, published The Limits of Evolution, and Other Essays Illustrating the Metaphysical Theory of Personal Idealism (1901). In fact there has been an increase of philosophical intercourse between English and American universities, which is a hopeful sign of progress.

The advent of personal idealism is a welcome protest against the conclusion of Green and man in one mind, and against the conclusion of one man's mind with another's. The school undoubtedly tends towards realism. I am conscious only of myself as a person, and of my bodily signs. I know the existence of other human persons and minds only through their giving similar bodily signs. If the personal idealist consistently denies other bodies, then the bodily signs become, according to him, only part of his experience, which can prove only the existence of himself. To infer another mind he must infer another body, and the bodily environment including his and other bodies. Again, in being conscious of myself, I am not conscious of my mind in the physical sense, without my body. I cannot separate touching from my tactile organs, seeing from my eyes, or hearing from my ears. I cannot think my body away. Moreover, I am not conscious of my whole personal life at all. How do I know that I was born, though I cannot remember it, and that I shall die, though I am not now conscious of death? How do I know that I am the same person from birth to death? Not by my consciousness, but by knowing the bodies of others—of babies on the one hand, and of old men on the other hand. It is usual to say that the body has not enough unity to be part of the person; the objection is much more true of conscious mind. The truth is that not the unity of consciousness but the unity of action is the important point. The existence of my consciousness is my evi-
dence for my soul. But it does not prove that I am nothing but soul. As a human person, I am body and soul; and the idealistic identification of the Ego with soul or mind, involving the corollary that my body belongs to the non-Ego and is no part of myself, is the redictio ad absurdum of idealism. Lastly, though the personal idealists are right in rejecting the hypothesis of one mind, they are too hasty in supposing that the hypothesis is useless for idealistic purposes. No idealism can explain how we all know the same sun, except by supposing that we all have one mind. The difficulty of our own unity, in other words, is to reconcile the unity of the thing with the plurality of thinkers.

The unity of the sun can only be explained either ideologically

1 For Dr Schiller's views, see further PRAGMATISM.
by supposing it to be one object of one mind, or realistically by
supposing it to be one thing distinct from the many minds which
think about it. The former alternative is false, the latter true.
Personal idealism, therefore, must end in personal realism.

7.—REALISM

1. Metaphysical and Psychological Realism.—Realism is the
view that some known things are bodily, and some are mental.
At its best it is the Aristotelian view that both are substances.
The modern misunderstanding of "substance" has been a main
cause of the confusion of modern thought. Aristotle meant by it
any distinct thing; e.g. I, you, an animal, a plant, the earth,
the moon, God. He calls each of these, as existing apart, a
thing per se (κάθεν αὐτό). It is true that, having divided a natural
substance into form and matter, he called each element "sub-
stance." But these are not primary meanings; and matter, or
supposed substratum, in particular, he says, is not actually
substance (Met. Z 3) or is only potentially substance (Met. H i—2).
In modern times, Spinoza, by his mere mistake, changed the
meaning of "substance" from "existing apart" to "existing
alone," and consistently concluded that there is only one.
Locke mistook it to mean "substratum," or support of qualities,
and naturally concluded that it is unknown. Kant, taking it in
the mistaken meaning of Locke, converted it into the a priori
category of the permanent substance beneath the changes of
phenomena, and even went so far as to separate it from the thing
in itself, as substantia phaenomenon from noumenon. When it
had thus lost every vestige of its true meaning, Kant's successors
naturally began to speak of things as being distinct without being
substantial. But it is true that Locke thought that Nature
and Being is life. Hegel said that spirit is not substance but
subject, which to Aristotle would have meant that it is not a
distinct thing, yet is a distinct thing. Fechner, Wundt and
Paulsen have fixed the conclusion in psychology that soul
is not substance but unity of mental life; and Wundt
concludes from the modern history of the term that substance
or "substrate" is only a secondary conception to that of
causality, and that, while there is a physical causality distinct
from that of substance, psychical causality requires no sub-
stance at all.

The result of this confusion is that the moderns have no name
at all for a distinct thing, and, being mere slaves of abstract terms,
constantly speak of mere attributes, such as activity, life, will,
actuality, unity of mental operations, as if they were distinct
things. But an attribute, though real, is not a distinct reality,
but only a determinant of a substance, and has no being of its
own apart from the substance so determined; whereas a substance,
determined by all its attributes, is different from everything
else in the world. Though, for simplicity and universalization
of thought, even in science, we must use the abstraction of attributes,
and, by the necessity and weakness of language, must
signify what are not substances by nouns substantive, we must
guard against the over-abstraction of believing that a thing exists
as we abstract it. The point of true realism is Aristotle's point
that the world consists of such distinct, though related, things,
and of substances, natural and supernatural. Again,
the method of true realism is that of Aristotle, and consists in
recognizing the independence of metaphysics. The contrary
method is psychological metaphysics, which makes metaphysics
dependent on psychology, on the ground that the origin of know-
ledge determines its limits. This is the method which, as we
have seen, has led from psychological to metaphysical idealism,
by the argument that what we begin by perceiving is mental, and,
therefore, what we end by knowing is mental. Now, there is no
principle of method superior to that of Aristotle—we must
begin with what is known to us. The things best known to man
are the things which he now knows as a man. About these
known things there is some agreement: about the beginnings
of knowledge there is nothing but controversy. We do
not know enough about the origin of knowledge to determine
its limits. Hence, to proceed from psychology to metaphysics
is to proceed from the less to the more known; and the
paradoxes of psychological have caused those of metaphysical
idealism.

The realist, then, ought to begin with metaphysics without
psychological prejudices. He must ask what are known things,
and especially what has been discovered in the sciences; in
mechanics, in order to find the essence of bodies which is neglected
by idealism; in mental science, in order to understand con-
sciousness which is neglected by materialism. With the con-
version that the only fair way of describing metaphysics has been
to avoid putting forward one system, and even to pay most
attention to the dominant idealism, we have nevertheless been
driven occasionally to test opinions by this independent meta-
physical method. The chief results we have found against
idealism are that bodies have not been successfully analysed
except into bodies, as real matter; and that bodies are known to
exert reciprocal pressure in reducing one another to a joint mass
with a common velocity by being mutually impenetrable, as
real forces. The chief results we have found against materialism
are that bodies evolving account neither for the origin of them-
selves, their nature, and their fundamental order of resemblance
and difference, nor for the nature and origin of consciousness
nor even as yet for their becoming good for conscious beings.
Hence we come to the realistic conclusions that among known substances
some are bodies, others are souls; that man is body and soul;
and that God is a pure soul or spirit. At the same time, while the
independence of metaphysics leads us to metaphysical realism,
this is not to deny the value of psychology, still less of logic.
Besides the duty of determining what we know, there is the duty
of determining how we know it. But in order to discharge it,
we must begin by psychology, as we have been led to do by
reasoning, to infer what can be known about God. The
psychological errors, among many others, constantly meet us
in the history of idealism—the arbitrary hypothesis of a sense
of sensations, or of ideas, and the intolerable neglect of logical
inference. Logical inference from sense is a process from sensible
to insensible existence. The former error needs something
deeper than a Kantian critique of reason, or an Averian
criticism of experience; it needs a criticism of the senses.
We want an answer to this question—What must we know by
the senses in order to enable us to know what we infer by reason
in the sciences? Without here aiming at exhaustiveness, we may
bring forward against the dominant idealism a psychological theory
of sense and reason. By touch I perceive one bodily member
reciprocally pressing another in myself, e.g. lip pressing lip; by
touch again I perceive one bodily member similarly pressing
but not another member in myself, e.g. only one lip pressing;
by inference from touch I infer that it is reciprocally pressing
another body similar to my other bodily member, i.e. another
body similar to my other lip. On this theory, then, founded
on the conscious facts of double and single pressure in touch,
and on the logic of inference, we have that Nature is under
knowledge of external bodies, and an explanation of the early
appearance of that knowledge. The child has only to have its mother's
nipple in its mouth in order to infer something very like the
mutually pressing parts of its own mouth. Having thus begun
by touch and tactile inference, we confirm and extend our
inferences of bodies in Nature by using the rest of the senses.
This is not to forget that the five senses are not our whole stock
or to confine inference to body. We have also the inner sense
of consciousness which is inexplicable by body alone. By combi-
ning, moreover, our knowledge of Nature with our consciousness
of spiritual things, we can infer that Nature is not only the
world God. Next, finding that He gives signs of bodily works, but no
signs of bodily organs, we can infer that God is a Spirit.
Finally, returning to ourselves, we can conclude that, while the conscious
in God is Spirit without Body, in us it is spirit with body. This
final distinction between bodily and spiritual substances we owe
to Descartes.

2. The Undercurrent of Modern Realism.—Coming after
the long domination of Aristotelian realism, Descartes and Locke,
though psychological idealists, were metaphysical realists.
Their position was so illogical that it was easily turned into
metaphysical idealism. But their psychological method and
idealism produced another mistake—the tendency to a modicum of realism, as much as seemed to this or that author to follow from psychological idealism. In Germany, since the victory of Kant over Wolff, realism has always been in difficulties, which we can appreciate when we reflect that the Germans by preference apply the term "realism" to the paradoxes of Herbart (1776-1841), who, in order to avoid supposed contradictions, supposed that bodies are not substances, but show (Schein), while "reals" are simple substances, each with a simple quality, and all preserving themselves against disturbance by one another, whether physically or psychologically, but not known to be either material or spiritual face, not known to have the common quality of which the nature of the real consists. There have indeed been other realisms in Germany. Trendelenburg (1802-1872), a formidable opponent of Hegel, tried to surmount Kant's transcendental idealism by supposing that motion, and therefore time, space and the categories, though a priori, are common to thought and being. Dühring, with a similar object, makes matter a common basis. While these realisms come dangerously near to materialism, that of the Roman Catholic A. Günther (1785-1863), "Cartesius correctus," erected too mystical an edifice on the principle of the philosophical hypothesis. Yet Günther's system has produced a school, of which the most distinguished representative is the Old Catholic bishop in Bonn, Th. Weber, whose Metaphysik, completed in 1861, starting from the ego and the analysis of consciousness, aims at arriving at the distinction between spirit and nature, and at rising to the spirit of God the Creator. Other realistic systems are those of J. H. von Kirchmann (1802-1884), author, among other works, of Die Philosophie des Wissens (1864) and Über die Principien des Realismus (1875). Coswin Uphues (b. 1841) professes a philosophy at Halle, directed against the scepticism of Shatto's Discourse on Truth and Hermann Schwarz (born 1864), who completes the psychological view of Uphues that we can know objects as they are, by the metaphysical view that they can be as we know them. But German realism lacks critical power, and is little better than a weed overshadowed by the luxuriant forest of German idealism.

In France, the home of Cartesianism, after the vicissitudes of sensationalism and materialism, which became connected in French Realism with the Revolution, the spirit of Descartes revived in the 19th century in the spiritualistic realism of Victor Cousin. Cousin's psychological method of proceeding from consciousness outwards, and the emphasis laid by him on spirit in comparison with body, prevented a real revival of realism. He essayed to answer Locke by Kant, and Kant by Reid, Maine de Biran and Schelling. From Reid he adopted the belief in an external world beyond sensation, from Biran the explanation of personality by will, from Schelling the identification of all reason in what he called "imperausal reason," which he supposed to be identical in God and man, to be subjective and objective, psychological and ontological. We start, according to him, from a psychological triality in consciousness, consisting of sensation, personal will and impersonal reason, which by a priori laws of causality and substance carries us to the ontological triality of oneself as ego willing, the non-ego as cause of sensation, and God as the absolute cause beneath these relative causes. So far this ontological triality is realism. But when we examine his theory of the non-ego, and find that it resolves matter into active force and this into animated activity, identifies law with reason, and calls God absolute substance, we see at once that this spiritual realism is no very far from idealism. About the teaching of E. Saisset in the spiritualistic school, the influence of Descartes began to give way to that of Leibnitz. Leibnitz has been used both realistically and idealistically in France. He was taken literally by spiritual realists, e.g. by Paul Janet (q.v.). Janet accepted the traditional ontological triality—God, souls and bodies—and, in answer to Ravaisson, who called this realism "semi-materialism," rejoined that he was content to accept the title. At the same time, like Cousin, his works show a tendency to underrate body, tending as they do to the Leibnitzian analysis of the material into the immaterial, and to the supposition that the unity of the body is only given by the soul. His emphasis is on spirit, and he goes so far as to admit that "no spiritualist is engaged to defend the existence of matter." The strength of Janet's position is his perception that the argument from final causes is in favour of an omnipotent rational will making matter a means to ends, and not in favour of an immanent mind of Nature working out her own ends.

The psychological metaphysics of Cousin and of Janet was, however, followed by a way of defending a materialist idealism of matter which has become the dominant French metaphysics. Étienne Vacherot (q.v.) deserted Descartes for Hegel. He accepted from Hegel "the real is rational" without the Hegelian dialectic, by the application of which to the problem of the origin of the divine. Matter he held to be at the minimum of its action, and evolution the "expansion de l'activité incessante de la conscience, c'est-à-dire de la conscience "nécessaire"." In France, therefore, realism is the last view in its attempt to be chief cause and final end. "Let us save," says he in deference to Janet, "the category of the ideal, which applies to nothing real or living. But the most noticeable passage in Le Nouveau spiritueltime (1884) is its contrast between the old and the new, where he says that the old spiritualism opposed spirit to matter, God to Nature, the new spiritualism places matter in spirit, Nature in God (p. 377)." F. Ravaisson (see RAVAISSON-MOLLIER), by his doctrine of "idee-force," took a similar position. But in France, they gave a fresh impulse to the transition from spiritual realism to idealism, by developing the Aristotelian éidos of matter and the idealism of the French materialists. An outstanding example was given by Jules Lachêcher (born 1832) agreed with Ravaisson that beauty is the last word of things, but, under the influence of Kant and his successors, put his idealism rather in the form that all is a sort of a Wandlungsphilosophie of the substance, and the man to whom he attributes this is the above-mentioned Ch. Fouillée (q.v.). He has worked out an idealism which he calls "Néo-criticism," rejecting the thing-in-itself, while eliminating knowledge to phenomena constituted by a priori categories. Phenomena are "representations représentatives et représentées." But he takes the usual advantage of this most ambiguous of terms when he extends it to embrace God, freedom, and immortality required by the moral law. In his later work, La Nouvelle métaphysique (1890), he maintains that each monad is a simple substance, endowed with a representation, which is consciousness in form, phenomenon in matter as represented. In order to explain free will, he supposes, that God and Leibnitz and, perhaps, is not a contradiction, as Fouillée supposes, the French scholastic and the metaphysical realism of evolution by the argument that will to live determines its necessary laws, Bourroux by denying the necessity. His point is, that the world only appears to be phenomena governed by necessary laws, and is really a spontaneity which makes new beginnings, such as life and consciousness, tending to good. These examples are enough to show that the psychological metaphysics of spiritual realism has not been able to withstand the rise and progress of spiritual idealism in France.

In England, the land of Bacon and Locke, the realistic tendency has been more active, and is exhibited in Bacon's Novum organum and De Augenulis scieniurum, English Realism, as well as to a less degree in the Fourth Book of Locke's Essay. After the metaphysical idealism, begun by Berkeley, had evanuuated in Hume's reduction of the objects of knowledge to sensations, ideas and associations, the Scottish school, applying the Baconian method to the study of mind, began to inquire once more for the evidences of our knowledge, and produced the natural or intuitive realism of J. Reid, Dugald Stewart and William Hamilton, followed by H. L. Mansel, as well as by J. Veitch, H. Calderwood and J. M'Cosh, prolonged the existence of the school, in which we may venture to place L. T. Hobhouse and F. W. Bain, author of The Realisation of the Possible (1899), down to our own time. Its main tenet, that we have an immediate perception of the external world, is roughly expressed in the following words of Reid: "I do perceive matter objectively—that is, something
which is extended and solid, which may be measured and weighed, is the immediate object of my touch and sight. And this object I take to be, and not an idea. And, though I have no idea of what it is, I have an idea of what it is not. Nothing that the conscious mind did not always express himself so distinctly. Moreover, he and his successors mixed up so many accidents with the essence of their realism that the whole system broke down under its own weight. The reaction against this Hypothetical Realism. It also supposes much that was doubtful, and much that was ill-adapted to the metaphysics of realism. Yet they thought it the only avenue to metaphysics. It is full of appeal to common sense, and of principles thus relative to our faculties are presented to and decided by the mind, only under modification, determined by these faculties themselves. Not only so, but in his review of Cousin ('Philosophy of the Human Mind,' 1853), he may say that the test of knowledge, argued that "the mind can conceive, and consequently can know, only the limited, and the conditionally limited," that "to think is to condition," that "all we know of either of these, is the knowledge of condition," these we can only know, is the highest generalizations rise above the finite," and concluded that we cannot conceive or know the unconditioned, yet must believe in its existence. Nevertheless, in spite of all this Kantism, he adhered to the realism. He vacated a great deal about our mode of perceiving the external world; but his final view (edition of Reid's works, note D*) consisted in supposing that (1) sensation is an apposition of secondary qualities purely as affectations of the organism viewed as ego; (2) perception in general is an apprehension of primary qualities as relations of sensations in the organism viewed as non-ego; while (3) a special perception of a so-called "thing in itself" is a consciousness of perceiving something external to our organism." Hamilton's views both on the absolute and on perception affected M'Asle and Spencer. They were not, however, received without question even by his followers. H. Calderwood, in his Philosophy of the Infinite (1854), made the pertinent objection that, though thought, conception and knowledge are finite, the object of thought may be argued to be infinite. J. M'Cosh, in The Prevailing Types of Philosophy: Can they logically reach reality? (1891), violently protests against Hamilton's combination of Scottish and German schools. He concludes: "It does not cool the fever which the flimsy theory, that the external world is finite, has thrown away its crutches of impressions, instincts, suggestions, and common sense, and give the mind a power of seeing things directly." He has the merit of presenting natural or intuitive realism in its purity.

The common tenet of the whole school is that without inference we immediately perceive the external world, at all events as a resisting something external to our organism. But is it true? There are three reasons against it, and for the view that we perceive a sensible object within, and infer an external object without, the organism. In the first place, there are great differences between the sensible and the external object; they differ in secondary qualities in the case of all the senses; and even in the case of touch, heat felt within is different from the vibrating heat outside. Secondly, there are so-called "subjective sensations," without any external object as stimulus, most commonly occurring when we are in an excitement, or the feeling of creeping in the skin, and to hoirlination, or the feeling of bristling in the hair; yet, even in "subjective sensations," we perceive something sensible, which, however, must be within, and not outside, the organism. Thirdly, the external world and the senses always act on one another by cause and effect and by pressure, although we only feel pressure by touch. Now, when the thing with which touch is in a state of reciprocal pressure is external, e.g. a table, we feel our organism pressed and pressing; we do not feel the table pressing and pressed, but infer it. The Scottish School never realized that every sensation of the five senses is a perception of a sensible object in the bodily organism; that touch is a perception, not only of single sensible pressure, but also of double sensible pressure, a perception of our bodily members sensibly pressing and pressed by one another, from which, on the recurrence of a single sensible pressure, we infer the pressure of an external thing for the first time. Intuitive Realism is to be replaced by Physical Realism.

3. Reaction to Hypothetical Realism.—The three evidences, which are fatal to intuitive realism, do not prove hypothetical realism, or the hypothesis that we perceive something mental, but infer something bodily. This illogical hypothesis, which consists of incautiously passing from the truth that the sensible object perceived is not external but within the organism to the non-sequitur that therefore it is within the mind, derived what little plausibility it ever possessed from three prejudices: the first, the scholastic dogma that the sensible object is a species sensibilis, or immanent sensible form received from the external world, by the faculty of imagination; the second, his priori, and that the soul as thinking thing can perceive nothing but its own idea; the third, the common assumption of a sense of sensations. But notwithstanding its illogicality, its tendency to underrate Nature as inferred from such idealistic premises, and its certain transition into a consistent idealism, hypothetical realism has, with little excuse, revived among us in the writings of Shadworth Hodgson, James Martineau and A. J. Ballour. The cause of this anachronism has been the failure of intuitive realism and the domination of idealism, which makes short-sighted men begin with the psychology and the psychological idealism of the day, in the false hope that on the sands of psychological idealism they may build a house of metaphysical realism.

Shadworth Holloway Hodgson (born 1832; hon. fellow of Corpus Christi College, Oxford), whose chief work is The Metaphysic of Experience (4 vols., 1868), believing that philosophy is an analysis of the contents of consciousness, or experience, and that this is metaphysics, begins, like Kant, with an analysis of experience. Like Kant, he supposes that experience is concerned with sensations, distinguishes matter and form in sense, identifies time and space, eternal time and infinite space, with the formal element, and substitutes 'synthesis of sensations of touch and sight for association and inference, as the origin of our knowing such a solid material object as a bell. Although he does not agree with Kant that either the formal element in sense or the synthesis of sensations is a priori, yet in very Kantian fashion, through not distinguishing between operation and object, he holds that, in synthetically combining sensations of touch and sight, we not only have a complex perception of a solid body, but also know this 'object thought of' as itself the complex of these sensations objectified. Hence he concludes that 'matter is the name for the sensation-elements derived from both senses, abstracting in thought, so far as possible, from the extension-elements of both.' (p. 296).

Here would you expect him to stop, as the German Neo-Kantian of Lange stops, with the consistent conclusion that all we know of Nature from such data is these complexes of sensation-elements, or Organisms in the Kuhnian meaning. Not so, Shadworth Hodgson supposes something beyond; not, however, an unknown thing in itself causing sensations, but a condition, or sine qua non, of their existence, without being a cause of their nature. In order to make this leap he supposes that we have beyond perceptions a conception of condition. His account of the origin of this conception is puzzling. (p. 358). Whatever its origin may be, it could not, any more than a category of experience, be the same in all people, as it is a relation of perceptions as conditions of one another, seeing that they were supposed to be the whole data, and matter itself to be 'sensation-elements.' But what he proceeds to suppose is that from the conception of condition our perceptions are classed, and that the exceptions needing account for, we infer a real condition, e.g. the solid interior of a bell. What we know, however, of this condition, according to him, has two limits: on the one hand, it is the condition of the only existence of our perceptions; on the other hand, all we know of its nature is our perceptions. Matter thus, which had at first been defined as a complex of perceptions objectified, now turns
out to be a condition without which perceptions would not exist, but whose nature is known only as a complex of perceptions. Finally, according to him, having inferred matter as the condition of our perceptions, we are entitled to infer that the condition of the existence of matter is a priori, and can be inferred only by practical reason from conscience. He averrs that this "metaphysics of experience" is not idealism, or the tenet that consciousness is the only reality. It is, accordingly, pure and a priori notions, as Kant has called them. He suggests that this more extended form of idealism, something like that of Spencer; according, indeed, more knowledge of the distinction between Nature as condition of sensations and God as condition of Nature; but very like in holding that all knowledge, even of God, is derived from its perceptions. We know more, however, about a body, such as a bell, than either Spencer or Hodgson allows. We know, from the concomitant variations between its vibrations and our perceptions, that its vibrations are not more complex than those of our sensations, and this makes its vibrations are not our perceptions, because we cannot perceive them, but are real attributes of the bell. It will be objected that they are merely possible perceptions. But as they really produce our real perceptions, they are themselves not merely possible, but real or actual. A possible cause could not actually produce an actual effect.

James Martineau (q.v.) in A Study of Religion (1888), like Shadworth Hodgson, started from Kant, and tried to found on transcendent idealism "a return to dualism." If there is one thing certain in the Kantian philosophy, it is that all the relations of the most extended form of idealism, it is its assumption that the mind is not extended to things beyond mind. Hegel only extended a priori forms to things by resolving things into thoughts. Mill also protested "against adding, as evidence of the truth of a fact in external nature, the disposition, however strong or however general, of the human mind to believe it." Yet Martineau adopted, as his view of the limits of human intelligence, that Kant was right in making space and time a priori forms of sense, but wrong in limiting them to sensations. But in order to make space a form of external things, Martineau had to take the external in space, by which Kant meant one sensation out of another, when in the very different meaning of the self here and the not-self there. He facilitated this awkward transition by adding to Kant's a priori forms of space and time an "a priori form of alternative causality," or, as he also called it, "an intuition of causality involved in the elementary exercise of perception," which is the key to his whole philosophy. He supposed that this intuition of causality arises when will is resisted, and, further, supposing that causality requires decision between alternatives, concluded that the intuition of will resisted is an intuition of will against will when against other. He supposed that in the decision of one over another, there are two fatal objections to this view. In the first place, the intuition of causality does not require will at all, because we often perceive one bodily matter pressing another involuntarily; a man suffering from lockjaw neither wills nor can avoid feeling the pressure of his upper and lower jaws against one another. Secondly, though causality requires alternatives in the material cause, e.g. wax may or may not be melted, the determination between them is not always a decision of will, but in physical causation depends on the efficient cause, e.g. the fire: as Aristotle says, when the active and passive powers approach, the one must act and the other suffer, and it is only in rational powers that will decides (Met. § 9).

A. J. Balfour, in The Foundations of Belief, being Notes Introductory to the Study of Theology (1895), begins by maintaining that the evidence of the senses is not a foundation of belief, of belief, and then expects us to believe in Nature and in God. He revives the "Acatalepsia of the New Academy. In Part II., ch. i., he makes three assumptions about the senses, and, without stopping to prove them or even to make them consistent, deduces from them his thesis that the evidence of the senses is not a foundation of belief in Nature. He first assumes an immediate experience of a body, e.g. a green tree; and then deduces that the evidence of the senses proves now and then to be fallacious, because we may have an experience indistinguishable from that of a tree but incorrect; and further, that our perceptions are habitually mendacious, because all visual experiences are erroneous, as colour is a sensation while the thing consists of uncoloured particles. This argument from a pure assumption is a confusion of sense and inference. In no case is the evidence of the senses fallacious or mendacious; the fallacy is in the inference.

He next assumes that we have no immediate experience of independent things—that sense perceives sensations, feelings, or ideas; while all else, e.g. a tree, is a matter of inference. On this quite new assumption of a sense of sensations he deduces that, from a perception of these mental facts, we could not infer material facts, e.g. a tree; so that again the evidence of the senses does not afford trustworthy knowledge of the material universe. His deduction is logical; but he has forgotten to prove the assumption, and, therefore, the inference is fallacious. Vision does not perceive a sensation of colour; it perceives a visible picture, e.g. green, which is in the organism, but has never been proved to be a mental fact, or not to be a material fact. So touch perceives not a sensation of pressure, but a pressure which is a material fact in the organism. From a material pressure within we logically infer a material pressure outside. He thirdly assumes an appendix to the second assumption: he assumes that sense perceives mental sensations with succession but without causality, because no kind of cause is open to it of itself. On this thing and to this must be added, but not of causality, he deduces that we could not from such data infer any particular kind of cause, or a bodily cause, e.g. a tree, or indeed any cause at all, or any event beyond perception, without assuming the principle of causality that Nature is uniform in cause and effect over great intervals of time and space. Nevertheless he gives absolutely no proof of the assumption that there is no sense of causality. There is none in the subsidiary senses, because none of them perceives the pressures exerted on them. The primary sense of touch perceives one bodily member causing pressure on another, reciprocally, by virtue of a common kind of pressures caused between the organism and the external world; but without needing the supposed stupendous belief and assumption of the uniformity of Nature, which is altogether ignored in the inferences of the ordinary man. Finally, as touch perceives reciprocal pressure within, and tactile inference infers it without, touch is the primary evidence of the senses which is the foundation and logical ground of our belief in Nature as a system of pressing bodies. Balfour, however, having from unproved assumptions denied the evidence of the senses, and the rational condition of all belief in anything beyond and outside the organism, from which we infer similar particular pressures caused between the organism and the external world; but without needing the supposed stupendous belief and assumption of the uniformity of Nature, which is altogether ignored in the inferences of the ordinary man. According to him, we believe in Nature because it satisfies our material needs, and in God because he satisfies our spiritual needs. But bare need, e.g. a pang of hunger, is no cause of belief beyond itself; and desire, or need of something prospective, e.g. a desire of food, is effect, not cause, of a previous belief that there is such a thing, and of a present inference that it may again be realized. Moreover, when the belief or inference is uncertain, need even in the shape of desire is not in itself a foundation of belief in the thing desired: to need a man is not to believe in getting it; and, as Aristotle said, "there is a wish for impossibilities." It is fair, however, to add that Balfour has a further foundation for the belief in Nature, the survival of the fittest, by which those only would survive who possessed and could transmit the belief. But here he fails exactly as Darwin himself failed. Darwin said, given that organisms are fit, they will tend to survive; but he failed to show how they become fit. Balfour says, given that men believe in Nature, they will survive; but he fails to show how they come to believe in it. Inference from sense is the one result of all belief in oneself, whether it be Nature, or Authority, or God; and it is the one condition of all needs, which are not mere feelings, but desires of things. The result of undermining this sure foundation emerges in Balfour's attitude to the beliefs themselves. He holds that space, time, matter, motion, force, are all full of the insoluble contradictions supposed by Spencer; and that all our beliefs, in Nature, and in God, stand on the same footing of approximations. Hence his really valuable arguments from Nature to God sink to the problematic form—there may be Nature; if so, there is God.
Such is the modern "Acatelpa", which arises from denying the evidence of the senses, and from citing the transfigured realism of Spencer instead of the original realism of Aristotle, about whom ballotour speaks as follows: "It would be difficult, perhaps impossible, to sum up our debts to Aristotle. But assuredly they do not include a tenable theory of the universe."

The Past and Future of Metaphysics—Aristotelian realism is the strong point of Roman Catholic philosophy. As interpreted by Thomas Aquinas, it is now in danger of becoming a dogma. In 1879 Pope Leo XIII, addressed to the bishops the Encyclopaediae eterni patris, which contained the words, "Sancti Thomae sapientiam restituit et quam latissimi propagat." From the Roman Catholic point of view this reaction to "Thomism" was a timely protest against modern metaphysics. It was founded upon a feeling of unsaneness at a growing tendency among Roman Catholic writers not only to treat theology freely, but to corrupt it by paradoxes. One cannot but feel regret at seeing the Reformed Churches blown about by every wind of doctrine, and catching at straws now from Kant, now from Hegel, and now from Lotze, or at home from Green, Caird, Martineau, Ballour and Ward in succession, without ever having considered the basis of their faith; while the Roman Catholics are making every effort to ground a Universal Church on a sane system of metaphysics. However this may be, the power of the movement is visible enough from the spread of Thomism over the civilized world, and in England from the difference between the free treatment of metaphysics by some Catholic writers and that which has arisen under the immediate influence of Thomism. J. H. Newman (1801-1890), maintaining the authority of conscience and the probability of the understanding, concluded to the necessity of a higher authority in the primitive church. W. G. Ward was a philosophical critic of Mill. St. George Mivart, in the Ground-work of Science (1898), maintained the reality of an active causative power underlying Nature, and the dignity of human reason, from an independent point of view. On the other hand, more under the influence of the Thomist reaction, Thomas Harper published The Metaphysics of the School (1890, &c.), describing Thomalsticism, as it appears in the works of Aquinas; and The Manuals of Catholic Philosophy, edited by R. F. Clarke, include General Metaphysics (1890), by John Rickaby, who effectively criticizes Hegel by precise distinctions, which, though scholastic, did not deserve to be forgotten.
